HIGH-PRESSURE FILTER.—Clemens's self-cleaning filters are made for attachment to the ordinary water main, or the supply pipe from a cistern or reservoir. A regulator forms part of the filter, by which the character of the water can be controlled. This is in the form of a dial, the hand working a tap, which allows water to flow in various directions, so that unfiltered or filtered water may be obtained at pleasure, or the animal charcoal composing the filter may be cleaned. They are not troublesome to work, simply requiring to be fixed to a supply pipe and not to be interfered with, except for cleaning. Thus in large houses and public institutions the filter can be attached to the main where it enters the building, and filtered water can be drawn off at any place. The water runs through the filter quite as rapidly as though nothing had been interposed in its course, and it is singular to see pesty water running from one tap, and the same water after passing through the filter issuing perfectly colorless. It is claimed also that the scaling of steam boilers may be to some extent prevented by the use of these filters.—*Iron.*

POINTING WIRE.—The wires are rolled forward under a roller covered with India-rubber and subjected to the grinding action of a revolving stone. The grinding effect is equalized by using a stone curved to suit the roller and conical. The table moves vertically, having a lateral, longitudinal, and dipping movement. Artificial stones and emery wheels are used when required, with continuous streams of sand or emery upon the wires.

Artificial Marble.

A German chemist claims to have succeeded in making a most perfect imitation of marble in a new and very simple manner. He uses carbonate of lime, without any cement or high pressure, and the product is as hard and easily polished as the best marble, and is readily colored, in any shade, even to the most intense black. As the mass, while in a plastic state, is readily worked into any shape or form, its applicability for ornamental walls, floors, furniture, etc., is alleged to be very great. But the inventor especially directs attention to its value in furnishing material for the finer mosaics, which, as is well known, often consist of as many as a hundred and fifty pieces to the square inch. Convenient forms, brilliant colors, and great durability, even in the thinnest stratum of inlaid work, etc., are said to be practicable by this method.

Another ingenious and valuable process in this line consists in turning slabs of slate into imitation marble. The slabs of slate are first surfaced by a planer, and brought to the required thickness; patterns are then laid upon the slabs, and the mallet and chisel work out the required forms and moldings. The marbleizing, however, is the peculiar feature in the operation. The material for this purpose is prepared in a vat and the slab is let down upon the composition, which adheres to the surface of the slate; the slab is next baked in an oven for one night, then has a coating of a peculiar kind of varnish, and, after six repetitions of these processes, it is finally removed and polished, the surface presenting a beautiful appearance. So firmly united to the slate is this coating that it cannot be scaled or clipped off without taking the slaty substance with it. This material is a valuable substitute for natural marble in a large variety of cases.

SHOES BY STEAM.—Army boots and shoes, having the soles screwed to the uppers by means of brass screws, are being manufactured in Philadelphia. Between 600 and 700 pairs are turned out each day, and the work is almost wholly performed by machinery driven by steam. In this system the uppers, after having been cut out by hand, are sewed together by a machine, and the soles pressed into shape by an iron mold driven by steam. The two are slightly attached by hand, and are then taken to the brass screw-machine, which is about the size of an ordinary lathe, and controlled by a single workman. The shoe is put upon a movable arm of steel, and is placed under the upper gearing, to which a long brass wire one-eighth of an inch in diameter is fed. By one movement a thread is cut upon the brass wire, and the screw thus made is forced through the sole and uppers, and is riveted on the inside under a pressure of 1,700 pounds. Just as the operation is completed, the screw is cut from the rod close to the sole, and the operator repeats the action until the shoe is attended with brass screws from toe to heel. The ends of the wires are cut off by two rapidly revolving discs, and they are then filed down to a level with the sole. The heels are cut off by machinery, and have the holes punched in them for the nails at one motion. The nails are put in the holes by boys, and then by one movement of a machine the heels are securely fastened to the shoe. The heels are furnished by means of a turnisher heated by gas and also worked by steam. The edges of the soles are burnished by hand, and the soles are then sand-papered and finished by machine. The whole operation is exceedingly rapid.

AN EVENTFUL HISTORY.—English exhaugaea give accounts of a much enduring 18-ton gun, with which the Committee on Explosives at the Royal Arsenal, Woolwich, are about to make some experiments, for the purpose of testing the advantages to be gained by various lengths of bore. The gun prepared for these experiments has a rather eventful history. It was first of all fired as a 10-in. gun, re-fired, and drilled through and through in various parts, for the insertion of pressure gauges to ascertain the force of the explosion, and the gun in this state sustained some very heavy strains. It was afterwards rifled, and again underwent some extraordinary pressure, and it was subsequently bored up to 11-in., firing a number of rounds with heavy charges, until at length the tube cracked while firing 1,200-lb. shot with 85 lbs. of powder. A new tube has since been put in, and a considerable piece added to the muzzle, so that the gun is at the present a little over 20 feet long, with a bore of 11 in. still. The most advantageous length for land service guns will, no doubt, be ascertained by experiments with this piece of ordnance. Naval guns are of necessity short. The advantage of length of bore is that slower burning, and consequently less dangerous powder, can be used, as the gases have a longer space in which to act upon the shot, which thus acquires its velocity at less expense to the gun.

NEWBOLD'S IMPROVED FURNACE BARS.—These bars are made in various patterns, and consist mainly in placing between the bars or making them hold what the inventor calls "false" bars, which are made of clay or cheap mineral, and the face of which is presented to the fire, and is burnt away, while the "true" bar remains intact. The new bars may consist of two straps, having the clay lying between; or a trough with the clay bar, covering a passage for water; grooved bar with a serpentine windage; a hollow bar for water, with grooves between for the insertion of false bars.

Weekly Variations in Stocks.

(Based on Regular Sales of the most important stocks on the San Francisco Stock and Exchange Board.)

For 6 days ending Wednesday, Apr. 22, 1874.

Mining Stocks.										
This state of the stock market this week has not been encouraging. Prices have been low and sales small. Washoe stocks have fluctuated between the following prices: Belcher between \$76 and \$83; Best & Belcher between \$26½ and \$30; Caledonia, \$22 and \$29; California, \$42 and \$45½; Chollar, \$60½ and \$65; Consolidated Virginia, \$84 and \$89; Crown Point, \$80 and \$90; Exchequer, \$35 and \$40; Gold & Curry, \$22½ and \$26; Hale & Norcross, \$40 and \$45; Kentuck, \$16½ and \$19½; Ophir, \$16½ and \$22½; Overman, \$46 and \$52; Savage, \$61 and \$68; Seg. Belcher, \$84 and \$93; Union Consolidated, \$15½ and \$19; Yellow Jacket, \$80 and \$85. Other fluctuations were as follows: Belmont between \$5 and \$7½; Enreka Consolidated, \$15½ and \$18; Raymond & Ely, \$20½ and \$25; Golden Chariot, \$15 and \$19; South Chariot, \$27½ and \$30. Prominent declines from highest prices of last week were as follows: Best & Belcher shows a falling off of \$2; Chollar, \$2½; Crown Point, \$3; Exchequer, \$4; Hale & Norcross, \$5; Kentuck, \$2½; Ophir, \$3½; Overman, \$3; Seg. Belcher, \$3; Utah, \$2; Raymond & Ely, \$2. Assessments delinquent this month are those of 22 mining companies and aggregate \$459,014. The dividends are four, and amount to \$944,000, leaving a balance in favor of stockholders of \$484,984. The Morning Call gives this week a short editorial about "how mines are assessed," and does not say a word about how dividends are paid. It gives the figures of the assessments levied this month and never mentions the fact that there were dividends also paid.										
and that they exceeded this assessments by the figures given above. The Call claims credit itself for giving fair and unbiased opinions of the state of mining stocks. We have no chronic quarrel with the Call, on account of its reports, as some other papers have, because we care very little for mining stock, but to a casual observer it appears as if the Call was trying to run down mining matters on general principles. At all events when it sums up "how mines are assessed" under a top-head article, it ought in all justities to mining, say in the same article, that the dividends paid during the same time more than doubled the assessments, as was the case. The total assessments this far this year amount to \$2,221,966 against \$2,306,860 in the same time last year. The dividends this year amount to \$3,448,000, while last year they amounted to \$3,231,181 in the same time. There is another fact that the Call might have mentioned, viz., that the assessments for the first four months of this year were less than last; and that the dividends for the first four months of this year were more than last.										
New Diggonos.—The Chinese have struck diggings in the channel at the mouth of Conner creek (O.) that pay six or eight dollars per day. The diggings are deep, being evidently the old channel of Snake river. The gold obtained is coarse, some pieces weighing as much as 16 oz.										
Diggings have been struck in British Columbia, on Wesley har, which are said to pay from \$20 to \$50 for the day's work of three or four hours to the hand.										
Tin to the amount of from 120 to 130 tons per week is now sent down to port from Stanthorne, Oranienburg.										

INYO COUNTY.

PANAMINT.—*Independent*, April 11: A 10-stamp mill is being erected on Jacobs' Wonder, and another, it is believed, is to be at once built for the Morning Star, owned by Senator Perkins' company. Three shafts are at work on Stewart's Venus, working on a 100-ft. contract. They are now down about 40 ft. The depth attained in the Wonder is only about 36 ft. Many other locations are being prospected to about the same extent, and so far not one but with the most encouraging and materially improving prospects.

EXTENSIVE SALT MINE.—A gentleman from Panamint district, designs to secure by United States patent a portion of a most remarkably extensive salt deposit, located about 10 miles from Panamint. The salt, to the depth of about a foot on the average, covers an area of about a mile and a quarter square, and is a very fine article. And, speaking of salt mines, immediately north and in sight of Cerro Gordo there is a valley along the foot of the Inyo range, which, for several miles square, is covered to about the same depth as the Panamint deposit. The article, ready for use, can be shoveled up by the ton in either of these places.

MONTEREY COUNTY.

Mining Prospects.—*Advance*, April 18: Mr. F. A. Gibbs, formerly engaged in prospecting for quicksilver mines in this district, is at present in New York, but is about to return here, and will immediately open some promising mines within a few feet of Hollister.

NEVADA COUNTY.

WYOMING MINE.—*Transcript*: We saw specimens of rock from the 300-ft. level of the Wyoming mine, which is very rich in sulphurets, and is said to be worth at least \$50 per ton. The ledge on this level has just been cut, and it is 3 ft. thick at the depth named. Every indication is now good for the mine to pay well.

Success.—*Tidings*, April 18: The New York Hill mine still holds good, and Mr. Delano the owner, informs us, the further he drifts on the ledge the richer it becomes, and we judge it so, from the appearance of the pieces of rock he brought us on Thursday of this week.

Idaho.—The Barleigh drill is to be introduced into the Idaho mine. They are worked by compressed air. Four are sent for, and in about 6 weeks will be in use.

PLACER COUNTY.

Mining.—*Herald*, April 18th: Since the white man first disturbed the solitude of the Sierras with the clatter of his pick and shovel, there has not been known so much snow in the mountains, this season of the year, as at present. This snow is now melting, which affords the miners an abundant supply of water. As a consequence, all the mines are working full forces. But what will make this much better than ordinary seasons, the supply of water will last until later in the summer. In short, the indications are that from the favors of Providence, Placer is bound to flourish, for the next twelve months at least.

Mills.—The quartz mills below town are hammering away on rock which is paying some ten, some twenty, and some as high as \$45 per ton.

Coal.—The coal mine at Lincoln is doing considerable business already. Nine carloads were shipped the other evening to Sacramento.

SIERRA COUNTY.

Goodyear Hill Mine.—*Messenger*, April 18: Work is being vigorously prosecuted on the above mine, located on or near the old Florida House trail, on Goodyear Hill.

Manson's Quartz Mill.—Work is being pushed on Manson's Quartz Mill, at the foundry, the castings being nearly all made.

TULARE COUNTY.

From the Mines.—*Times*, April 18: Mr. F. Hunt, Recorder at the new mines, informs us that he has arrived at the District and finds some of the leads to be very rich. He also states that quite a number of miners are now blasting and opening up some of the leads, and others are prospecting for new ones.

TUOLUMNE COUNTY.

Independent, April 18: Jas. Holmes & Lake O'Hara have a good placer and quartz claim at Union Hill, near Springfield. They are down 70 feet. One-half day's work showed 7% ounces of gold.

John Sloom & Jim Thomas, two Tuolumne amalgamators, have started the Golden Gate mill running.

The mines of Colombia and vicinity have now plenty of water and are all busy. Lang & Colby in December and February took out 243 1/2 ounces of gold.

They are still pumping on the Rawhide mine.

TRINITY COUNTY.

Minesville.—*Journal*, April 18: In this district the miners are all busy and doing well. Steve Turner and Dick Killings have found good prospects on the Stuart Fork, near VanMatre's house. Mr. VanMatre bought the interest of Alex. Campbell in the Dutch Gulch claim where the big gold comes from. He informs us that last Saturday afternoon they picked up \$110 in nuggets, and are every day expecting to find a piece of several pounds weight.

Lewiston.—Olney Phillips informs us that Lewiston district will not be behind any other in the county in the amount of gold taken out this season. Olney says he has the best claim in the county and is running it in good shape. The Little Giant is doing good work and saving much expense. Ten dollars and a half a day,

he tells us, does more work now than could be done for \$30 per day before he got the new rigging.

In the Basin.—The miners in Weaver Basin now have plenty of water, and are running it through their flumes well-filled with dirt. Much more bed-rock will be stripped this season than for several years past.

VENTURA COUNTY.

Signal, April 11: Mr. Sardin has some very fine specimens of placer gold washed out by the Chinaman who recently returned from the Piru mines.

Nevada.

WASHOE DISTRICT.

Crown Point.—Gold Hill *News* April 16: Daily yield of ore 550 tons. The ore breasts on the 1,000-ft. level are yielding finely and promise to extend upward through the entire 300-ft. level and perhaps into the 800, affording a vast amount of fine ore for extraction from that portion of the mine. The east ore vein, which on the 1,200-ft. level was only seven or eight ft. in width, was struck 28 ft. of the west vein. On the 1,300-ft. level it had inclined to the eastward until it was 60 ft. east of the west vein and had gradually widened to 37 ft. When the east cross-cut had been run 80 or 90 ft. on the 1,400-ft. level, many gave up the hope of again finding that portion of the ledge, thinking that it had pinched out; but Superintendent Samuel Jones, knowing the inclination of the east body, thought differently, and in spite of all opposition pushed the drift ahead, striking the ore richer than ever at a distance of 101 ft. east of the west vein. This body of ore has been penetrated 60 ft., and promises to open out over a hundred ft. in width, all of the finest quality of ore. Ore stops are being opened in this body, and the extraction of the ore has already been commenced.

Globe Consolidated.—The connection has been completed between the up-raise from the tunnel and the winze from the old works, thoroughly ventilating all the upper portion of the mine, and giving a means of soon commencing the extraction of ore. This winze has passed a distance of 170 ft. upward through ore to reach the old upper works, where the ore had been extracted and milled to the depth of 300 ft. from the surface. The old Globe tunnel will now shortly be extended.

Ophir.—The south drift on the 1,300-ft. level, running to connect with the north drift from the Virginia Consolidated, is fast approaching completion. There seems to be some difference in the depth at which the two drifts were started, and a raise is now being made to complete the connection. No prospecting or cross-cutting will be done on the 1,700-ft. level until the south drift shall have reached the south line of the mine.

Emm.—The property of the Erie Silver Mining Company consists of 1,500 feet in length by 600 feet in width, in the southern extremity of the Comstock, and immediately adjoining the old Pony Express ground on the south. The Florida and Pony Express developments, adjoining and in the same ledge, are highly encouraging for the prospects of the Erie.

Gould & Curry.—Sinking the double winze on the 1,700-foot level is progressing finely, the Burleigh drills driven by the new air compressor working with the utmost perfection and enabling much better progress to be made than by the old hand style of work.

Union Consolidated.—The main north drift on the 1,300-ft. level from the Ophir shaft has struck the west wall of the ledge along which it is being driven toward the Union Consolidated ground. The face of the drift shows some excellent ore indications, which are rapidly improving in appearance.

Chollan Porosi.—Daily yield 100 tons of ore, the assay value of which is \$32 per ton. There is no change to report of the ore producing portion of the mine, except a gradual improvement in the Belvidere section.

Sierra Nevada.—Daily yield 60 tons of ore, keeping the mill steadily running. There is an abundance of low grade ore in sight; prospecting for more in the upper portions of the mine is going on as usual. The new shaft is down 350 feet.

Sutro Tunnel.—The header of the main tunnel is still being driven ahead, and hereafter better progress will be made, as shaft No. 2 is nearly down to the tunnel level. It will probably be completed on Saturday next, and thenceforward the tunnel can be worked both east and west along its line, from the bottom of the shaft, thus giving three working faces and three times as good opportunity for working as there has been heretofore. Shaft No. 3, which is located between shaft No. 2 and the header of the main tunnel, was abandoned some weeks since, it being found that the tunnel could be, with present facilities, worked past it before it could reach the tunnel level.

Yellow Jacket.—The main incline is to-day 40 feet below the 1,640-ft. level in good sinking ground in the west wall, and progressing deeper at the rate of 15 feet per week. It will take about two months to bring it to the 1,740-ft. level, 280 feet in vertical depth below the Sutro tunnel level. When the 1,740-ft. level is reached it will be opened and properly developed, as the indications above in the mine warrant the expectation of something particularly good at this deeper level.

Baltimore Consolidated.—The water has again been drained and work resumed in the bottom of the shaft, notwithstanding there is a strong flow of water that at times will almost entirely stop the work for two or three hours,

when the pumps will again get the better of it and the sinking go slowly on. The erection of the new hoisting machinery is making steady progress.

Bellevue.—Daily yield 550 tons of ore, from the 1,000, 2,000, 1,300 and 1,400-ft. levels. The ore taken from the 1,400-ft. level is of the same quality as that taken from the level above. The ventilation on the level is good, owing to the fact that the cold air passing down the Crown Point shaft finds its way to this level.

Leo.—The main adit is being driven steadily ahead into the hill, following the ledge. The vein water is wide and the rich ore streak has again widened out, being to-day about 20 inches in width, with good indications of still further widening.

Savage.—Sinking the main incline is making steady progress, the rock in this bottom blasting and working finely.

Imperial-Emprise.—The main incline is down 80 ft. below the 1,850-ft. level, the bottom in good ground and sinking making good headway. The main east drift, on the 1,850-ft. level, is making excellent headway, and is undoubtedly passing through the west wall of the ledge.

Genesee No. 2.—This location is a very eligible one, in Spring valley, and adjoins the Daney on the north. It is an old location, but work is now being done to develop it. A new double working shaft is commenced, which is now down 45 ft. in good solid quartz, assaying as high as \$35 to the ton.

Knickerbocker.—The pumps are all completed and in good running order. Good speed is being made in draining the shaft of water. The air pipes are being extended from the shaft into the west drift at the lowest level for the purpose of resuming work in the face of the drift at the earliest moment.

Miner.—The new hoisting machinery is completed and everything working with the utmost perfection. Hoisting the water from the shaft has been commenced.

Bricker.—Prospecting work goes on as usual, and the mill is being put in order for another good run.

Hale & Noncross.—The prospecting on the 1,900-ft. level is confined to two cross-cuts south of the incline and one near the north line. The cross-cuts south have up to to-day been passing through alternate streaks of quartz, clay, porphyry, and seams of rich ore, but showing no body of ore that will pay for extraction.

Julia.—The main south drift, on the 900-ft. level, is now in 800 ft., still following the west wall of the ledge. Cross-cuts are being run 40 or 50 feet apart as the work progresses, for the purpose of determining the quality of the ore. The east cross-cut from the main south drift on the 1,000-ft. level, has struck a solid clay wall which it is not yet through.

Caledonia.—The station and tanks for catching the water have been completed at the fourth level and a west drift started to connect with the air winze from the third station-level.

Florida.—The Florida Silver Mining Company's ground, which is the recently segregated north half or 1,300 ft. of the old Pony Express claim at the south end of American Flat, under the superintendence of J. J. Nagle, is giving a good showing at the present time in both the north drift and the winze, some very good assays being obtained.

Overman.—The main west drift on the 1,200-foot level is still being driven vigorously forward, the rock in the face blasting and working finely.

Kentuck.—The main north-east cross-cut on the 1,000-foot level from the Crown Point is in 120 feet, the face in a mixture of clay, quartz and porphyry. This drift is being run to connect with the Yellow Jacket works. As soon as that connection is made and ventilation obtained, cross-cutting the ledge will be commenced.

Utah.—The south drift from the main west tunnel is still continued to the southward, finding occasional bunches of quartz, but nothing of a very promising character.

California.—The north drift, from the Virginia Consolidated on the 1,300-foot level, is making steady headway, and will probably connect with the south drift in the Ophir in four or five days more.

Rock Island.—New hoisting machinery has been ordered from San Francisco, and the first shipment will probably arrive at the mine by the fifteenth of next month.

South Star.—New shaft down 92 feet to-day, in pay ore all the way, assays running from \$25 to over \$250 per ton. The rock is hard, but blasts well, allowing of good progress. No water encountered as yet.

Segregated Rock Island.—Another cross-cut, No. 2, has been run into the ledge, which shows a steady improvement in the quality of the ore as the work progresses to the northward.

Woodville.—Sinking the main shaft is making slow headway, the rock in the bottom blasting hard and tough. It is to-day down 23 feet below the 300-foot level.

Nevada.—The ore in the south drift, has improved considerably during the past week, both in quality and quantity. The ore in the face is now four feet wide, of good milling quality, with an average assay taken from car samples of \$27.36 per ton.

Pictou.—The tunnel is in over 400 feet, and is being driven steadily ahead with favorable indications. The sinking of a shaft is proposed as soon as this tunnel shall determine the position of the ledge, and the best place for sinking.

Lady Bryan.—Sinking the new shaft is making rapid progress, the rock in the bottom blasting finely. It is now down 75 feet. The erection of the new hoisting works building has commenced and is making rapid headway.

Tyler.—Sinking the main shaft is making excellent progress. It is now down 70 ft. below the 300-ft. station.

Alhambra.—The new hoisting works building is completed. The engine and other machinery is in place, and it is expected that everything will be in readiness to resume sinking the shaft in about 10 days' time.

Chapin and East, Comstock.—Owing to unexpected increase of water, work is suspended in this shaft until arrangements are made for a suitable pump to enable the work to progress advantageously.

Sutro.—Increase of water having seriously impeded the advantageous working of this mine, the expediency of sinking a new working shaft is under consideration by the management.

Crown Point Express.—Work temporarily suspended owing to influx of water. Better pump arrangements required.

Silver Hill.—The machinery is again in good running order, and work has already been resumed in the mine.

New York Consolidated.—The new pumping machinery, and repairs to this shaft being about completed, the works will start up again next Monday, when sinking in the shaft will be resumed.

Lady Washington.—The repairs to the main shaft, and the erection of new pumping machinery, are going ahead vigorously, and the works will start up about the first of next month.

South Comstock.—Incline down 20 ft. below the 150-ft. level, sinking in the foot wall material, which is clay, with a fine looking streak of quartz. No water interferes.

Arizona.

Miner, April 10: Col. H. A. Bigelow called at our office, yesterday evening, when, in the course of conversation, we learned that himself and partners in the Bashford mining claim, Lynx creek, have in a very short time taken out \$788.

Mining Prospects.—*Citizen*, April 11: We noticed last week the rich discovery made in Morgan mountains by Pat Morgan and others. It is said to be parallel to and near a monster lode of galena ore that contains a large percent of silver, and it is thought by some to be a part of the same vein. The walls of these lodes are said to be regular and give evidence of being true fissure veins, of great value.

Thos. Gardner brought in about a ton of very rich ore from the Trench mine this week, which the owners intend to send to the Colorado smelting works for reduction. The Trench lode is increasing in width and richness as they go down on it.

J. J. Muller and Sam'l Hughes returned this week from Sierra mines, south of Tucson. Mr. Muller is a scientific and practical miner, and says that he was surprised to find such quantities of rich ore.

Coal.—*Statesman*, April 16: The Boise City Coal Co. are very much encouraged in their prospecting on the Idaho road, above the Garrison. Fred Dangel, one of the company, showed us a specimen rock containing portions of coal, also several small pieces of very good coal, found about 20 feet below the surface, with good indications.

Montana.

Blackfoot.—North West, April 7: Mining has already been commenced by Tarry & Co. and Hagan & Co. near Blackfoot, and by Kermally & Co. further down Ophir. A considerable number of the miners who have been away have returned, and everything betokens an early general resumption of work.

Oregon.

Summit.—*Baker City Herald*: The quartz which is now being taken out of the Summit mine at Augusta, is of a richer quality than has ever before been produced in that mine. We are inclined to the belief that there are no mines in Baker county which have been fully developed. But much will be done the present season tending that way.

The pinch in the James Gordon ledge, Baker county, has been worked out, and now there is a large vein of quartz developed, which is far richer than any heretofore taken out.

The miners of Eastern Oregon are ready for Old Sol to pour down his beams that the water may pour down into their ditches from the snowy mountains.

Miners in Jackson county are beginning to feel the failing of the water in the creeks and ditches, and many of them will soon be compelled to lay down the shovel for another season.

Washington.

Yakima Mines.—*Union*, April 4: We have been shown a private letter written to a gentleman in this city, from a friend in the Swack mines, in which among other things it speaks of mines having been struck down on the Yakima river at the mouth of the Swack. They prospect well, and it is believed they will prove to be good paying mines. At the newly discovered camp there is no snow, and there is a plenty of water, and the miners are going ahead and are busily engaged in opening their claims. In the Swack mines the nights are still cold and there is not much doing. Snow is from one to three feet deep, and is settling and melting a little. The writer seems to have all faith in the mines ultimately paying rich, both in placer and quartz mining.

Agricultural Progress.

Farming is acknowledged to be progressive, even by farmers. Whatever changes come about are made usually by insensible gradations; but in the course of a few years we are often surprised to see that some innovation, which at the start had perhaps been ridiculed, has wholly ousted the old modes. Never before the present have farmers been so willing to concede that there was any room for improvement. Says the *Western Rural*: The progress in agricultural art within the last fifty years, although not as marked as that made in the mechanic and other arts, is nevertheless fully indicative of the increasing intelligence among the agricultural masses. When we look back upon the improvements in plows, harrows, reaping, mowing and threshing machines, and then to the old-time forks for handling hay and grain, and the many other tools that have been consigned to the tooth of time or utterly forgotten, we may well feel proud of the improvements that now enable the farmer to plow, sow, reap and garner away, enabling one or two individuals to do the work that before required the work of many laborers to accomplish.

The farmer, if so disposed, may now take his riding plow and turn the soil. He may harrow by a machine suspended on wheels, roll, sow, plant, cultivate, reap, bind, stack, thresh and sack his grain by the use of mechanical power. Steam carries the grain from the warehouse or the railway car into the immense bins, from whence it is again distributed, by the same power, to the railway or the ship for transportation to the consumer at home and abroad. All this has been made possible by improvements within the last thirty years.

In live stock, the improvement has been particularly marked, as an examination of our favorite breeds of horses, cattle, sheep, swine and poultry will amply attest. In fact the question is now often asked where is the limit beyond which improvement cannot go.

One of the important questions in this connection is, how has it come about? The only answer is, principally through the education of individuals to the profession in life which they are to follow. An important factor in this connection, however, is the habit of independent thought that has become prevalent among the masses, through the system of universal and free education inaugurated, not only in the United States, but in other enlightened countries, imperfect though it be as yet. A notable fact in this connection is also worthy of mention; that is, the mass of the more important inventions of the day is the result of the brain work of the three nations where education is most advanced, viz: the United States, Germany and Great Britain.

Besides the improvement of farm machinery, agricultural art itself, as connected with the management of the soil, has made no less rapid strides than has been shown in the invention of agricultural implements and machines. We understand far more now about the nature and proper conditions of the soil, and this knowledge is every day becoming intensified. We have done with much that was purely theoretical, and are working upon true principles founded upon experiment, bringing out facts, the foundation of all science.

We should realize the importance of practical experiments, as presenting and substantiating the truth or falsity of theory continually. Our agricultural colleagues are, some of them, doing something in this direction now; so are our agricultural and horticultural societies. Their efforts should be supplemented in every direction by practical workers on the farm, and the result should be made known through the press, that agricultural art may make equal progress with the improvement of agricultural machinery. Many important facts are lost to the public every day, from the feeling among practical men that their discoveries may not be entirely correct, or at least that subsequent experiment may modify the proofs so far as collected. This is certainly true, but the result of one experiment, or one set of experiments, almost always gives rise to others, carried forward in parallel lines. Therefore give us facts, even if they be simple ones only, for it is through these made public that we must expect the greatest progress in the improvement of agricultural art.

One of the principal reasons for the rapid advance in the industrial arts, as distinguished from agriculture, is that no sooner is a result arrived at by practical experiment than it is chronicled in the technical journal, devoted to the trade. Farmers should see to it that their own technical journals, the agricultural papers, are made the means of preserving from oblivion any fact arrived at in the exercise of their daily labor.

VALUABLE ARRANGEMENT.—A large force of workmen were yesterday engaged on Union street, between C and D streets, Virginia, in digging a deep trench in which is to be laid a pipe for conveying water to the Virginia Consolidated works. The pipe is four or five inches in diameter, and with the great pressure there will be on it is capable of carrying a great volume of water. Hydrants are to be placed at convenient points about the works, connected with this pipe, with plenty of carbolized hose ready to attach at a moment's warning. This will be a very efficient protection, in case of fire, either to the works or the surrounding buildings.—*Gold Hill News*.

A Novel Wire Fence.

Wire fences have many points of advantage. They are cheap, where lumber is expensive, and are light, portable and easily put up; and, besides, are of attractive appearance when carefully constructed. The great drawback has been the liability of the wires to sag when expanded by heat, tighten when contracted by cold, and to sag when strained by the efforts of animals to pass through. When attached to rigid supports, such strain stretches the wires so that they remain taut.

In the fence herewith illustrated, known as the Wakefield wire fence, invented by Mr. Chas. A. Wakefield, of Pittsfield, Mass., means are provided whereby, when the wire expands by heat, the increase in length thus occasioned is taken up. When the wires contract by cold, or when tension is put upon them by the efforts of an animal to pass through them, they yield without stretching, at the same time that they afford sufficient resistance to stop animals from passing. A very brief examination of the engravings will show how this is accomplished.

Fig. 1.

The wires are made fast only to the end post at one end of a section of fence. They are then passed loosely through all the intermediate posts to the other end, and are there attached to a set of whiffletrees and an evener. These are attached to a chain and pulley which suspend a weight of sufficient magnitude to prevent the wires from yielding when strained by cattle, and yet allow them to yield before that amount of tension is exerted which will permanently stretch them. This fence has been tested thoroughly for four years on the inventor's farm, and has proved to be not only cheap, but durable and efficient.

Figures 1 and 2 represent a longitudinal

Fig. 2.

elevation of one end of a section of fence constructed in accordance with this invention. Figure 3 represents a transverse elevation of the opposite end, showing only the end posts, the equalizing pins, and the wires coiled around said pins. Pieces of the posts are represented as broken out, uncovering the upper pin.

Fig. 3.

B, B, represent the posts; C, C, a continuous rail of wood forming the top of the fence; D, D, the wires; E, E, the round, and F, F, the square section of the pin; H, H, the weights; I, I, the board in Fig. 1, and the pin in Fig. 2, supporting one end of the frame and timber on which the weights are placed; K, K, the chain on which the other end of the weight frames are suspended; L, L, the pulleys; M, M, the eveners; N, N, an ordinary, and R, R, in Fig. 2, a secondary, or short pair of whiffletrees. Fig. 4 shows one of the equalizing pins.

The set in Fig. 2 is arranged like a three-horse, and in Fig. 1 a two-horse evener. An evener may be arranged for a fence of any given number of wires, and have the strain equal on each. The fence may be made with, or without, a rail of wood on top. The advantage of the rail is, that cattle will see it sooner, and be less liable to run into it.

An immense quantity of lead is said to exist in the immediate vicinity of Sherman, Texas.

Coal Ashes.

Fertilizers are becoming nearly as numerous in kind as they are rare in quantity. Farmers are apt, and with reason, to distrust the different substances and compounds which are so vigorously supported by their special advocates; and have little faith in new and experimental modes of increasing the fertility of soil. As a rule, too much is claimed, at the outset, for a particular agent; too much is expected of it and its application is assumed to be too general hence, when it is tried for purposes which it cannot possibly influence, failure and disappointment ensue, and it is denounced as altogether worthless.

The idea of utilizing coal ashes as manure is not a new one. Such a dressing has been successfully applied in many cases for years, and we have previously called attention to its value. After all, actual trial is the only way to determine the real merits of anything; no amount

of theorizing is so convincing as a single, fairly conducted test.

Last year a Pennsylvania farmer, who had always believed that coal ashes had a value for agricultural purposes, and had advocated the free use of them, particularly on limestone soil, determined to get closer to the root of the matter, and test their value fully. He had a plot of ground on which he had been unsuccessful for several years in raising good potatoes. The soil was in the best condition always. The tops did well. In the spring he had a plot of ground scored about six inches deep, placed the cut potatoes in the bottom, and filled up with coal ashes. The plants grew finely, notwithstanding

the dry weather. The tops did not fall over even after the weather changed, and he stated that he secured a crop of the very best potatoes for the table he ever raised.

The second experiment was with onion seed and coal ashes. He put out five good sized beds in seeds. In four the seed was covered with soil; the fifth he covered with sifted coal ashes. The result surprised every person who knew of the experiment and watched its progress.

A third experiment was started on seed which promised utter failure to those who looked on; but the result proved quite as successful. He says: "I have abiding faith in coal ashes and am ready to use all I can purchase." The *Rural Home* cites a case in point, which, if it does not prove too much, is at least a severe strain upon ordinary imagination, as follows:

"In 1857, a man went to Palermo, N.Y., and bought sixty acres of light, sandy land, with here and there a little pertaining to gravel. He paid \$1,800 for it. He knew nothing about farming, being a machinist by trade, and never held a plow. After paying for his land, he had \$200 left. He began, and found his land was worn out. His first crops were—wheat, five bushels per acre; rye, eight bushels; potatoes, seventy-five; corn, mere nothing. The second year was even worse. He had to hire part of his sheep pastured out; he could not hold his own. But being a man of excellent judgment, and a great reader, his good judgment, aided by theories, carried him through. He began by buying ashes and plaster; would draw potatoes fourteen miles to Oswego, and load his team back with manure from the livery stables. His crops increased. His ashes were spread correspondingly thick. He raised, principally, potatoes and wheat. Now, 2,000 bushels of ashes per year is about what he buys. His potatoes, for several years past, average 250 bushels per acre; his winter wheat, 30 bushels and over; and he has saved, from his farm alone, till he now holds \$12,000 in bank stock, and would not sell his farm for \$100 per acre. He sold, in 1869, of potatoes and wheat, over \$2,300 worth. He is known as the best farmer in this county. Yet when he began buying ashes, old farmers shook their heads and said: 'He will know better when he has farmed it as much as we have.'"

The moral to this nice little story is that a light, sandy loam and an abiding faith in the books will carry a man anywhere.

When similar experiments are made with any fertilizer, let the information gained be published, with verification, for the good of others. After the results, there is time to look for a theory. With ashes the explanation is simple: besides the mechanical effect in loosening heavy soil, they supply valuable mineral salts, which enter into the composition of plants.

Deserted Mines.

A new exchange, the *Rocky Mountain Miner and Mechanic*, says: In passing through the various mining districts, on a tour of inspection, the singular feature of a great many deserted holes in the ground attracts attention. Some have been sunk to a considerable depth, 50 or 60 feet perhaps, while others are but shallow excavations. That these holes were dug in search of the precious metal is evident, but the question—why there is nothing being done with them—naturally arises.

In some cases an unusual inferior quality of ore is found near the surface not exceeding \$50 in value per ton. After a few tons have been taken out, a shipment is made, and from the returns it is learned that the yield of the ore was only enough to pay for the hauling and working; the expense of each ranging from \$20 to \$30 per ton, leaving the miner a zero for the reward of his toil. Although every evidence is manifested that the lead contains rich quartz in large quantities if opened to a required depth, the poor miner is forced to abandon his discovery for want of means to develop it.

In other instances where the mine has been opened to a considerable depth, and is turning out good pay, a formidable barrier makes its appearance, and the miner finds his shaft rapidly filling with water. He brings to his assistance all the available means which he is pecuniarily able to procure—endeavoring to take out the water and prosecute his work. He is compelled to employ much extra help, and after having expended his limited capital in this way, he is forced to desert his antiprize.

It is no exaggeration to say that over a hundred valuable mines, rich in gold and silver, within half the number of miles from Denver, are lying idle, which might be worked with large profit, if properly managed.

When the ore is of a low grade, machinery is needed to dress and separate it at the mine, obviating the hauling of worthless rock long distances over steep roads; and where water is the barrier, machinery is necessary to profitably contend with that obstruction.

A small engine of about 10 or 12-horse power would be of sufficient size to run machinery for dressing the quartz, work the shaft and keep pumps in operation, if necessary. Such an engine, together with the machinery and pumps, could be put on the ground and set up ready for use at an outlay of \$3,000 to \$5,000; and in addition to its service in working the machinery, would save the labor of \$2,000 to \$4,000 per annum.

In every instance where an experiment has been made with machinery for these purposes, it has proven a complete success.

This is a subject of much conversation in the mining districts, but the question is how are men of means to be made interested, and capital brought to the assistance of experience and labor, in developing our untold wealth of mineral resources?

The field is open, the harvest is waiting. Come forward, men of enterprise, invest your money, and if prudence is exercised, success will crown your efforts.

Coal in Amador.

The *Sutter Independent* of April 8th has the annexed on this subject: That we have a coal belt running through our county which only needs development to render it an important source of revenue to us, hardly needs to be proven, since several mines have already been opened upon it with extremely favorable results. It is true that the coal heretofore taken from these mines is not of uniform character, some of it partaking more of the nature of lignite, or wood not yet completely metamorphosed into carbon, yet much of it is fully equal in quality to Rocky Mountain or Mount Diablo coal; and the probability is that when that portion of the vein which has been completely prospected from the action of the atmosphere is reached, the whole of the deposit will be found to be of improved quality. But whether this be the case or not, there is now sufficient quantity of coal of good quality opened up to create a large business, when once a cheap method of transportation is obtained to market. It is estimated by those who have examined into the matter, and who have no interest in misrepresenting facts, that upon the completion of the Lone Railroad, at least 200 tons of coal from our mines can be shipped daily, for which a market can be easily found in Stockton, San Francisco and other places. This coal can be sold, with a fair profit to the shipper, at \$5 per ton in Stockton, and \$6 in San Francisco. Numerous tests have been made of the quality of this coal with the most satisfactory results. For blacksmithing purposes it was found to be equal to coal which costs four times the amount this can be sold for, and for fuel in manufacturing, it was found to be equally well adapted.

USEFUL INFORMATION.

The Waste of Oil.

If there be one thing more than another which is likely to be wasted about a workshop, it is oil. This waste is not wanton or even intentional, perhaps, but those who do not have to pay for oil seldom realize how important it is to economize it, and it is not often they know how to use it properly. It would not be extravagant, perhaps, to assert that half the oil used about machinists shops and metal-working establishments in general, is wasted. For example, if a workman wishes to oil his file for finishing, he will pour a stream over its surface, allowing two thirds or more to drip on the floor, when the file could be sufficiently moistened by a small bunch of waste, or better, a small sponge saturated with oil, without wasting a drop. If a hole is to be tapped in iron, whether cast or wrought, the workman too often prefers lubricating oil to patience and "elbow grease," and pours on oil until he saturates the substance or fills the pores of the iron. In ordinary cast iron, a tap, properly made or judiciously used, can be run without oil, or with a very small quantity, and in this work, as in many other processes, a saponaceous liquid is equally as effectual and much cheaper.

It is an old and worn out notion that almost every operation on the metals, and almost every use of a tool, must be accompanied with oil; neither is it correct that oil alone is a lubricant. Holes may be drilled and tapped, and surfaces finished without the use of oil, although some lubricant may be necessary. The addition of oil to an already clogged file, milling tool, saw or rotary cutter, is not only a waste, but is no aid to the progress of the work. Either of them may be quickly and effectually cleaned either by wiping with waste, combing with the card, or heating over the forge fire; when they will do the work required much better than if they had to overcome the resistance of a body of viscid oil.

In the lubricating of shafting, also, great waste is occasioned. Where shafting is suspended in ordinary boxes, most of the oil leaves the journal almost as soon as poured into the box, and finds its way, dirty and fouled, into the drip pan; once there it is nearly worthless for shop use. Gummy, dirty oil, charged with foreign matter, half oxidized by exposure to the atmosphere, although often used for tapping and screw cutting, is unfit for even those purposes. It corrodes the taps and dies, and by its adhesive quality adds greatly to the power required to do the work.

We might add other illustrations of waste of oil, or extravagance in its use, but this article is intended to be suggestive rather than instructive. Every manufacturer can, by investigation and experiment, find out what proportion of the oil used in his business is wasted, and by a judicious overseeing he can usually effect an important economy in the amount annually consumed. It is economy, or a disregard of it, in such little matters that often makes the difference between profit and loss to a manufacturer.—*Iron Age.*

TEMPERATURE REQUIRED TO HATCH EGGS.—A correspondent of the *English Mechanic*, who claims to have had great experience in artificial incubation, and who states that he has traveled over the continent of Europe and in Egypt, to ascertain practical facts in regard to the subject, asserts that the temperature required to hatch eggs should vary according to the thickness of the shells. He says the highest success is only to be reached by particular attention to this point. For thick shells he gives an average heat of 110° as the proper temperature for hatching. For medium shells, 100°, and for thin shells, 95°. Experiments of our own in artificial incubation, show that the latter temperature is several degrees too low for the eggs of any kind of fowl reared in this country. Various authorities give the temperature of the blood of a chicken as 111°. During the act of incubation, the temperature of the blood of fowls is somewhat raised, the animal becoming feverish. The temperature of eggs, during the natural process of hatching, is maintained probably quite up to that of the normal temperature of the blood of the incubating fowl. We have never succeeded in artificially hatching eggs at an average temperature below 110° and we believe that an attempt to hatch even the thinnest shelled eggs with an average temperature of 95° will fail.—*Artisan.*

PRESEAVING IRON AND STEEL SURFACES FROM RUST.—A varnish which will effectually prevent iron and steel surfaces from rusting may be made of the following ingredients: Resin, 120 parts; sandarac, 180 parts; gum lac, 50 parts. These should be subjected to a regular heat until melted and thoroughly incorporated, when 120 parts of turpentine are added, and subsequently, after further heating, 180 parts rectified alcohol. After careful filtration, the varnish should be put up in bottles and kept tightly corked until used. It will keep bright iron and steel rods from rust under almost all conditions.

ADHESIVE PLASTER.—According to Otto Facilities, adhesive plaster, which has become brittle by age, and has lost its adhesive qualities, may be rendered adhesive again by coating it with oil of turpentine, by means of a sponge, and leaving it exposed for a day.

Encaustic Colors.

Encaustic colors are the various metallic oxides. When more than one substance is used for coloring, the proportions must be varied to suit the tint required. For violet, use iron or manganese with soda; for purple, chloride of gold with tin and chloride of silver; for black, iron, manganese, uranium, and iridium; for blue, cobalt, carbonate of cobalt, small or silicate of cobalt. Zinc will brighten blue colors. For indigo, use the materials employed for both violet and blue; for turquoise, use copper with soda, or cobalt with zinc and soda phosphate; green may be obtained with copper, either with or without antimony, or by chrome with cobalt; for bronze green, use nickel. Zinc, or carbonate of zinc, will brighten this color. For olive green, use nickel with cobalt; for yellow, use antimony with potash, titanium, chromate of lead, and chromate of barytes. Zinc will brighten this yellow. For buff, use the materials for yellow, with iron, sepia, sienna, ochre, and amber; for orange, use uranium, or the sulphide of antimony with iron; for red, use iron, chromate of iron, sulphate, copper, and ochre; for carmine, chloride of silver; for pink, iron and chrome, with potash; for brown, use iron, chromate of iron, manganese, with or without cobalt, ochre, and hammer clunder; for gray, use iron, cobalt, iridium, platinum, titanium; for white, white clay and five per cent. tin oxide. The coloring oxides are used in quantities of from five to ten per cent., sometimes from fifteen to twenty per cent. No definite rule can be given for quantity. Some of these oxides act as fluxes, and great skill must be used in their employment, in order to prevent the melting of the tile.—*Artisan.*

STRENGTH OF BUILDING MATERIAL.—Experiments are sometimes made in regard to the power of stones of different kinds to resist compression, by cutting one cubic inch off each, placing it between two steel plates, and charging it with increasing weight till crushed. For convenience sake, this weight is applied by means of a lever, so as to obviate the necessity of actually handling the hundreds and thousands of pounds—one or more sliding weights on a strong beam being sufficient for these experiments. The results, taken from an exchange, are indicated in the following table, in which the number of pounds is that of which the substance could bear the pressure, while it was crushed by the addition of more:

Name of Stone.	Weight applied in Pounds.
Inferior Pale Brick.....	2,000
Common Good Brick.....	4,000
Hard Brick.....	5,500
Pressed Philadelphia Brick.....	5,500
New England Granite.....	11,200
Italian Marble.....	12,800

GLUE MELTING.—Break the glue into small pieces, and soak from 12 to 24 hours in cold water; put the glue in the glue pot, fill the outer vessel with water, and apply heat. For ordinary purposes it should run freely, and be of the consistency of thin treacle. The hotter glue is, the more force it will exert in keeping the two parts glued together. In all large and long joints the glue should be applied immediately after boiling. Glue loses much of its strength by being often melted; that glue, therefore, which is newly made, is much preferable to that which has been used. When done with, add some of the boiling water from the outer vessel to the glue, so as to make it too thin for use. Put it away till wanted again, and by the time the water in the outer vessel is boiled, the glue in the inner is ready melted, and the proper thickness for use. Powdered chalk, brick dust or sawdust, added to glue, will make it hold it with more than ordinary firmness.

FIRE AND WATER-PROOF PAINT.—Slack stone-lime, by putting into a tub, covered to keep in the steam; when slackened pass the powder through a fine sieve, and to every six quarts add a quart of rock salt and a gallon of water; then boil and skim clear; to every five gallons of the liquid add pulverized alum one pound, pulverized copperas, half pound, and stir slowly; add powdered potash, three-quarters of a pound, then very fine sand or hickory ashes, four pounds; then use any coloring matter desired, and apply with a brush. It looks better than any ordinary paint, and is durable as slate; will stop small leaks in roofs, prevent moss from growing thereon, make it incombustible, and render brick impervious to water.—*Boston Cultivator.*

TO KEEP AIR FROM WINE OR CIDER DURING FERMENTATION.—The *Boston Journal of Chemistry* says, that a tin tube made like a siphon, driven into the vent of a barrel of wine or cider, and the other end inserted into a vial of water, will prevent the air from entering the barrel, while the gas escapes through the water. Make the barrel otherwise tight. When the cider or wine is done working, the water in the bottle will cease bubbling. It requires no filling up, as there is no loss.

ANTI BOILER INCORUSTATION.—As a preventive of boiler incrustations, milk of lime and baric chloride are recommended; the former for the precipitation of the lime bicarbonate, the latter for that of the gypsum, before the water is run into the boiler.

A RED INK WHICH RESISTS THE ACTION OF MOST CHEMICALS.—This ink is a solution of carmine in soluble glass, and must be kept in a bottle, with a well oiled cork.—*Sc. Am.*

GOOD HEALTH.

Health from Shakespeare.

How quickly nature falls into revolt
When gold becomes her object.
For this the foolish over-careful fathers
Have broke their sleep with thoughts, their brains
With care.
Their bones with industry.—*Henry IV., 2nd part.*

Will fortune never come with both hands full,
But write her fair words still in foulest letters?
She either gives a stomach and no food—
Such are the poor in health—or else a feast
And takes away the stomach—such are the rich
That have abundance and enjoy it not.
I swear 'tis better to be lowly born,
And range with humble livers in content,
Than be perched up in a glistening grief,
And wear a golden sorrow.—*Henry VIII.*

Foul Air.

Dr. Brigham writes, in the *Herald of Health*: Why need we seek illustrations of bad ventilation when the complaint is so universal, and no place seems to be exempt? What dwelling-house has a perfectly satisfactory air, even where no nuisance can be detected on the premises, and no expense has been spared in enticing into it the breezes of heaven. Where is the workshop in which the pleasure of easy breathing moves the artisan to perpetual song in his toil? Where is the office in which the lawyer finds that the air makes dry briefs spirited, and turns to a pastime the search for authorities; or in which the doctor does not inhale a draught which is only less bitter than his powders and his pills? Where are the bed-chambers in which the dreams are naturally of Araby the blest, or in which the tired brain is left by the air to sleep in Elysium?

Perhaps this complaint about foul air is extravagant, and more ado is made about it than the facts will warrant. Our fathers were not so sensitive, and they kept health in houses where no direct provision was made for ventilation. Have we not grown morbid about a matter which is really of minor importance? Is it not really a misfortune that air is so readily analyzed, and that there is so much prying into its quality, to detect a few grains more or less of intrusive plague? Are we any happier or sounder in body because we know exactly the proportion of oxygen and nitrogen and carbon and water that ought to be in the normal air, and can test it and weigh it? Were not ignorance bliss, rather than this perpetual fret about what seems beyond help? Not a few impatient souls have come to hate this persistent alarm about an evil which seems to have become an excuse for grater evils, and to unsettle the foundations of morality. Are we not told that the sins of men come from the bad air which they breathe, and that crimes are the product of atmospheric impurities? Is not the carbon of the cellars and the attics made responsible for the larcenies and murders upon the highway? "For heaven's sake," they say, "stop this tirade about ventilation and bad air; submit to the inevitable, and let us have peace!"

But science is inexorable. We have discovered the mischief, and in spite of this plea of passive submission science will not be silent until the evil is corrected and the remedy is shown. We shall fight it out on this line, if it takes all the rest of the century to finish the fight. We shall agitate and agitate, until the foul vapors are shaken out and away from the abodes of Christian women and men. We shall try experiments, even if a hundred more shall fail, until "achieved is the glorious work." We shall work on, hoping against hope, it may be, until man becomes a successful ruler of the earth because he has fairly dethroned Satan, and become "Prince of the powers of the air." We shall expose the causes of bad air, and plead and threaten until they are set aside. We shall not let the world live in its delusion, or die in its sin; but shall cry aloud and spare not. There is no discharge in this war for any one who has sworn to protect the public health, and to watch in its behalf.

1. The first source of impurity in the air is the carbon given out in the process of breathing. Each breath that we draw helps to spoil the next breath that we shall draw, if we are held in a room where the air is confined. Of course this cause is more efficient as the number of those who breathe is greater. The air is ruined more rapidly in a room where a dozen are pouring out carbon from their lungs than where only a single pair of lungs are at work; more rapidly in a room where a thousand are crowded together than where there are only fifty or a hundred. The poison there is speedy in its working, and we feel it in nerve and vein. But it is not less real in the chamber where we sleep or the library where we read, because its influence is so silent and we take no heed of it. While we draw in the breath of life we are all the time throwing out the breath of death.

2. *Exhalations from bodies* are a second source from which poison comes into the air. The healthiest body, full of bounding life, sends continually into the atmosphere around it the seeds of disease. The emanations from any organized animal frame put into the air something foreign to its purity. Plants, indeed, purify the air by what they absorb and by what they give out; but no one pretends that animals purify the air by their bodies, whether they are men or swine. Caliban in his den, rolled in his unwashed rug, does not vitiate the air more surely than Brummel in his boudoir, anointed and perfumed. Perspiration assists respiration in the distribution of carbon, and the result of a perspiring crowd

in a ball-room or a church is not radically different from the result in a ginshop, or a hovel, where animal heat infuses the air with its microscopic deadly germs. Even the harmless, necessary cat, clearest of all household pets, does evil to the air which can be appreciated. And the dear love of a spaniel or a poodle, washed and combed, and ringed with a pink ribbon, vitiates the air of the room while he lies upon his cushion.

3. Next to these two causes of impurity in the air, from which we never can get away, we may place the decomposition of waste and refuse, from the influence of which very few homes of men are free. From the store-room and the pantry, from the kitchen and the back yard, from vegetables and fruits in decay, from meats hung up economically, from garments rotting in dampness, from mould upon the walls, from the hanks and parings and the ash-hops, what foul aroma rises before they melt and crumble into common dust! The most diligence cannot quite remove this source of pollution. No sewerage comes so often, or does his work so thoroughly, that he carries off every kind of decaying fibre. Some fungus will stay in the most jealously cleaned habitation. Where there is life and moisture, the rock will have always its moss and its lichens. Is there not paste upon the plaster? Does not the steam of the roasting and broiling come charged with effluvia, which may be grateful to the nostrils yet baseful in the residue of corruption? Friendship may live while the pot boils, according to the Latin proverb: "*Fervet olla vivit amicitia*," but when the pot has done boiling, the latter emanations are unfriendly to health and comfort.

4. Of course dust has a large share in loading the air with foreign substance dust in many kinds, room dust, street dust and field dust, dust which hides in carpets and curtains, dust which is on the hearth and the window-sill and the cornice, dust which is palpable and vexes the nostrils, and dust which we only detect as it floats in the rays of sunlight. We have not to wait for death in order to return to dust; we never get away from it, even if we dwell by the lake and remote from the highway. Very few of the human race breathe an air in which there is no dust. It can only be in the region of ice fields and polar snows. Even in mid-ocean dust flies in the air. Most of us live in an atmosphere thick with dust, rising from the pavement, rolling from the roadway, sifting through all crannies of the house, and borne in the garments wherever we go. Dust accompanies our pleasures; it is raised by the flying feet, and on the race-course we can call to mind the wall of Ezekiel. "By reason of the abundance of his horses their dust shall cover thee."

5. *Sewers and stagnant pools* are another fruitful source of pollution in the air. The best system of sewerage, carefully carried under the ground, with pipes impervious and cemented, cannot keep in all the pestilent vapors. Foul water, in its flow and its evaporation, inevitably dissolves into foul air. The conveniences within the house becomes its plague. How shall the air of a city be kept pure when running rivers of filth are drawn under all its streets, to poison the water of the natural river into which they flow? Shall all the odors of Farina, genuine and spurious, clean the air of Cologne, while the river Rhine catches a flow not strained, but in no other respect like the quality of mercy?

6. *Miasma* from decaying vegetation, from marshes and alluvial soil, is another curse from which, in many localities, the air cannot escape. The deadly blight goes beyond the spot of its origin and spreads far, in spite of all effort to keep it back. It comes from the meadow up to the lawn, and from the lawn into the house. We breathe it in the mists of the evening and the mists of the morning, and the August air, which seems so refreshing and cool, is only malaria, which mortals ought to dread.

7. *Combustion*, too, in the methods which men employ it, destroys the air by the gases which it generates. Through the cast iron furnaces and red hot stoves, carbonic oxide finds its way into the current, and fills the house with a stupefying influence. Factory chimneys and house chimneys in the cities belch forth their smoke and send it through the air in sooty rain. Shall we expect pure air where the curling fumes of a copper mill or a chemical factory flock the sky?

8. And then how many necessary nuisances disperse their odors in the haunts of civilized men! Glue factories, bone boiling works, soap works, tripe works, slaughter houses, breweries, tanneries, petroleum refineries, fish spread upon the land, charcoal pits, etc., combine to poison the air.

NITRATE OF SILVER REMOVED BY IODIDE OF POTASSIUM.—Dr. L. P. Yandell, Jr., reports two cases, both young merchants, who had been unsuccessfully treated for epilepsy by urate of silver, in their youth; and whose skins were badly discolored by the remedy. Both contracted syphilis, and for tertiary symptoms were given iodide of potassium from ten to sixty grain doses, thrice daily, for a number of months. The color of the skin gradually improved, until in one no trace of the staining remained, and in the other but a faint shadow of it. He goes on to state that mercurial vapor-baths were administered during much of the time, which, by the diaphoresis excited, probably aided the action of the iodide; and suggests that in the treatment of urate of silver discoloration, the vapor-bath should be used in connection with the iodide of potassium.

TABLE OF CONTENTS.

GENERAL EDITORIALS.—Extension Steps for Railway Cars, 257; A Novel Wire Fence, 262. **Brakes in England, 257.** **A Novel Wire Fence, 262.** **Montana's Gold; The Negley Amendment; Mining Accidents; The Mining Bill and Negley Amendment, 264.** **Eureka District; The Chase Pipe Cutting and Threading Machine; A Challenge, 265.** **The Sovereigns of Industry; The Improved Bail for the Improved Spout of Headers; Patents and Inventions, 268.** **ILLUSTRATIONS.**—Albert's Extension Steps for Railway Cars, 257; A Novel Wire Fence, 262. **THE CHASE PIPE CUTTING AND THREADING MACHINE, 265.** **CORRESPONDENCE.**—Notes of Travel in Colorado, 268. **SCIENTIFIC PROGRESS.**—Gun-Cotton: The Heat of the Moon; Microscopic Crystals in Plants; The Effect of Heat on Textile Fabrics; Qualitative Analysis of Benzene, Extracting Chlorine, 259. **MECHANICAL PROGRESS.**—The Pneumatic Discharge; High-Pressure Filter; Pointing Wire; Artificial Marble; Shoes by Steam; An Efficient Battery; Newbold's Improved Furnace Bars, 257. **MINING STOCK MARKET.**—Table of Daily Sales and Prices and Comparative Prices for the Week; Notices of Assessments; Meetings and Dividends; Review of Stock Market for the Week, 260. **MINING SUMMARY.**—from various counties in California, Nevada, Arizona, Montana, Oregon, and Washington, 261. **USEFUL INFORMATION.**—The Waste of Oil; Temperature Required to Hatch Eggs; Preserving Iron and Steel Surfaces from Rust; Adhesive, Plaster; Encaustic Colors; Strength of Building Material; Glue Melting; Fire and Water-Proof Paint; To Keep Air from Wine or Cider During Fermentation; Anti-Boiler Incrustation; A Red Oak which Resists the Acids, 263. **GOOD HEALTH.**—Health from Shakespeare; Tonic Air; Nitrate of Silver Removed by Iodide of Potassium, 263. **MISCELLANEOUS.**—Lower California Placer Mines; The Mines near Cambria; Sticken River Mines; Mining Sale; Quicksilver, 258; Agricultural Implements; Valuable Advertisements; Coal Ashes; Hydraulic Mines; Coal in Amador, 262; Nickel; Drilled Mining in Gold Canon; Mines in Queensland; Salt Manufacture; Telegraphic Progress; The Haywood Coal Interest; The St. Gotthard Tunnel; The Onyanka Case; South Australian Mines, 266. **Rabbit Culture, 269.**

MONTANA'S GOLD.—In a debate in Congress, relative to the establishment of assay offices at Helena (Montana), St. Louis (Missouri), and Chicago (Illinois), Delegate McGinnis made a strong appeal for its passage; and, after describing the risks and dangers of transporting the treasure of Montana and the exaction and heavy charges to which his constituents were subjected by gold-dust brokers and private assay offices, made the following interesting statement: "I would say to the House that the Territory of Montana, although one most isolated, is and has been our greatest gold-producing Territory. It has been organized 10 years, and in those 10 years it has produced \$160,000,000 of gold and silver bullion; more than a million a month, and nearly enough to pay one-half of your greenbacks; and I believe that in the ten years to come it will produce enough to pay the rest. By the laws of the United States, and more than that, by the Constitution of the United States, every man who possesses or produces bullion is entitled to have it coined at a reasonable cost. But on all that magnificent contribution to the nation's wealth, the miners of Montana have had to pay from four to five per cent. to get their bullion to the mint at Philadelphia, or the Market at Wall street, New York. They have been obliged to pay express companies 2½ per cent. to get their gold to the mint, and often have had to pay in addition quite as much to get their greenbacks back in exchange, and this, although they are as fairly entitled as any other citizens under the Constitution of the United States to reasonable facilities for converting that gold into coin."

CROWN POINT.—This splendid mine, still "keeps up its tick." The receipts for March were \$738,000; expenses, \$323,000; leaving a net surplus of \$415,000, of which \$400,000 was paid in dividends. The mine is still producing at the rate of 100,000 lbs. of gold per month.

THE MINING EXCITEMENT AT SILVER CITY, NEX.—Large hoisting works and tailing flumes are being constructed at the mines, and not an idle man is to be found in the vicinity.

THE NEW MACHINERY.—which is to be used for the incline of the Crown Point mine, will be the most powerful of its class in the United States.

The Negley Amendment.

The appointment of Senator Jones, vice Senator Chandler, resigned, on the Committee of Mines and Mining, in Congress, just at this time, looks, in view of Senator Jones' experience in this line, like a proper act. Still there are some, who, perhaps, will find fault with the appointment. It does appear rather a questionable proceeding for a man so largely interested as he is, to sit in judgment on the Amendments to the Mining Law, which will affect his interests so greatly. He may be above personal considerations on the subject, but the public have of late come to the conclusion that all people in high places under the Government will bear watching. Senator Jones is pretty well posted in mining matters; that, no one will deny, but is he going to watch out for the interests of the common miner as much as for that of the capitalist? There is something going on in Congress which miners do not understand. Just at a time when highly important bills and amendments are being considered, with strong influences on both sides, changes take place which may portend more than they appear to.

Commissioner Drummond, of the Land Office, an efficient and honest man, resigns shortly after having expressed a decided opinion on the subject of one of these bills. Senator Jones, who is heavily interested in the result of the Negley Amendment, is appointed on the Committee of Mines and Mining, in place of Chandler. Senator Jones has created an excitement, by a surprising speech, and proven that he can talk when he wants to. Could he not have served the mining interests as well out of, as in that committee? If his advice was wanted, it could have easily been procured. We do not believe that his acceptance of the position will be looked upon with favor by any of the miners, except the rich owners of the productive mines on the Comstock. And, looking at it from the view of those who own ledges off the immediate line of the Comstock proper, their reasoning seems very plausible. They say that Senator Jones owns the Crown Point mine. That he, like all the large companies, is working some distance to the eastward of his original location. The Crown Point, like the other productive mines, must define its boundaries within six months under the Negley amendment. The Crown Point does not want to define its boundaries any more than any of the other big claims. The poor men say that under the present system and laws, the rich men have the best of it. The rich men will not patent their claims nor allow the poor ones to do so. If a claim off to the eastward starts in to get a patent, one of the big ones near by enters a protest, on any ground convenient, and by this means gets a "stay of proceedings." Then under the law the case is brought into the local courts, which we all know do not bear the best of reputations. When once in court, and especially in some of the Nevada courts, it does not take much shrewdness to guess who will get a verdict—the rich or poor man.

Now if the Negley Amendment is adopted it will change this method. The productive mines only are compelled to procure a patent, and the others must render annual accounts, and when they become productive, they must patent their land also. The productive mines do not want patents because they must define their boundaries, and the burden of proof rests with them. If they are working over their boundaries, and following other leads, than dips, spurs or angles of the one they originally located, and that under other men's ground, have they got any right to do so? If they have, they will be let alone? If they have not, let the proper owners have it. It does not make any difference to the country at large who owns the productive mines, so long as they are productive ones; works will be erected and men employed just the same. But these rich companies will not define their boundaries, and while working their own mines, will not permit others near by to be patented for fear of losing ground, which many of them do not believe they really own.

Many of these claim owners do not like the Negley Amendment because it provides that the Suto Tunnel royalty must be paid anyhow, whether this amendment is passed or not. And if many of these mines found themselves in early days to do certain things, why should they now seek to crawl out of it to the injury of others, because the others have the best of the bargain? They ought to have looked out for that in the first place. If the Suto Tunnel Company had certain rights and franchises, and undertook an expensive operation because they had them, they should be protected in these rights. Leaving aside all considerations as to whether the tunnel will be beneficial or not, if the tunnel owners have spent large sums of money, on the strength of rights given to them by the highest tribunal in the nation, they ought now to be protected in these rights. If Suto had bound himself to drain and ventilate the mines free of charge, and only claimed the blind lodes he struck, it is pretty certain that the companies would compel him to finish his tunnel.

Now the question with the common miner in relation to the Negley Amendment, etc., is whether there is any great wrong being done in compelling the productive mines to define their boundaries, once for all, so that other people can know where they are. Because these

men have located on a ledge and sunk deep shafts and run lengthy drifts, does it give them the right to everything underground for a mile or two each way, whether on the original ledge or not? Is Senator Jones, who owns one of these productive mines, the man to sit in judgment as to whether the amendment is a proper one or not? Is his opinion an unbiased one? Will the poor man have as good a chance as the rich one? Is it better to make these miners define their boundaries now, or wait until they have worked out all the ore—their own and that belonging to others? Is there any practical hardship in making ten or a dozen mines spend \$1,000 each in getting a patent? It is not the money they care for, but they do not want to define their boundaries.

We give these views as the views of those miners owning ground to the eastward of the original Comstock. If the big miners believe in the "one ledge theory," and can get mining experts to corroborate their views, they need not fear the new amendment. If there is more than one ledge, these companies haven't any right to more than they located, and others ought to have a chance. The amendment only applies to the Comstock, and only to the productive mines; and as their owners only want to fight it, there seems to be a very good reason for poor men to think that it will benefit them more than the rich.

Mining Accidents.

The Eureka Sentinel, of the 16th, mentions an accident which occurred in the Dunderberg mine, on the Prospect mountain, whereby a man named John Buckingham met with serious injury. He was engaged in blasting in the lower mine, and having placed two cartridges in proper position, retired to a safe distance until the explosion had taken place, which shortly followed; but, it appears, that one of the cartridges had performed its work; the other, for some unexplained cause, had not exploded, and just as Buckingham was about proceeding to his work, it went off, the flying rocks striking him with full force about the head and face, cutting him badly. The most serious wounds are a fracture of the skull and a deep cut on the forehead. His hair and eyebrows were badly singed by the burning powder, and he had a very narrow escape from losing his eyesight.

On the 16th inst., at Dutch Flat, Placer county, an explosion occurred in the Cedar Creek Mining Company's tunnel, which resulted in the death of McOlive, a laborer. Six or eight cartridges had been fired, and the workmen were engaged taking out the loose rock, when the deceased struck an unexploded cartridge with his pick, which exploded the cartridge, mauling the lower part of his body in a horrible manner, from the effects of which he died in about half an hour. No other persons were seriously hurt.

VANCE NELSON, a miner employed in the Sheba mine, at Star District, Nevada, had the first joint of the little finger of the right hand cut off, last week, by a falling rock. He was working in a raising stope, and soon after letting off a blast returned to commence work. As he placed his hand on a heavy timber to climb up into the stope a quantity of rock that had been loosened by the blast fell upon him, the largest piece, weighing about forty pounds, catching his finger against the timber cut off the joint.

A PROFITABLE MINER.—The Van, a prominent English miner, has paid more dividends than mines generally do. Since they began work, the ore sold amounted to 25,565 tons of lead, and 5,320 tons of blende, for which the company received a total of \$371,466. The company began work in February, 1869, and these figures include the last sale made on the 12th of March last. From the proceeds of these sales, the directors had divided, up to the end of 1873, a sum of \$167,250 in dividends, or very nearly the capital of the company three times told.

THE MONTEREY AND SALINAS NARROW GAUGE RAILROAD COMPANY broke ground this week about 10 miles from Monterey. The Salinas valley, which was formerly devoted to stock-raising, is now one of the most extensive grain-producing sections of the State; and this railroad will transport grain, etc., to Monterey, to be shipped by sea, instead of by a longer route by rail. The idea of a railroad in Monterey seems a strange one, as it is a sleepy, Spanish town, which, though one of the oldest, is one of the most backward in California.

STICKEN.—The messenger, Sylvester, brought down to Fort Wrangel late news from the Sticken mines. He informs the Victoria Standard that the weather was extremely cold, and it is impossible to prospect. The opinion formed of the country by the miners in general is favorable. There is no doubt whatever of the richness of the mines, as reported after last year's prospect, but one year's further prospecting is necessary. Found 250 men in the mines, and met 300 on the way, bound in.

COMMISSIONER DRUMMOND.—In consequence of the inadequate salary allowed him, Hon. Willis Drummond, Commissioner of the General Land Office, has resigned, and will retire from office on the 1st of May. It is reported that ex-Congressman Burdett will probably be appointed to succeed Mr. Drummond.

Work was commenced this week on the extension of the railroad south from Delano.

The Mining Bill and Negley Amendment.

We give below the full and correct text of the Mining Bill with Negley's Amendment, which was on the 2d inst. referred to the Committee on Mines and Mining, with the Amendment (Negley's) of the House of Representatives viz: Strike out the second section of the Bill as passed the Senate, and insert in lieu thereof the latter part, which is printed in smaller type.

AN ACT supplemental to the Act entitled, "An Act to promote the development of the mining resources of the United States," approved May tenth, eighteen hundred and seventy-two.

Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled, That where applications for patents for mining claims have been filed in the proper district land office, and legal notice thereof given without the appearance of an adverse claimant, and in which cases no further proceedings have been had for the purpose of perfecting title, such applicants shall make final proof and payment on said claims within one year from the date of the passage of this act; and in cases of like applications for patents hereafter filed, the applicants shall, in the absence of an adverse claim during the notice, make said final proof and payment within one year from the date of filing such application, in default of which the proceedings for patent so had by such applicants shall be considered void and without effect.

Sec. 2. [That all affidavits required to be made under this act, the act to which this is supplemental, or the act to which said act is amendatory, may be verified before any officer authorized to administer oaths, and all testimony and proofs may be taken before any such officer, and, when duly certified by the officer taking the same, shall have the same force and effect as if taken before the register and the receiver of the district land office.] Provided, that when such affidavits or proofs are taken at any place other than within the land district, it shall be by the clerk of any court of record in the United States.

That all ex parte affidavits and proofs required by law to be made before the local land offices in mining or preemption cases may be taken before any officer authorized to administer oaths in the land district where the claim may be situated, or out of such district, before the judge or clerk of any court of record, and in all cases of contest the testimony or proofs required may be taken before any clerk of a court of record in the land district where the claim may be situated, on personal notice of at least ten days to the opposing party; or, if said opposing party cannot be found, then by publication of at least once a week for thirty days, in a newspaper, to be designated by the register of the land office as published nearest to the location of such land; and the register shall require proof that such notice has been given, and such affidavits and proofs, when filed with the register, shall have the same effect as if taken before those officers. Provided, that in such contest cases, the testimony of a witness residing out of the land district may be taken in the county of his residence, in the mode herein prescribed. Effect shall be given to this act by regulations to be prescribed by the Commissioner of the General Land Office, and no regulation or order, or anything contained therein shall affect or make void any patents granted by applicants for claims on mines on the Comstock Lode, in the State of Nevada, nor shall it be construed to repeal, impair, or in any way affect the provisions of the act granting to A. Suto the right of way and other privileges, to aid in the construction of the Suto Tunnel, and exploring tunnel to the Comstock Lode, in the State of Nevada, approved July twenty-fifth, eighteen hundred and sixty-six. And provided further, That all persons, companies, or corporations owning claims or mines on said Comstock Lode shall make application for patents within six months from the date of the passage of this act, and in the absence of a bona fide adverse claim during the notice make final proof and payment, and file an abstract of the same in the same manner as hereinafter provided within twelve months from the date of filing such application; or, if already filed, from the date of the passage of this act; and in default thereof, or in default of filing with the register of the land office at Carson city, in all cases where patents have already been issued, an acknowledgment of the receipt of such patent, subject to the conditions therein contained, within twelve months from the passage of this act, such claims or mines shall be open to relocation by other parties in the same manner as if no location of the same had ever been made, always subject, however, to the conditions of the Suto Tunnel act approved July twenty-fifth, eighteen hundred and sixty-six. And provided further, That unproductive mines located on the Comstock Lode shall not be required to secure patents until the same shall become productive; but it shall be the duty of the owners or claimants of such mines to make a written report of the progress of development in their mines to the register of the nearest land office at the expiration of each year.

Passed the Senate February 16, 1874.

Attest: GEO. C. GORHAM, Sec'y.

LEAD contains many impurities, such as sulphur, iron, tin, antimony and copper. Impure lead is known by being whiter and less soft than the pure article, which readily stains the hands, linen, etc. The impurities commonly found are injurious for technical applications, especially white lead making. Pure lead melts at 330 deg. to 335 deg. It is brittle a little below the melting point, and volatile in closed vessels at a white heat.

PAGE & PANAMA.—The trouble between the stockholders of the Page & Panama mine, which involved half a dozen charges and cross charges of assault and battery, malicious mischief, vulgar language, etc., was adjourned this week. Mr. Falk, representing one of the antagonistic elements, became possessed of enough stock to elect himself President, which seems to have removed all cause of conflict.

The recent finding of ruins of a fortification and tower, by Lieutenant Ward's command, east of Florence, on the Gila river, is another proof that all of Arizona was once inhabited by a very superior race of beings to those found by the first white explorers.

Eureka District.

[From our regular correspondent.]

The Eureka Mining District was organized sometime in the summer of 1865, yet it was not brought prominently before the public as a mining center till early in the spring of 1870. It is situated among the low range of scrubby hills running northeasterly and easterly from Prospect Mountain, which is the main range of the district, having its course almost due north and south. There are many valuable mines located on the eastern slopes of this range, whose altitude can not be less than 8,000 feet above the level of salt water. The district proper embraces an area of something like four square miles. It is, however, bounded 18 miles on the northeast by Diamond Mountain District; 12 miles southeast by Pinto; 14 miles same direction by New Mark; 7 miles south by Secret Cañon District; and 12 miles to the west by Spring Valley District, which, with the others just enumerated, are all tributary to and dependent upon Eureka for their supplies, as are the districts south of it. The population of the town and district numbers about 6,000 souls, drawn hither chiefly by the prospect of gain which the wealth and great mineral resources of the district held, and still holds out to them, and the others that are sure to make it their homes in the future. Seldom or never were there brighter prospects spread before any of the mining camps of Eastern Nevada, or more real signs of permanency and prosperity before itself, than those and these that are now dawning upon Eureka.

The Town

It is situated in about 38°40' of north latitude, and is built in a long, low cañon, at a point where it opens out in the shape of an ellipse; betwixt the hills that inclose it on the east and west. It is reached by stage, distance of 80 miles from the Palisade station, on the Central-Pacific line, and is distant from San Francisco, probably 460 miles as the crow flies; through by rail, via Palisade, it is something over 600 miles. The general features of the town and surrounding country do not differ materially from those of other sections. There is a sameness about mining towns, particularly about the towns of this State, that can be found nowhere else on the coast, and a description of one would go far to cover all the others. The style, dimensions, appearance and architectural finish of the houses, stores, etc., are about equal. Here we have the inevitable main street, found in every mountain burg, of any pretensions to metropolitan importance. It is a long, straggling thoroughfare, running in a straight line midway betwixt the sides of the ellipse, on each side of whose length, for a half mile or more, are built stores, saloons, restaurants, hotels, lodging-houses, etc. The Richmond and Consolidated furnaces occupy the extreme and opposite ends of the town, the former on the south and the latter on the north, while the Silver West, Jackson, Ruby, Consolidated and Hoosac furnaces are ranged on the declivities of the hills, bordering the west side of the town, which is adorned by many elegant and substantial buildings of wood, brick and a kind of soft, white sand-stone, found in abundance at a convenient distance. Being very soft when first quarried, it is easily dressed and prepared for buildings, and hardens when exposed for any length of time to the air and sun.

The county buildings consist of a jail, a county hospital, a commodious public school house and a court house, in which latter building are arranged the county offices, such as the Clerk's, the Treasurer's, Assessor's, District Attorney's, Surveyor's, Auditor's and County Recorder's office; while the Sheriff and his Deputy have their office in the strong house of the county, over which they preside. The financial affairs of the county, which is yet in its infancy, though it is making vigorous strides toward manhood, are in a very healthy condition, and are ably and judiciously managed by a trimvirate Board of County Commissioners, who hold five sessions a month, presided over by D. H. Hall, of the International Hotel. They receive for their services a pitiable monthly stipend of \$50, and being public servants liable to public censure, are often grossly and outrageously abused for the real or imaginary wrongs they commit; and my opinion is, that the imaginary offences, largely preponderate over the real ones. The dear public is, however, a capricious creature of many impulses, some warm and generous, some cold and selfish, while its very fickleness in matters of the gravest import renders it about as hard to be understood in the various moods and tempers as the caprices of our ancient friend, Lindley Murray, used to be in the days of "auld lang syne," when the hirc and rule helped to indicate the principles they covered, and when the village pedagogue held undivided sway over the minds and senses; for

"There in his noisy mansion, skilled to rule,
The village master taught his little school."
The inculcation of religious and moral ethics

is a thing too that is neither forgotten or neglected as it might be supposed it would be in a mixed and feverish community, such as ours is, and such too as usually constitutes an inland mountain district far removed from the civilizing and refining influences that are found to prevail in less isolated places. Nor do we find that educational facilities are wanting in our midst, for our citizens have manifested a praiseworthy concern in providing suitable schools and competent teachers to mould the plastic minds of their children.

"The education forms the common mind.
Just as the twig is bent the tree's inclined."

Are maxims whose truths are well known and appreciated in our time, and happily too in our country. Intelligence and morality may not always journey together in the same boat, 'tis true, but the first offers of powerful incentive to the growth and perfection of the second, and a combination of the two qualities, when found pervading, animating and directing society, are always sure to bring with them their own reward. There are four places of public worship, which are usually well attended on the Sabbath. You must not infer from this, however, that we are all saints or that we take kindly to the doctrines of the meek and lowly one of Nazareth. These things might be well enough to think of, but somewhat hard to practice in a climate such as ours has been during the past winter. icy blasts will but ill fan the flames of devotion. The human mind is a puzzle to even the keenest metaphysician, and will be so, too, till Gabriel's blast is heard amid the fastnesses of our stern old mountains.

The Weather

Has at last somewhat subsided in its severity. The beautiful vernal season for which we have so long prayed and sighed, has at length burst

THE CHASE PIPE CUTTING AND THREADING MACHINE

over this part of the moral heritage, in the great joy of your correspondent, and divers of his friends. The genial sunshine will now very soon obliterate all traces of the arctic visitations we have just experienced. The snow is fast disappearing from hill and dale, elevated mountain and winding cañon, and the lately impassable approaches to our mines and other places in the vicinity of town are being rapidly put in repair by our two enterprising team owners, Messrs. Davis & Harsh, against the long and busy season they will in a short time inaugurate. Never were there fairer prospects before in Eureka, and never were our people more desirous to take advantage of them than they are at present. Our mining prospects for the coming season are all that the most exacting could desire. Work has been vigorously prosecuted upon many of the mines during the past months, when neither wood nor coal could be hauled to the furnaces. The result of these operations are now everywhere manifest. New strikes are prevalent occurrences in the Richmond, Eureka, Consolidated and K. K. mines. Neither are those of lesser renown behind, for every day we hear of some new and important development. Some notable properties that have long lain idle, to the injury of the district and the disgrace of their owners, are about to have active life and vigor infused into their arteries once more. The Jackson, Phoenix and Adams Hill companies are to recommence work upon their respective mines about the first of the month. There are also many other new improvements and enterprises to be launched here the coming summer, about which I will post the Press in a subsequent letter, when I have more time and greater inclination to write than I have at present.

YUCIPA, a new mining district in San Bernardino county, is bounded on the north by Mill Creek, south by San Jacinto cañon, on the east by Edgar's Creek, and on the west by the San Bernardino mining district.

The Chase Pipe Cutting and Threading Machine.

The machine illustrated on this page is for the purpose of cutting and threading gas and other pipes, and bolts from 1-8 to 2 inches diameter. It is portable, weighs 100 pounds, and occupies a space of about 15x17 inches square. It is constructed in the best manner of cast-steel and malleable iron, the gearing is all cut, and all the parts are interchangeable. It will be found of great importance in gas, steam and all other kinds of pipe fitting, in cutting and threading pipes, making nipples, threading bolts and nuts, and in cutting off bolts to any required length.

In making repairs or fitting up work on ship-board, it would prove to be a useful and economical tool, as it can be readily set up almost anywhere, and the large amount of work it is capable of doing could be performed on board, avoiding the necessity and loss of time in going to and from the shop. It could easily be arranged as a convenient drilling machine.

It operates with ease, and its capacity for doing work is said to be fully equal to that of three men under the old method. It can also be operated by a belt and pulley, and it would be a useful tool in any machine shop.

The machine cuts a thread, makes nipples for all sizes of pipes, from 1/8 up to two inches. It will also cut and thread bolts.

The splitting of pipe is entirely avoided, and a thread can be put on a pipe as large as two inches, with perfect ease. It cuts and

threads and makes nipples for all sizes of pipes, from 1-8 to 2 inches.

The manner of cutting leaves the pipe smooth, with no bevel outside or inside, (to be filed off for putting on the die, or to diminish the diameter), and allows two cent ends to fit closely, thus making a perfectly tight joint. The thread cannot be put on otherwise than straight, and, by its manner of working, dies will wear much longer than as used at present, the chipping of the teeth being avoided.

The machine is strongly made of cast steel, malleable iron and cast iron, the gears all being cut, with every part interchangeable. It weighs 100 pounds, and is made to be a portable machine, working either by hand or power, thus enabling steam and gas fitters to cut and thread pipes, and make their own nipples, where the work is being done, thus preventing the necessity of going to and from the shop.

It will be found very convenient to all steam fitters, gas fitters, machine shops, car shops, steamers, sugar refineries, distilleries, railroad trains using air brakes, and all who have to cut and thread pipe bolts. J. M. Keeler, No. 306 California street, in this city, is agent for the Pacific Coast. The machines cost about \$150, which includes a full set of collars for making nipple.

YELLOWSTONE DIGGINGS.—About 100 men will find employment in Emigrant, Bear and Crevic gulches in the Yellowstone country this summer. On a bar, at the mouth of Bear Gulch, there are two companies engaged in mining. The bar is an immense bed of gravel which all prospects well, and they have an abundance of water.

As the bill providing for the coinage of 20-cent pieces has been favorably reported in the Senate, there may be such a thing as checking the "odd five cent swindle," about which our Eastern brethren grumble so much when they visit us.

A Challenge.

[From the Dayton, (O.) Journal.]

OFFICE OF STOUT, MILLS & TEMPLE,
DAYTON, O., Nov. 17, 1873.

We hereby challenge James L. Leffel & Co., manufacturers of the James Leffel Double Turbine Water Wheel, Springfield, Ohio, to a public scientific test of our respective Turbine wheels. Namely, the James Leffel Double Turbine Wheel and the American turbine. Said wheels are to be tested by competent hydraulic engineers of known ability and experience in testing turbine wheels. Said engineers to be selected by the respective owners of said wheels. Said tests to be made with approved instruments and appliances for determining the power of wheels, and quantity of water. Said wheels to be of ordinary finish, such as is furnished to the trade, and of medium size, from 42 to 64 inches in diameter, and to be tested with one-quarter, three-eighths, one-half, one, one and one-half, three-quarters, seven-eighths and full gates, the part gates to be determined by the quantity of water passing the weir in cubic feet per minute, and not by the amount of gate openings, and the wheel producing the highest average to be declared the successful wheel.

The cost of the defeated wheel are to pay all costs of testing, including in said expenses all traveling expenses of engineers, judges, and one member of each company of the respective owners of said wheels; each party, owners of said wheels, to deposit with the judges five thousand dollars (\$5,000) as security for the faithful fulfillment of the conditions herein named; the entire amount of water used, from 42 to 64 inches in diameter, to be tested with one-quarter, three-eighths, one-half, one, one and one-half, three-quarters, seven-eighths and full gates, the part gates to be determined by the quantity of water passing the weir in cubic feet per minute, and not by the amount of gate openings, and the wheel producing the highest average to be declared the successful wheel.

We will under no condition spend time testing water wheels in competition with any one by grinding grain or driving any kind of machinery, as there are so many contingencies in such tests that it would be impossible to determine the difference with any degree of certainty while the percentage of useful effect could not be determined at all. All who understand testing turbine wheels and have made tests with a view of ascertaining the percentage of useful effect, know that a great deal of careful preparation is required in order to determine the exact amount of water employed and power produced, both of which are indispensable in order to render an intelligent verdict. And if tests were made by any other means except with such instruments and appliances as are required in scientific tests for weighing the power and measuring the water it would be time and money spent to no purpose, and neither the parties interested or the public would be any wiser for the tests having been made.

A series of conflicting certificates and and in confusion. What we demand are thorough scientific tests by competent engineers, from whose decision there can be no appeal. To such tests we challenge James Leffel & Co., of Springfield, Ohio, while, at the same time, the same proposition is open to the world.

STOUT, MILLS & TEMPLE.
The above wheels, built by Stout, Mills & Temple, and which have given such splendid results, may be seen at Treadwell & Co's, in this city, who are agents for their sale, and have a large stock of all sizes on hand.

UNDER CURRENTS are among the mining improvements now being extended in connection with placer claims. An undercurrent flame, costing \$1,000 not infrequently pays \$20 a day during the running season, above expense of cleaning up. Scarcely any attention is given to them while running. We shall give an engraving and description of one of the best styles of under currents in an illustrated paper on placer mining ere long. Hoskins Bros., at Gold Run, use a series of secondary undercurrents, having closer (1/4-inch) gratings. They find that the extra saving of quicksilver pays all the expense, besides the gold which is saved in addition.

NEW INVENTION.—MANUFACTURE OF RUBBER GOODS.—The uses to which Caoutchouc or India Rubber is capable of being applied are almost innumerable, but it is only within a few years past that articles made of this valuable substance have come generally into use. Even now the development which has been effected is nothing to what it is certain to be. The value of Rubber Goods imported and used on the Pacific coast, is about \$2,000,000 annually, of Boots and Shoes alone, there being not less than 8,000 cases sold of a value of \$300,000. With such a large consumption it has been often a matter of wonder that the manufacture has not taken root here, and the fact remains but little to our credit. This stain on our industrial caoutchouc is, however, at last to be wiped out. A company for the manufacture of Rubber Goods is at last being organized by a prominent member of the firm of Buckingham & Heath, Boot and Shoe manufacturers. The capital stock which is being taken by our most prominent capitalists and merchants will be \$1,000,000, and constant employment will be afforded to five hundred hands. We hail the enterprise as one of the most important that has for a long time been undertaken in San Francisco.

THOMAS MCGLEN, inventor of the Eagle furnace, has bonded the Trenton mine, Battle Mountain district, Nevada, for \$45,000. He is to build a furnace on the property immediately.

LIGHTNING creek, B. C., yielded 577 ozs. last week, distributed as follows: Victoria claim, 360 ozs.; Vancouver, 117 ozs.; Van-winkle, 100 ozs.

THIRTY flasks of quicksilver were shipped to San Francisco, on Monday, from the St. John mine, Solano county.

SOME fifty ounces of Snow Shoe Gulch gold were sold at Helena, Montana, on the 2d inst., by miners from the camp, for \$17.75 per ounce.

A DROVE of Chinamen have struck rich gold mines near Baker City, Oregon.

Nickel.

In its review of metals at the Vienna Exposition, *Engineering* gives the following account of nickel:

Since coins of nickel have been introduced in Belgium, Switzerland and Germany as fractional currency, the demand for this metal has greatly increased, and also its price, and this cannot fail to greatly influence all other manufactures in which nickel is used as an alloy with copper and zinc, such as German silver, Argentine, Alfenide, and others. The price, which was about 4s. per pound a couple of years ago, has of late risen to 14s. and 15s., and as the annual production of nickel is but about 500,000 lbs. in Europe, and 200,000 lbs. in America, it is not likely to recede much. England, France, Spain and Italy showed no nickel exhibits at Vienna, although England produces a considerable quantity at Swansea and Birmingham from imported Norwegian and South American ores. Belgium owns nickel works at Val Benoit, near Liege, where Messrs. Levi and Kuntzel extract that metal from regulus, which is made at Varallo, in Piedmont, from magnetic iron pyrites, containing 1.5 to 2.5 of nickel and cobalt.

In the German Section

At the Vienna Exhibition we found nickel exhibited by Fleitmann and Witte, of Iserlohn, in Westphalia, and by the Victoria Nickel Works, of Naumburg, in Saxony. Both seem to smelt principally imported ores or regulus, though the first-named firm seems also to receive part of its ores from some Rhenish and Westphalian iron and lead mines. The once important nickel works of Dillenburg, in Nassau, have been stopped for some years, probably owing to the exhaustion of the ore, which was found at Nanzembach, connected with serpentine and diabase, and contained 2 per cent. to 5 per cent. of nickel, together with some copper. A similar fate seems to have befallen the nickel works of Gladenbach, Grand Duchy of Hesse, where nickel ores were extracted from small lodes in Permian rocks. In the Grand Duchy of Baden nickel ores are found at St. Blasien and Todmoss, these consisting of magnetic iron pyrites with some copper pyrites, and containing 2.5 to 5.5, and even 12 per cent. of metal. The ore is found in hornblende gneiss, and connected with rocks of gabbro and serpentine; it is smelted at St. Blasien in blast furnaces, into a regulus, which is calcined, remelted, and at last refined, so as to yield metal containing 60 to 63 per cent. of nickel, 24 to 27 per cent. of copper, and only 0.3 to 0.5 per cent. of iron. This regulus is sold to the Victoria Works of Naumburg. These works made a very good show of metallic nickel in cubes, and of sulphate of copper, at the Exhibition, and of late they have made themselves independent for raw materials by buying the Sagmyra nickel mines in Sweden. The Mansfeld Copper and Silver Company, and the Goslar Smelting Works, produce likewise a small quantity of alloys of nickel and copper, and of nickel, iron and arsenic. The greatest producers of nickel in Germany, however, are the Saxon Cobalt Company of Oberschlema and Pfannenstiel, near Schneeberg, in the Saxon Erzgebirge. Their annual production is over 10,000 lbs. of pure metal. The clay-slate and mica-schist district, near Schneeberg, Lindenan, Zschornau, and Neustadt, contains over 150 lodes, which yield nickel, cobalt, bismuth and arsenic within a zone of six miles in length and about two miles in width. The mines and works date from 1642, and employ at present over 1,200 miners and smelters, while connected with them are the cobalt and nickel works of Modum in the south of Norway, from whence nickel and cobalt regulus are sent to Saxony for refining. The Saxon Cobalt Company exhibited very good samples of cubes and sheets of nickel.

Looking next to

Austria,

We found, in the Duchy of Salzburg, the Leogang Nickel and Cobalt Company, which produces ores of nickel, cobalt and antimony from irregular metallic deposits in clay slate. The ore is hand-picked, smelted in a blast furnace, and the regulus obtained is refined in a reverberatory furnace for a kind of white metal, or "speiss," containing 28 per cent. of nickel, 14 per cent. of cobalt, 6 to 8 per cent. of copper, and the rest iron, sulphur, and antimony. Flora von Flechner-Gersdorf, of Schladming, in Styria, likewise exhibited nickel ore, consisting of arsenide of nickel from the mines at Zinkwand and Vetter. The mica-schist here contains strata, 2 to 8 fathoms thick, which are impregnated with pyrites and other metallic ores, and intersected by lodes which are metalliferous within these metallic zones or strata, and contain ores of cobalt, nickel, arsenic, fahlerz and others.

From Hungary

We found exhibits by the Kolha Metallic Mine Company, of Lihthen, which produce annually about 300 tons of ores containing from 16 to 20 per cent. of nickel, 4 to 8 per cent. of cobalt, and some copper. The richest ores are sold to Evans, Atkins & Co., of Birmingham, and the poorer stuff smelted for white metal before going to the market. The Zemberg Nickel Company, of Dohschau, in the north of Hungary, produce some 400 to 500 tons of nickel and cobalt ore at their mines Altenberg and Zinnberg. The strata of greywacke there enclose a large bunch of spathic iron ore, viz., carbonate of iron, which contains occasionally

nickel and cobalt ores in contact with the enclosing rock. Underlying the iron ore are dioritic slates, which are traversed by numerous lodes and branch lodes, of which the Maria lode is the principal. They are composed of a black bituminous shale, which contains short, but rich, floors of nickel pyrites, together with fahlerz, arsenical pyrites, spathic iron ore, and ankerite. The richer class of ores contains about 17 per cent. of nickel and 5 per cent. of cobalt, and is sold in England.

In the Swedish Department

We found nickel ore, nickel copper, and metallic nickel, exhibited by G. Berg, from Warby and Westervik. The principal nickel works, however, are at Klefva, in Jonkoping-Lan, and at Sagmyra, in Koppaberg-Lan, where magnetic iron pyrites is found in connection with gabbro and serpentine in metamorphic gneiss. In 1871 their produce was 36,800 lbs. of nickel copper, and 673,000 lbs. of nickel regulus, with about 50 per cent. of nickel and cobalt, 30 per cent. of copper and 8 per cent. of iron. Almost the whole produce is sold to Berlin and Birmingham, where the metal is refined. In Norway there were, in 1870, 10 nickel mines, which employed about 140 men and yielded 88,000 cwt. of raw ore, this consisting of magnetic iron pyrites with 1.5 to 3, sometimes 5 to 7 per cent. of nickel. The largest works are at Skjærdalen and Evje, in Ringerike in the south of Norway, belonging to the Ringerike Nickel Company, and at Bamble, near Kragero on the south coast, belonging to Johan Dahll. From both works we found at Vienna very complete exhibits. The raw ore is first calcined in large heaps, and then smelted in a blast furnace with coke, in order to obtain a regulus with about 15 to 17 per cent. of nickel. This is again roasted in kilns, and smelted for a second regulus with about 30 to 35 per cent. of nickel, which is then remelted with coke in an open hearth under the oxidizing influence of a strong blast, when nearly the whole of the iron and part of the sulphur are oxidized, and an alloy containing 50 to 60 per cent. of nickel, 25 to 30 per cent. of copper, and 24 to 26 per cent. of sulphur is obtained.

In the American Section

We found the very interesting exhibits of Josef Wharton, of Philadelphia, who showed nickel and cobalt ores, including fine samples of fibrous millerite, from Gapmine, in Pennsylvania, which seems to be a neighbor of the celebrated mine La Motte, and which contains a lode five feet thick, yielding ores of nickel, cobalt, copper and lead. There were also samples of nickel regulus and metallic nickel, alloys of half copper and half nickel, and metallic nickel in cubes, shot, and in plates, which latter are employed as electrodes in electro-plating. This process is largely carried out by the Keith Nickel Plating Company of New York, which employs the process of Professor Bottger, of Frankfurt, who was the first to use a solution of sulphate or chloride of nickel-ammonium, from which the coating is deposited upon other metals by the action of a galvanic battery. South America, where rich ores of nickel are found in Peru and Brazil, exhibited nothing at Vienna.

Hydraulic Mining in Cold Canon.

Since the introduction of water in great abundance on the line of the Comstock, several hydraulic enterprises have been projected. It is a well established fact that free gold exists in fair quantities in both Gold and Seven Mile cañons, the former running south from Gold Hill, and the latter east from Virginia City. It was while mining for gold with rockers and other rude appliances that Pete Riley and "Old Virginia" discovered the Ophir croppings, which subsequently led to the discovery of the Comstock lode in the Spring of 1859. Alluding to the organization of a company whose object it was to carry on the business of hydraulic mining in American Flat and along Gold cañon, the *Gold Hill News* of a recent date says:

About the first of January last, an extensive corporation was formed under the name of the Nevada Hydraulic Mining Company, with Judge Heydenfeldt, of San Francisco, as President, H. G. Maynard and A. B. Mitchell, of Gold Hill, and Judge Lewis, T. D. Parkinson and others, of Virginia City, for the purpose of hydraulic mining on American Flat and at Gold Cañon, at convenient intervals between Gold Hill and the town of Dayton, in Lyon county. The first step taken was to locate and secure a title to all the unoccupied surface ground on either side of Gold cañon from its head to its mouth. This done, the next was to obtain a supply of water from the Virginia and Gold Hill Water Company for working purposes, which the completion and successful operation of their new flume now enables them to furnish. Having procured the necessary water, the Hydraulic Company propose shortly to commence the erection of extensive hydraulic works on American Flat, at Silver City, and along the cañon between the latter place and Dayton. It is a well-known fact that the sides of Gold cañon, in many places, and the ravines extending down through American Flat, in early days paid handsomely, and in some places richly, for working, with but a limited supply of water. Good prospects of gold can be obtained on the surface in many places high up on the sides of the cañon, and there seems hardly a doubt that, with a good supply of water, and in the hands of energetic, able men, such as compose this company, the project will not only be made to pay richly, but will add another very important feature to our mining enterprises.

Mines in Queensland.

We extract the following, concerning the mining interests of Queensland, from an English work on Australia and New Zealand:

While the Talgai and Lucky Valley by the Darling Downs, and the Ennoggera, of Brisbane, are in the south, a nest of mines are in Burnett district. Near the Gympie are Kilkivan, Jimna, and Cania mines. Port Curtis had a rush as early as 1857. Rockhampton, the so-called northern capital of Queensland, was established by the miners of Canoona, and is now the center of the mines of Central Queensland. These are the Peak Down, Ridelands, Morinish, Rosewood, Crocodile, Calliope, Cawarral, etc. But the most important auriferous display is in the north. Ravenswood, opened in 1869, is a field of 550 square miles; the township is 100 miles south of Townville Port. Charters Towers, Bronghton, Mount Wyatt, the Pyramids, and Milchester are other northern fields. Rosewood is an alluvial ground. The Cape River gold field is 600 square miles in area. The Gilbert is a new auriferous territory, about 200 miles from Rockingham Bay, towards the Gulf of Carpentaria. Gold has been traced along the Palmer river of York peninsula, from Mount Daintree, for 60 miles. This locality is in lat. 16 deg. S. The Cloncurry river mines are 200 miles south of the Gulf of Carpentaria.

The gold raised in 1872 throughout the colony amounted to £660,396. The yield is now at the rate of 210,000 ounces a year. Copper mining is expected to be a great industry. The Peak Downs mine has yielded a million pounds' worth of metal. The dividends in five years were £215,250. Mount Perry, of the Burnett district, is a more southern center of copper-working. Kroomhit is also rich in ores. Nebo, West Moreton, and Trevelton creeks are hopeful places. Virgin copper and malachite are got from Cloncurry Australian mine, as well as from Rannes on the Upper Downson. Cressbrook, 40 miles from Ipswich, Rawbelle, Edina, Boolboonda, and Normanby, are well spoken of for copper. The new tin exports for 1872 amounted to the large sum of £109,816. Stanthorpe, rightly named, is the center of the southern stanniferous field by the Severn river. The area is called 550 square miles, and the country is granitic. The metal is also found at the head of the Burdekin and other more northern rivers. Stanthorpe, Quart Pot creek, 36 miles from Warwick of the Darling Downs, was the first favorite locality for stream-tin. Sugar-loaf creek, Four Mile creek, Kettle swamp, Pike's creek, and Folkstone are other prominent workings. Iron ore is common enough from the southern boundary up to lat. 20 deg. The Loggan, the Burrum, the Burnett, the Sixty of Broad Sound, and all coal localities are rich in iron. Brown hematite abounds at Toowoomba and Bandamba creek, red hematite at Pine Mountain of West Moreton, specular at the Gilbert, and micaceous iron ore at the Cloncurry. Mercury, in the state of cinnaur, occurs at the head of the Mary, on the Clarke, and at Kilkivan diggings. It is not yet worked. Antimony is got at St. John's creek and the Burnett. Manganese, with nickel and cobalt, are known near Gladstone; and bismuth is brought down from the Cloncurry. The Galena of Ravenswood and the Gilbert may turn out some day valuable silver mines. Coal is of such consequence at the present day that the prospects of Queensland as to that mineral need stating.

SALT MANUFACTURE.—A *Call* correspondent says: The manufacture of salt is one of the local interests of Alameda county. There are salt works at Alameda, San Lorenzo, Mount Eden, Alvarado and Centerville. The works of J. A. Plumber, at Mayhew's Landing, below Centerville, are the most southerly in the county. They are called by the proprietor the Crystal Salt Works. The works occupy some forty acres of land for evaporating ponds, buildings, etc. In winter the water is let in by means of a flood gate, and is pumped by wind-mills and conducted by flumes from one pond to another, as it goes through different degrees of evaporation. About the 1st of June the salt will be crystallized. It will then be raked up and ground. About this time, some forty men will be employed at the works. The proceeds of these works are stated at 2,500 tons per annum. The salt interest of this county has been in a depressed condition for some time, on account of the opposition of the Pacific Salt Company, which has run down prices in the hope of breaking up the manufacture here. The Pacific Company has failed in this; but still the opposition is kept up, and consequently depressed prices are the rule. The average price received for the salt made here is \$10 per ton; the lowest is \$7, and the highest \$20. Mr. Plumber claims that he makes salt equal to the best imported from Liverpool. These works are seven miles from Niles station. Mr. Plumber employs a schooner to carry his salt to market. Since this item was written a correspondent states that there are at least 25 of these factories. In the vicinity of Mount Eden alone there are fifteen or eighteen.

TELEGRAPHIC PROGRESS.—In the course of last year the Telegraph Construction and Maintenance Company, Limited, carried out the following works: The laying of a cable for the Anglo-American Company between Valencia and Heart's Content, Newfoundland, and two cables between Placentia and Sydney, Cape Breton, a length of 2,470 nautical miles. Both sections of the French Atlantic cable of 1869 were also successfully repaired last year.

The Haywood Coal Interests.

Within a few days, operations will be resumed at the H. A. coal mine on Sulphur Spring creek, and with a most cheerful prospect of success. The machinery is all in place and arranged, and only a few hours will be required to clear the shaft of water and enable the miners to proceed with expedition and safety. The pumping apparatus is of very simple construction, and is admirably adapted to the purpose. It was all manufactured here, and is extremely creditable to the invention and skill of the constructors, of whom we shall have more to say after a while. The excellence of such machinery consists in its simplicity, strength, safety and power, and all these are combined in the apparatus in question. Under the superintendence of Mr. Ward, the greatest care has been taken to provide against the possibility of accident, and in that respect we have never seen any mining works so well arranged. The object of these works is not to find coal, for that has been already discovered, but to ascertain the quantity available in that location. All persons having any acquaintance with the coal regions of the East agree that the prospects here are most encouraging; every natural indication has been revealed in the course of the work thus far, and we do not entertain a doubt that a few months' work with the excellent machinery now available, will bring the enterprise to complete success. Nor have we a doubt that the entire westward slope from Mount Diablo to Santa Cruz is one vast coal-field; and our reasons for this impression will be given at some future time. There are two other discoveries in this neighborhood, which we intend to visit and examine before long, and then we shall be prepared to make a more elaborate and satisfactory statement concerning an industrial interest which is of vast importance to the whole surrounding country. Thus far the developments of the H. A. mine have been of the most encouraging and conclusive nature, and we think our citizens may reasonably and confidently expect the creation of a new source of life and prosperity.

Since the above was put in type, we have been informed that work was commenced on the shaft this morning.—Haywood (Alameda Co.) *Advocate*.

THE ST. GOTHARD TUNNEL.—The length of this immense tunnel will be 14,900 metres, or nine miles, 715 yards. The altitude of the northern entrance at Goeschenen will be 1,110 metres above the level of the sea, and that of the southern entrance 1,155 metres. The highest point in the interior of the tunnel will be 1,162½ metres above the level of the sea, which will be reached by a rise from the Goeschenen end of seven per 1,000; from this point there will be a descent towards Airolo of 1 per 1,000. The rock to be traversed is, for the most part, mica-gneiss and mica-schist. Great improvements are stated to have been introduced in the perforating machinery employed, but thus far the progress of the works can scarcely be said to have been very rapid. The length of tunnel actually pierced is, however, a little more than 700 metres on each side, and an advance of three metres (or ten feet) is daily made on each gallery at Goeschenen, the rock being perfectly solid, requiring neither planking nor arching; but at Airolo it is necessary to line the gallery and arch the roof with masonry.

THE CUYAMACA CASE.—The San Diego Union of April 11th has the following: A letter from Washington, dated March 28th, informs us that the Cuyamaca grant case will be finally disposed of within the coming six or eight weeks. The case is now pending before the Secretary of the Interior on an appeal taken by the grant claimants from the decision of Commissioner Drummond. There is not the least probability that the decision of the Secretary will differ from that of the Commissioner. But it is important to the welfare of our mining interests that a final settlement of the case by the highest authority shall be made as speedily as possible. There is no doubt at all that the mine of the Julian section possess great and permanent value, and upon the definite adjustment of the title to the land, the capital so necessary to the development of these mines will be forthcoming. At present the outlook for the mining interest of this county is brighter than at any period since the discovery of the mineral deposits.

SOUTH AUSTRALIAN MINES.—The principal copper mines at the present time are at Bremer, 25 miles from Adelaide; Kasmantoo, 25; Reedy Creek, 32; Capunda, 50; Moonta, Yelta, Wheel James, Wallaroo, 85; Burra Burra or Kooranga, 100; Burrowing, 150; Prince Alfred, 160; Blinman, 262; Burr, 300; and Yudanmutna, 325. Those at work for Bismuth are Daly and Stanley, 328 miles. Cobalt is found at Catarpe, 100. The silver working mines are Glen Osmond, 4 miles; Ben Lomond, 10; Almanda, 12; Wheel Cogill, 48; and Talisker, by Cape Jervis, 54 miles from Adelaide. The metalliferous region extends all along the main range northward from Cape Jervis to Blanchewater, 500 miles. The copper for the year, to June, 1873, brought, £796,513.

GRAVEL, yielding six cents to the pan, has been struck in a cañon eight miles from Salt Lake, by two California miners. At eight feet deep they obtained 11 cents to the pan.

DURING March the total shipment of ores from the Comstock to the various mills, by rail, was 3,675 car loads, or 55,135,000 pounds.

The object of this school is to impart a thorough edu-
cation in business affairs. It is open to persons of both
sexes and of all ages. There is an English Department
for those not sufficiently advanced for the Business
Course. Sessions continue day and evening throughout
the year. Students can enter at any time. All wishing
to be successful should secure a practical education at
this College. Send for "Heald's College Journal," and
learn full particulars. Sent free to all by addressing
E. P. HEALD, Pres. Business College, San Francisco,
Cal. 2v27-ly

ARE YOU GOING

TO PAINT?

THEN USE THE BEST.

THE AVERILL CHEMICAL PAINT
WILL LAST THREE TIMES AS LONG as the best lead
and oil, without CHALKING; is of any desired color.
It is prepared for immediate application, requiring no
Oil, Thinner or Drier, and does not spoil by standing
any length of time. It is equally as good for inside as
outside work; over old work as well as new; in fact,
where any paint can be used the AVERILL CHEMICAL
PAINT will be found superior to any other. Any one
can apply it who can use a brush, which truly makes it
the FARMER'S FRIEND.

IT IS JUST THE PAINT FOR THE AGE.

IT IS SOLD BY THE GALLON ONLY.

One gallon covers 20 square yards 2 coats.

For further information send for sample card and
price list.

GRAND INDUSTRIAL EXHIBITION,

To be held under the auspices of the

MECHANICS' INSTITUTE

OF SAN FRANCISCO, CALIFORNIA,

Opening on August 18th, 1874.

The Board of Managers herewith announce that a
grand Industrial Fair will be held in the city of San
Francisco for 30 days, opening on August 18, 1874.

In view of the increasing commercial and manu-
facturing importance of San Francisco, its contiguity
to close connection with the various countries
bordering on the Pacific, the managers have constructed
a Pavilion, having a floor area of 150,000 feet, and have
invited to it all who are disposed to come and exhibit.
All exhibitors will be placed on the same footing.
 motive power will be furnished free.

The building will be open day and evening, and every
facility will be extended to exhibitors and visitors.

Application for space must be made without delay to
the Secretary of the Board of Managers, 27 Post
street, San Francisco, and all inquiries will be
answered and information extended promptly.

No space can be secured unless applied for before
the 20th of July next. A. S. HALLIDIE, Pres.

13v28-3m J. H. OULVER, Sec'y.

The Sovereigns of Industry.

This new Order seems to be coming prominently before people, especially in the Western States. The National organization is now completed, as well as that of the Order at large. The ritual and all the work has been prepared with the greatest care, and is pronounced of a high character. The Sovereigns of Industry, as is generally known, have been organized to accomplish for mechanics and producers in general, other than tillers of the soil, what the Patrons of Husbandry are doing for the farmers. The "Patrons of Industry," which began to attract some attention last fall, seem to have been gotten up in haste, to anticipate this new organization, and are now generally pronounced a failure—and by some a swindle.

The new movement seems to be very generally approved by the Patrons, although it is recommended that they should not, as a general thing, take hold of it—their own organization being all sufficient, and all that is needful for them to support. Still, important encouragement has been given to it by the members of the late National Grange, inasmuch as some 20 of the Masters of State Granges received the "work" at St. Louis, with the special purpose of introducing it into their respective States. Among that number was Bro. J. W. A. Wright, of this State, who will probably introduce it here immediately after his return, from the visit he is now making to his friends at the East.

The objects of the Order are briefly set forth in the following preamble to the constitution of the National Council:

"The industrial classes are the main producers of the material wealth of the world—that they are the real sustainers of the Government in peace and war, and that they are 'deprived of the full measure of benefit from the wealth they produce and of that large measure of influence in the conduct of public affairs to which justice fairly entitles them; and recognizing that it is only by combined effort that great public wrongs are righted and great public benefits secured,' the Order of the Sovereigns of Industry is instituted 'for the suppression of these evils, the promotion of justice, and for the purpose of improving the material condition of the working classes and raising them to a higher level of social and intellectual life.'"

The question of membership is fixed by the following article in the Constitution:

"Any person engaged in industrial pursuits, not under 16 years of age, of good character, and having no interests in conflict with the purposes of this Order, shall be eligible to membership, and no distinctions in regard to rights and privileges of membership shall be made by this Council, or by a State or subordinate Council, on account of sex, creed, race or nationality."

Hemp, Flax and Jute.

Says a high authority in agricultural and economical matters: Our textile products are becoming sadly neglected. Ten years ago hemp was quite an important product, and now we find it in a state of sad neglect. The world demands it as much as ever, and yet it is falling into neglect. Flax is another fiber that can be grown with success and in demand as such, as well as for its seed as an oil-producing and feeding product. Jute takes an important position.

The demand for grain sacks and hurlaps has increased to such an enormous extent within the last few years, that as an article of commercial importance, the manufacture of jute has become one of the great commercial staples of both this country and Europe—ranking second only to the grain itself, and heading the list in all our commercial records. This fact is so thoroughly established, so patent to every body, and so well understood by those familiar with the subject, and has been discussed and advocated so frequently and at such great length by the leading newspapers of the country within the last few months, that it would almost seem superfluous to urge the consideration of such an enterprise for encouragement at the hands of the public; yet the public, and particularly the farmers, are invited to lend their co-operation to the enterprise, as one promising the fullest success, not only in supplying an indispensable requisite, but promising to be highly remunerative to stockholders as an investment.

The mere question of begging is running into the millions of dollars. Several of our indigenous plants are of great value for their fiber, as the Northern ramie or *artemisia purpurea*, and are worthy an extended trial.

A COLFAX CONCERT.—The pupils of the public school, Mr. Fenton, principal, recently held two evening concerts, creditable alike to teachers and scholars. Julia M. Traphagan, a miss of 11 years, for her "Deisy" song received the heartiest applause of the large and respectable audience. Willie Loebner and Ida Hayford, as miniature peasants, rendered the "Irish Lover's Departure" with equal credit.

NUGGET.—A thirty-ounce gold nugget was recently found in the Bald Mountain mine, Sierra county. It is said that this company are taking out over 300 ounces per day.

THE MANHATTAN MILL AND MINING COMPANY.—At Austin, shipped bullion valued at \$140,000 to New York during the month of March.

Hudspeth's Improved Bail for the Inclined Spout of Headers.

This invention, which is herewith illustrated, is an improvement in the construction and mode of attaching the bails of the inclined spouts of headers, which support the spout and to which a rope or chain is attached, passing thence to some part of the machine where it is made fast. These bails are ordinarily made curving, like a pot bail, and the rope is secured near their center. As the rope is carried back at an inclination to the spout, the latter is not at all times equally supported. The inventor, Mr. W. G. Hudspeth, of Santa Rosa, claims that a bail made according to his plan is far preferable to the ordinary hoop bail, as the former acts as a regulator to the chute, which the other does not.

Mr. Hudspeth's invention contemplates the use of a bail which is made with two parallel sides, having supporting hooks at their lower ends. The upper ends are united by a cross-bar, which is formed in the same piece as the sides, and so as to leave an eye at each corner, to which to attach a chain passing from one side to the other. A link encircles this chain, and to this link the sup-

Improved Bail for Header Spouts.

porting chain or rope is fastened, the link being free to move from side to side between the eyes.

In the illustration are shown the two parallel side pieces, A, A, of the bail. These sides and the cross-bar, B, are bent from a single piece so as to leave the eyes, C, C, at each of the top angles. The lower ends of the side pieces, A, A, are provided with hooks, D, D, which are joined to the sides of the spout by eye-bolts or otherwise. The cross-bar, B, is clasped by the link, E, loosely, so that the latter may move along it freely. The rope or chain, which passes over the usual pulley and thence to the point of attachment on the header, is shown at G, secured to the link, F.

The operation of the device will be as follows: The bail will support each side of the spout equally, and thus regulate the strain upon it as the weight shifts. As the header moves over the ground, and the spout takes various positions and angles, it is evident the elongated link, F, will slip from side to side upon the chain, G, and thus transfer the support of the chain, G, more or less directly over the place where it is most needed.

Improvements in agricultural machinery are fast becoming limited to particular working parts of the leading types of machines. As the patents upon different working portions of the more complicated printing press or loom multiply, so do the patents upon special parts of the threshers, reapers, headers, plows and other farm implements increase. In the invention which we have described, there is what would appear to be a very important improvement in a part so simple that, whatever its defects, few have thought of enlarging upon it.

ALL the mills along the Carson river are running to their full capacity. As yet the wagon roads are not in first-rate order, but the teamsters manage to haul sufficient ore to the outside mills to keep them in operation.

THE Floral mill at White Pine has just been overhauled and put in order. The stamps will now drop 90 times per minute instead of 72 as heretofore.

FIRE.—The town of Colfax was afflicted with a fire this week, which destroyed about half of the business part of the town. About forty-five buildings in all were burned.

SUPPLIES at the Caesar mines are quite limited; prices are as follows: Flour, 75c.; bacon, \$1; sugar, \$1; tea, \$2.50; tobacco, \$3 per pound.

WORK on the Palisade and Eureka Narrows has been resumed.

Academy of Sciences.

A regular meeting of the California Academy of Sciences was held on Monday evening, Vice-President Hewston in the chair. The donations to the museum of the Academy were large and interesting. Among them were the following:

From F. Gruher, collection of birds, embracing eight specimens.

From J. C. Merrill & Co., collection of fishing implements, lines, bows, bundle of arrows, and a rook with a polished groove, supposed to have been used for sharpening spears and other implements, from the South Pacific Islands.

From W. W. Russell, a cluster of hercules taken from the bottom of the iron ship *Milicet*, after a voyage of six months and three days, from Bombay to Liverpool. Thirteen tons of this material were taken from the bottom of the ship. Also, from the same gentleman, a rock-bearing mollusc, from the Choumagin Islands, and egg of the small black terrapin.

From E. F. Loring, rare specimen of crane, from Santa Barbara.

From W. N. Lockington, specimen of crab, crawfish, two species of *orchestia*, or sand-hoppers, two species of lizards, a fresh water salamander, and a curious insect, found running in the sand, thrown up by the tide near Fort Point.

From Dr. G. C. Woods, Surgeon U. S. Navy, a large and valuable collection of specimens from islands of the Pacific, embracing a suit of armor, made from cocoa-nut fiber, from the island of Apia, of the Gilbert group; rope made of cocoa-nut, covered with banana fiber, from Atoli; sennit of cocoa-nut fiber, matting of banana leaf, helms of the same, woven in native looms, and worn by the chiefs, from Ascension Islands; a great variety of similar manufactures, representing the arts of different islands; head decorations, from the Navigator Islands; fishing implements, weapons, etc. This extensive donation was collected by Dr. Woods during four years' cruising in the Pacific, in Government vessels.

Dr. J. S. Hudson, of Oakland, read a paper descriptive of an ancient shell mound in that town.

Dr. Pourgeard read a paper, entitled "General scientific hypothesis as an introduction to a work on evolution of the inorganic and organic world."

Dr. H. Gibbons, Sen., communicated some experimental information on the growth of the potato, and exhibited specimens from his garden that had the peculiar tendency of developing in the ground without throwing out stems.

Mr. Gibbs announced that Major Sparrow Purdy, a corresponding member of the Academy, now at the head of a large expedition in Upper Egypt, had been making large collections of curiosities, for the Academy's museum. Major Purdy will be able to ship his collection in June, and it will probably arrive here some time in August.

After this announcement was made, Dr. Blake read a paper denouncing the management of the Academy and every body else, except himself. The Doctor has a little plan for dividing up the academy into fellows, resident members, etc., which no one else but himself wants to adopt, and he periodically bursts out on his favorite subject. "This time," he read a paper reflecting severely on certain ones of the Trustees, and stirred up a pretty lively discussion in which he was handled without gloves by several of the members. The opinion of most of the members was that Dr. Blake was out of humor because he had not been elected to an office, as he took occasion to air some of his grievances while reading his paper. He wants at least four scientific men in the Board of Trustees, and his amendment to the constitution provides for this. The amendment is not at all necessary, for there are at least four there now. Professor Davidson, R. E. C. Stearns, Col. Gray and Henry Edwards. It is hardly probable that the Doctor's plan will amount to anything, but it is to be hoped that the committee appointed to investigate Dr. Blake's charges will effectually suppress him. He is breeding dissension and doing more harm than good to the Academy.

A SEAT in the San Francisco Stock and Exchange Board was sold this week to a New York operator for \$10,500.

QUICKSILVER miners in Sonoma county have had to employ Chinamen, as they could not get white men at \$3 per day.

MONTEREY COAL.—Some 500 tons of coal are said to have been taken from the newly discovered mines near Monterey.

THE Granite Tunnel mine and mill, near Placerville, has been sold to Lucas, Pertridge & Co., for \$20,000.

Last week a carload of miners arrived in Gold Hill, from Camhorne, Cornwall.

CINNABAR mines are being developed on Silver creek, Santa Clara county.

New Inventions!

Of real merit, it brought plainly before the public when fresh, are most likely to become profitable to the patentee. For this reason, patentees (of worthy devices) should have the best of Engraving Made, and published in the Press. Superior Engraving Made, at reasonable rates, by artists in this office.

PATENTS & INVENTIONS.

A Weekly List of U. S. Patents Issued to Pacific Coast Inventors.

[FROM OFFICIAL REPORTS FOR THE MINING AND SCIENTIFIC PRESS, DEWEY & CO., PUBLISHERS, AND EDITORS OF U. S. AND FOREIGN PATENT AGENTS.]

By Special Dispatch, Dated Washington, April 21, 1874.

FOR WEEK ENDING April 7, 1874.

MILK-PAIL.—Ledyard Frink, Rio Vista, Cal.

CAR-COUPLING.—Jacob F. Buruer, Elko, Nevada.

MEDICAL COMPOUND.—Hawkins W. Epperly, Cambria, Cal.

CLASP FOR STOCKING SUPPORT.—Edward Halsey, San José, Cal.

DESIGN.

CENTRE-PIECE.—Samuel Kellett, S. F., Cal.

"The patents are not ready for delivery by the Patent Office until some 14 days after the date of issue. Copies of U. S. and Foreign Patents furnished by Dewey & Co., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business, for Pacific coast inventors transacted with perfect security and in the shortest time possible."

The Mining & Scientific Press

Started in 1860, is one of the oldest weekly journals now published in San Francisco. It has been conducted by its present proprietors for ten years, during which period it has been repeatedly enlarged and constantly improved. The active and steadfast efforts of its publishers have gained for its conduct an amount of practical experience greater than any other publishers have accumulated on this coast, of a weekly journal.

The sum paid by us for the best editorial talent obtainable for our special class journal; for engravings, for interesting news and correspondence, and for printing a large-sized, handsome sheet, is unequalled by that of any other American weekly west of the Mississippi.

As a PRACTICAL MINING JOURNAL it has no rival on this coast.

It is the only MECHANICAL, and the only SCIENTIFIC journal of the Pacific States.

Every Miner, Assayer, Millman, and Metallurgist in the United States should take it.

Every Pacific Coast Mechanic, Engineer, Inventor, Manufacturer, Professional Man, and Progressive and Industrial Student should patronize its columns.

Every Mining Engineer, Superintendent, Metallurgist, Mine Owner and Mine Worker in the world should profit by its illustrations and descriptions of New Machinery, Processes, Discoveries and Record of Mining Events.

Every intelligent thinker in the land, in high or humble station, who would avoid literary trash for genuine information, should SUBSCRIBE AT ONCE.

TWO MONTHS DEWEY & CO., 311 N. 3rd St., San Francisco.

THE NEW U. S. MINING LAWS.

The new Laws of 1872, governing the location and purchase of Placer and Quartz Mines and Agricultural Lands in Mining Districts of the U. S., printed in circular sheet, for sale at this office. Single copies, 25 cts.

Rabbit Culture.

Necessity is the mother of invention, and a hundred devices are now in vogue in England to meet the difficulties consequent on the high price of butcher's meat. Prominent among these is rabbit culture. A number of places have lately been started for this purpose in London, and they are said to be paying very well. At these places rabbits are being bred in large numbers, and if they increase at their present rate they will make an appreciable addition to the food of London.

Lately the first annual show of the Metropolitan Rabbit Association was held in the same city, when there was a numerous collection of rabbits exhibited. They were generally what is known as the long-eared breed, and the size and weight of nearly all the specimens exhibited were extraordinary. There was no rabbit in the show less than eight pounds in weight, and two of them weighed respectively eleven pounds four ounces and eleven pounds. The first prize was awarded for a rabbit five months old, and weighing ten pounds. This animal's ears were 26 1/2 inches long, and 6 1/2 inches wide, and it should here be stated that a few days before the show it was purchased for breeding purposes for the large sum of £20. The second prize was awarded to a rabbit eight months old, and weighing ten pounds ten ounces. Its ears were 23 1/2 inches in length, and 5 1/2 inches in width. During the exhibition the chairman of the association addressed the company assembled, and, referring to the present high price of meat, stated that the association had been mainly established to encourage the breed of rabbits, which could be largely and profitably produced and reared. He urged the desirability of a wider and more extended production of rabbits as an article of animal food at a time like the present, when beef and mutton were beyond the reach of large portions of the population.—*Poultry Bulletin.*

THE FARE AND FREIGHT QUESTION.—Some few injudicious people of "Placer" county recently burned Assemblyman Gilman of that county, in effigy, at Shingle Springs, whereupon an endeavor was made to show that the feeling of the people in that place was in sympathy with Mr. Gilman, notwithstanding the act of burning. As an offset to this, effort a mass meeting of the citizens was subsequently called, which, although it did not endorse the unwise demonstration of the effigy burners, yet passed some most scathing resolutions condemnatory of the course of Mr. Gilman on the Fare and Freight question. There is no mistaking the opinion of the people of California on this question, and they will not fail to embrace the first and every proper opportunity to make it known. All those who, like Mr. Gilman, misrepresented their constituents at Sacramento, last winter, will receive a most signal rebuke from the people at the next general election.

The blower for the Sacramento smelting works arrived from Boston on Tuesday. It weighs twenty-one hundred pounds.

PAIN-KILLER.

1840. 1874.
Time Tests the Merits of All Things.

THIRTY YEARS is certainly long enough time to prove the efficacy of any medicine, and that the Pain-Killer is deserving of all its proprietors claim for it, is amply proved by the unparalleled popularity it has attained. It is a sure and effective remedy. It is sold in almost every country in the world, and it needs only to be known to be prized, and its reputation as a Medicine of Great Virtue, is fully and permanently established. It is the great Family Medicine of the age. Taken internally, it cures Dysentery, Cholera, Diarrhoea, Cramp and Pain in the Stomach, Bowel Complaint, Painters' Colic, Liver Complaint, Dyspepsia, or Indigestion, Sudden Colds, Sore Throat and Coughs. Taken externally, it cures Bruises, Blisters, Felons, Cuts, Burns, Scalds, Old Sores and Sprains, Swellings of the Joints, Toothache, Pain in the Face, Neuralgia and Rheumatism, Chapped Hands, Frost Bitten Feet, etc.

Pain is supposed to be the lot of our poor mortals, as inevitable as death, and liable at any time to come upon us. Therefore, it is important that remedial agents should be at hand to be used on emergency, when we are made to feel the excruciating agony of pain, or the depressing influences of disease. Such a remedial exists in Perry Davis' "Pain-Killer," the fame of which has extended over all the earth. Amid the eternal ices of the Polar regions, or beneath the intolerable and burning sun of the tropics, its virtues are known and appreciated. And by it suffering humanity has found relief from many of its ills. The effect of the Pain-Killer upon the patient, when taken internally in cases of Cough, Cold, Bowel Complaint, Cholera, Dysentery, and other affections of the system, has been truly wonderful, and has won for it a name among medical preparations that can never be forgotten. Its success in removing pain, as an external remedy, in cases of Bruises, Sprains, Sore and Swellings, Cuts, Stings of Insects, etc., and other causes of suffering, has secured for it the most prominent position among the medicines of the day. Beware of counterfeit and worthless imitations. Call for Perry Davis' Vegetable Pain-Killer, and take no other.

Sold by Druggists and Grocers.

Sixteen well filled pages.
Original and Choice Engravings.

DEWEY & Co.,

Publishers, No. 338 Montgomery Street, S. F.

Scientific and Practical Books on Mining, Metallurgy, Etc.

Published or issued, wholesale and Retail, by DEWEY

CO., MINING AND SCIENTIFIC PRESS OFFICE, S. F.

BY GUIDO KUSTEL,

MINING ENGINEER AND METALLURGIST.

Roasting of Gold and Silver Ores, and the Extraction of their Respective Metals without Quick-silver. 1870.

This rare book on the treatment of gold- and silver-ores without quicksilver, is liberally illustrated and crammed full of facts. It gives short and concise descriptions of various processes and apparatus employed in this country and in Europe, and explains the why and wherefore.

It contains 142 pages, embracing illustrations of furnaces, implements and working apparatus. It is a work of great merit, by an author whose reputation is unsurpassed in his speciality.
Price \$2.50 coin, or \$3 currency, postage free.

Concentration of Ores (of all kinds), including the Chlorination Process for Gold-bearing Sulphurets, Arseniurets, and Gold and Silver Ores generally, with 120 Lithographic Diagrams. 1867.
This work is unequalled by any other published, embracing the subjects treated. Its authority is highly esteemed and regarded by its readers; containing, as it does, much essential information to the Miner, Metallurgist, and other professional workers in ores and minerals, which cannot be found elsewhere in print. It also abounds throughout with facts and instructions rendered valuable by being clearly rendered together and in simple order. It contains 120 diagrams, illustrating machinery, etc., which alone are of the greatest value. PRICE REDUCED TO \$5.

Nevada and California Processes of Silver and Gold Extraction, for general use, and especially for the Mining Public of California and Nevada, with full explanations and directions for all metallurgical operations connected with silver and gold from a preliminary examination of the ores to the final casting of the ingot. Also, a description of the general metallurgy of silver ores. 1864.

As its title indicates, this work gives a wide range of information, applicable to all vein miners and workers in precious metals, affording hints and assistance of exceeding value to both the moderately informed and the most expert operator.
Price, \$5 in cloth; \$6 in leather—coin.

BY OTHER AUTHORS.

The Quartz Operator's Hand-Book; by P. M. Randall. 1871. Revised and Enlarged Edition. Cloth bound, 175 pages. Price, \$2.

Sulphurets: What They Are, How Concentrated, How Assayed, and How Worked; with a Chapter on the Blow-Pipe Assay of Minerals. By Wm. M. Barstow, M.D. 1867; cloth bound, 114 pages. Printed and sold by Dewey & Co. Price, \$1; postage free. The heat written work, and most complete work on the subject treated.

ANY OTHER BOOKS DESIRED will be furnished at the most reasonable rates by Dewey & Co., Mining and Scientific Press Office, S. F.

A Good Binder for \$1.50.

Subscribers for this journal can obtain our Patent Elastic Newspaper File Holder and Binder for \$1.50—containing gilt title of the paper on the cover. It preserves the papers completely and in such shape that they may be quickly fastened and retained in book form at the end of the volume, and the binder (which is very durable) used continuously for subsequent volumes. Post paid, 25 cts. extra. It can be used for Harper's Weekly and other papers of similar size. If not entirely pleased, purchasers may return them within 30 days. Just the thing for libraries and reading rooms, and all who wish to file the Press.

HINTS FOR INVENTORS. We will send on receipt of stamp for postage, FREE, our 32-page Circulars containing 112 Illustrated Mechanical Movements; a digest of PATENT LAWS; information how to obtain patents, and about the rights and privileges of inventors and patentees; list of Government fees, practical hints, etc., etc. Address DEWEY & Co., Publishers and Patent Agents, San Francisco.

DEWEY & Co., American & Foreign Patent Agents,

OFFICE, 38 MONTGOMERY STREET, S. F.

The best, speediest, and surest method for you to obtain patents, file caveats, or transact any other important business with the Patent Office at Washington, or with foreign countries, is through the agency of DEWEY & CO., PUBLISHERS OF THE MINING AND SCIENTIFIC PRESS, SAN FRANCISCO, an able, responsible, and long-established firm, and the principal agents on this side of the continent. They refer to the thousands of inventors who have patronized them, and to all prominent business men of the Pacific Coast, who are more or less familiar with their reputation as straightforward journalists and patent solicitors and counselors. We not only more readily apprehend the points and secure much more fully and quickly the patents for our home inventors, but with the influence of our carefully read and extensively circulated journals, we are enabled to illustrate the intrinsic merits of their patents, and secure a due reward to the inventor, besides serving the public who are more ready to give a fair trial, and adopt a good thing, upon the recommendation of honest and intelligent publishers.

To Obtain a Patent,

A well-constructed model is generally first needed, if the invention can well be thus illustrated. It must not exceed 12 inches in length or height. When practicable, a smaller model is even more desirable. Paint or engrave the name of the article, and the name of the inventor, and his address upon it.

Send the model (by express or other reliable conveyance), plainly addressed, to "DEWEY & Co., MINING AND SCIENTIFIC PRESS OFFICE, SAN FRANCISCO." At the same time, send a full description, embodying all the ideas and claims of the inventor respecting the improvement describing the various parts and their operations.

Also send \$15. currency, amount of first fee of the Government. The case will be placed on our regular file, the drawings executed, and the documents made up, and soon sent to the inventor for signing.

As soon as signed and returned to us with the fees then due us, it will be sent straightway to the Patent Office at Washington.

When the invention consists of a new article of manufacture, a medicine, or a new composition, samples of the separated ingredients, sufficient to make the experiment (unless they are of a common and well-known character), and also of the manufactured article itself, must be furnished, with full description of the entire preparation.

For Processes, frequently no model or drawings are necessary. In such case, the applicant has only to send us an exact description, and what is desirable to claim.

For designs no models are necessary. Duplicate drawings are required, and the specifications and other papers should be made up with care and accuracy. In some instances for design patents two photographs, with the negative, answer well instead of drawings.

For further information, send a stamp for our illustrated circular, containing a digest of PATENT LAWS, 112 illustrated mechanical movements, and HINTS AND INSTRUCTIONS regarding the RIGHTS AND PRIVILEGES of inventors and patentees, which will be furnished post paid. Also a copy of NEW PATENT LAW of 1870.

Address DEWEY & Co.,

PUBLISHERS, PATENT AGENTS AND ENGRAVERS,

No. 338 Montgomery Street, S. F.

SHAREHOLDERS, TRUSTEES, and SECRETARIES of ALL MINING COMPANIES,

Should see to it that their Notices are advertised legally in the MINING AND SCIENTIFIC PRESS, at much less cost than the usual rates of daily publications. Every person interested in the prosperity of legitimate mining enterprises should favor such practical economy. Send for circular of convenient dates for advertising, free blanks, and a copy of the New Code Corporation Assessment Law.

Mining and Other Companies.

On the 1st of the present month the present large edition of the M. & S. Press, are obliged to go to press on Thursday evening—which is the very latest hour we can receive advertisements.

Land Purchasers' Association—Office, No.

425 Kearny Street, San Francisco, Cal. Notice is hereby given that at a meeting of the Directors or Trustees of this corporation, held on the 14th day of April, 1874, an assessment of ten dollars per share (being the 4th monthly installment on the subscription to the stock) was levied upon the capital stock of said corporation, payable immediately, in United States gold coin, to the Secretary, at No. 425 Kearny Street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 15th day of May, 1874, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Monday, the 26th day of May, 1874, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

Office, No. 425 Kearny Street, Room No. 2, San Francisco, California.

N. B. This assessment is levied to pay the balance due for grading Washington Street.

Diamond Silver Mining Company.—Loca-

tion of works, East Tintic Mining District, Utah

County, Utah Territory. Principal place of business, San Francisco.

Notice is hereby given that at a meeting of the Board of Directors, held on the 18th day of April, 1874, an assessment of ten (10) cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Treasurer, J. H. Fish, at the office of the Company, No. 123 Post Street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 1st day of June, 1874, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Thursday, the 26th day of June, 1874, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

Office—No. 123 Post Street, San Francisco, Cal. ap23

Jefferson Gold and Silver Mining Com-

pany. Location of principal place of business, San Francisco, Cal. Location of works, Brown's Valley, Yuba County, California.

Notice is hereby given that at a meeting of the Board of Directors, held on the 26th day of March, 1874, an assessment of fifty cents per share was levied upon the capital stock of the corporation, payable immediately, in United States gold coin, to the Treasurer at the office of the Company, Nos. 214 and 216 Pine Street, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on the 1st day of May, 1874, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on the 1st day of June, 1874, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

C. V. D. HUSSARD, Secretary.

Office—214 and 216 Pine Street, San Francisco, Cal. ap23

Public Notice is hereby given by order

of Board of Trustees, that the annual meeting of the stockholders of the Lumber and Gravel Mining Company will be held on Saturday, the 18th day of April, at 2 o'clock p. m., for the purpose of electing a Board of Trustees for the ensuing year and to transact such other business as may come before the meeting, at the office of the company, No. 321 Montgomery Street, Room 17, San Francisco, April 20, 1874.

Adjournd until May 2, 1874.

Mount Saint Helena Gold and Silver

Mining Company. Principal place of business, San Francisco, California.

NOTICE.—There are delinquent upon the following described stock, on account of assessment levied on the 10th day of March, A. D. 1874, the several amounts set opposite the names of the respective shareholders as follows:

Names.	No. Certificate.	No. Shares.	Amount.
Swift, J. H.	75	50	\$5 00
Brady, John	79	6	50
Badlam, A. C.	62	50	5 00
Badlam, A. C.	63	100	10 00
Winans, J. W.	60	1800	180 00
Tietreau, O. L.	75	10	1 00
Wills, W. B.	61	50	5 00
Tourtel, E. C.	88	10	1 00

And in accordance with law and an order of the Board of Directors, made on the 10th day of March, A. D. 1874, so many shares of each parcel of said stock as may be necessary, will be sold at public auction, at the office of said Company, 418 Montgomery Street, San Francisco, Cal., on Tuesday, the 12th day of May, 1874, at the hour of 1 o'clock p. m., and the day, pay said delinquent assessment thereon, together with costs of advertising and expenses of sale.

Office—No. 418 Montgomery Street, San Francisco, Cal. ap18

Missouri Quicksilver Mining Company—

Principal place of business, San Francisco, Cal. Location of works, Clinchburg Mining District, Sonoma County, California.

NOTICE TO STOCKHOLDERS.—A meeting of the stockholders of the above named company will be held at the office of the company, No. 204 Front Street, San Francisco, the 25th day of April, 1874, at 12:30 p. m., for the purpose of adopting By-Laws for the company, and such other business as may be brought before the company. By order of the Board of Directors.

Office of the Company, 204 Front Street, San Francisco, Cal. ap4

Mansfield Gold Mining Company—Loca-

tion of principal place of business, San Francisco, California. Location of works, El Dorado, California.

Notice is hereby given that at a meeting of the Board of Directors, held on the 21st day of March, 1874, an assessment of twenty-five cents per share was levied upon the capital stock of the corporation, payable immediately, in United States gold coin, to the Secretary, at the office of the company, No. 331 Kearny Street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 27th day of April, 1874, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Monday, the 18th day of May, 1874, to pay the delinquent assessment together with costs of advertising and expenses of sale.

Office—Room 14, No. 331 Kearny Street, San Francisco, California.

Starlight Gold and Silver Mining Compa-

ny. Location of works, Humboldt County, Nevada.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 19th day of March, 1874, an assessment of twenty-five cents per share was levied upon the capital stock of the corporation, payable immediately, in United States gold and silver coin, to the Secretary, at his office in San Francisco.

Any stock upon which this assessment shall remain unpaid on the 25th day of April, 1874, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on the 18th day of May, 1874, to pay the delinquent assessment, together with costs of advertising and expense of sale. By order of the Directors.

DAVID WILDEH, Secretary.

Office, 24 Merchants' Exchange, San Francisco, Cal.

Virginia Consolidated Mining Company.

Location of principal place of business, San Francisco, California. Location of works, Keapage District, Inyo County, State of California.

Notice is hereby given, that at a meeting of the Directors, held on the 11th day of March, 1874, an assessment of \$1.00 of five cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of the Company, San Francisco.

Any stock upon which this assessment shall remain unpaid on the 27th day of April, 1874, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on the 18th day of May, 1874, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

Office—No. 315 California Street, San Francisco, California. (Room No. 13.)

POSTPONEMENT.—The day for deeming stock

delinquent on the above assessment is hereby postponed until the 16th day of May, 1874; and the sale thereof until Wednesday, the 10th day of June, 1874. By order of the Board of Directors.

ap16-3w

Washington Mining Company—Location

of principal place of business, San Francisco, California. Location of works, Mariposa County, Cal.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 27th day of March, 1874, an assessment (No. 8) of one dollar per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of the Company, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 15th day of May, 1874, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Tuesday, the 26th day of May, 1874, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

OVER \$3,500 PER MONTH SAVED BY THE USE OF HENDY'S IMPROVED CONCENTRATOR.

Can be seen at the Manufactory, 32 Fremont Street, San Francisco.

JOSHUA HENDY, Esq.—Dear Sir:—As a practical miner and millman, I take pleasure in recommending the use of your Concentrators in all mills where gold or silver ores are reduced. No mills should be without them for the following reasons:

1st. They are good sizers (no perfect concentration in pulverized ore can be effected without first sizing).
2d. The best Concentrator I have ever known—the concentrated stuff only containing 6 per cent. of sand.
3d. They are good amalgamators, light (feathery) particles of amalgam and particles of coated gold, by attrition are brightened, and from their specific gravity and the action of the pan, fall to the bottom and adhere.
4th. They require but little power and attention to run them, and with ordinary care will last for years.
I have been familiar with the workings of your Concentrators for four years past; have run them myself in the North Star Mine, Grass Valley; am familiar with their practical workings on the Empire Mine, Grass Valley; St. Patrick, Placer Co.; St. Lawrence, El Dorado Co.; Oaks and Reese, Mariposa Co., and most cheerfully give you this testimonial. For further information you are at liberty to refer to,
Yours respectfully,
JAS. H. CROSSMAN, M. E.

409 California street, or Cosmopolitan Hotel.

SAN FRANCISCO, April 27, 1872.

OFFICE SUPERINTENDENT OF KEYSTONE CON. M. CO., AMADOR, AMADOR COUNTY.
MR. J. HENDY—Dear Sir:—In answer to your inquiries as to your concentrators furnished our company last July, I would say that I am more than pleased with them; and the saving to the company has been over \$3,500 per month more than with the blankets and buddies formerly in use.
O. C. HEWITT, Supt.

References:

Reference is made to the following mills, some of which have had HENDY'S CONCENTRATORS in use for over four years:

EMPIRE MILL. (3 Concentrators).....	Grass Valley, Nevada County.
NORTH STAR M. & M. CO. (3 Concentrators).....	Grass Valley, Nevada County.
VULTURE CO. (3 Concentrators).....	Prescott, Arizona.
NOYER & CO'S MILL. (2 Concentrators).....	Prescott, Arizona.
LUCK WINING CO. (3 Concentrators).....	Owyhee District, Idaho.
EL TASTE CO. (3 Concentrators).....	Sonora, Mexico.

These Long Stroke Pumps have large five openings, and are highly esteemed for draining mines.

CAST STEEL SHOE AND DIE COMPANY,

OFFICE—Room 28, Hayward's Building, 419 California St., S. F.

Patented CAST STEEL SHOES & DIES for Quartz Mills.

Price, 20 cents per Pound.

An improvement greatly needed—being Stronger, more Durable and Economical than Cast Iron; as the Dies, when worn down, can be welded to the Shoes as easily as bar steel; never break, keep their full striking surface. Battery of five shoes crushes one-ton more ore in 24 hours than Cast Iron Shoes, will wear as long as four set of Cast Iron Shoes, and can be worn down to 1/2 inch in thickness. The studs can be welded into Picks, Hammers, etc.

—ALSO—

Cast-Steel Tappets, Cams, Hammers,

Gearing and Castings

OF ALL KINDS, A SPECIALTY.

It takes forty days to fill orders.

TREADWELL & CO.'S

UPRIGHT SAFETY ENGINES,

2 to 10 Horse Power.

MADE BY THE N. Y. SAFETY STEAM POWER CO.

Has tubular boiler, and therefore is secure against the dangers common to shell boilers. Power is taken from near the base, which avoids vibration or top-heaviness. Occupies but two feet square of floor space and is so simple a boy can run it. All its parts are easily accessible—a great advantage. Is complete in itself as a Portable Engine and Boiler, or the engine can be detached from the boiler and run independently, if required. Its main points are SIMPLICITY, SAFETY and ECONOMY. For printing offices, laundries, tanneries, ranches, small repair and machine shops, or for hoisting whenever a small and safe power is required, they are peculiarly adapted.

Refer to the following parties who have them in use
E. DETTRICH & CO., Bag Factory, San Francisco;

THE SELDEN DIRECT-ACTING STEAM PUMP,

A. CARR, Manufacturer & Proprietor.

Patented

Aug. 2d, 1870.

Dec. 20th, 1870.

Combining simplicity and durability to a remarkable degree. Its parts are easy of access, and it is adapted to all purposes for which Steam Pumps are used.

As a Mining Pump it is Unsurpassed.

—ALSO—

STEAM, GAS & WATER PIPE, BRASS WORK STEAM & WATER GAUGES, FITTINGS, ETC.

CARR PATENT STEAM RADIATOR.

Send for Price List and Circulars. Address,

A. CARR,

10v28-1y

43 Courtland Street, New York.

TO HYDRAULIC MINERS.

I warn Hydraulic Miners not to be misled by the advertisement of Mr. F. H. Fisher. Said Fisher has been beaten in every suit to which he has been a party (respecting Patent Right on Hydraulic Machines), whether as plaintiff or defendant.

His patrons have already paid over Five Thousand Dollars for license to use machines purchased of the self styled

"Only Reliable Party in the Business Who Protects His Customers."

Fisher's Machine is worthless unless the discharge pipe is furnished with appliances, the patent for which is owned by Messrs. CRAIG, and which Fisher is enjoined from making.

The Machine itself is also an infringement on another patent owned by the same parties.

All persons infringing on either of these patents WILL BE PROMPTLY PROSECUTED.

I am sole LICENSEE to sell Machines manufactured under Craig's, Rice's, Macey's and Hoskin's patents.

I Guarantee Full Indemnity to all my Customers.

Machines of all sizes always on hand. If you want a Machine that will give satisfaction, and do not want to pay for it twice over, buy an Improved LITTLE GIANT.

For further particulars apply to R. HOSKIN, Dutch Flat, Or R. R. & J. CRAIG, Room 6, 240 Montgomery St., S. F. WILLIAMSON & CORY, Marysville, Agents. Dutch Flat, Aug 10, 1873. 6v27-2m

STEEL SHOES AND DIES FOR QUARTZ MILLS.

Made by our improved process after many years of patient research and experiment. We have succeeded in producing STEEL SHOES AND DIES for QUARTZ MILLS, which are unequalled for

Will wear three times longer than any iron Shoes.

BUILDERS AND CONTRACTORS Of Quartz Mills, Pans, Separators, Concentrators, Jigs, Hydraulic Rock Breakers, Furnaces, Engines, Boilers and Shafting, and general Mining Machinery in all its details and furnishers of Mining Supplies. All orders promptly filled.

MOREY & SPERRY, Liberty St., N. Y. Examination solicited. 9v28-1y

THE ONE-PLUNGER JIG,

Delivered on R. R. Car at Denver, Col., or St. Louis, Mo.

Separates in one and the same operation—1. galena and sulphide of silver; 2. pyrites or blende; 3. tailings, containing no valuable parts; or, 1. gold; 2. pyrites; 3. tailings (quartz, etc.) containing no valuable parts; or, 1. copper; 2. tailings, containing no valuable parts. The One-Plunger Jig can be combined with existing stamp-mills with highly important advantages, as after amalgamation it will recover completely all fine metals and all base ores and all mercury out of tailings. It concentrates all fine metal ores to such cleanliness that low grade ores can be shipped, after concentration, as first-class ores. Its feed and discharge are automatic. Its construction offers better guarantee against loss and repairs than any other apparatus in use. For particulars, apply to the inventor,

F. CAZIN, Mining and Civil Engineer, Denver City, Col. L. Box 2225. 13v28-1y

CROCKER'S PATENT TRIP HAMMER QUARTZ BATTERY.

This machine, complete, weighs 1,500 lbs. Has an iron frame, five steel arms with stamps weighing 17 lbs. each, which strike 20 blows per minute, in a mortar provided with screens on both sides, and crushes FINE 600 lbs. per hour, requiring one-horse power to drive it. Has been thoroughly tested, and is guaranteed to give good satisfaction. PRICE, \$900.

G. D. CROCKER, 17v26-1f 315 California street, San Francisco.

THEODORE KALLENBERG, MACHINIST, and Maker of Models for Inventors. All kinds of Dies, Stamps and Punches made. Also, all kinds of Small Gears Cut.

No. 10 Stevenson Street, near First, SAN FRANCISCO.

We purchase high grade Gold and Silver Ores, Bullion, Etc. Ores worked and tested made with care; also, Ore Assays of Gold, Silver, Copper, Lead, Tin, Iron, Manganese, Cinnabar, Nickel, Etc.

Varney's Patent Amalgamator.

These Machines Stand Unrivaled.

For rapidly pulverizing and amalgamating ore, they have no equal. No effort has been, or will be spared to have them constructed in the most perfect manner and of the great number now in operation, not one has ever required repairs. The constant and increasing demand for them is sufficient evidence of their merits. They are constructed so as to apply steam directly into the pulp, or with steam bottoms, as desired.

This Amalgamator Operates as Follows.

The pan being filled, the motion of the mill forces the pulp to the center, where it is drawn down through the aperture and between the grinding surfaces. Thence it is thrown to the periphery into the quicksilver. The curved plates again draw it to the center, where it passes down, and to the circumference as before. Thus it is constantly passing a regular flow between the grinding surfaces and into the quicksilver, until the ore is reduced to an impalpable powder, and the metal amalgamated.

Setters made on the same principle excel all others. They bring the pulp so constantly and perfectly in contact with quicksilver, that the particles are rapidly and completely absorbed.

Mill-men are invited to examine these pans and settlers for themselves, at the office, 229 Fremont Street, San Francisco

E. N. RIOTTE, JAS. L. BEYEA, S. O. BROWN.

AUBURN MILL COMPANY, Reno, Nevada,

Purchase Silver Ore in quantities of ten tons and upwards, delivered on board the cars at San Francisco or Oakland at the annexed Net Rates, with no charge for SAMPLING OR REDUCTION. On lots of less than 10 tons, freight to Reno will be deducted.

Special Rates for Gold Ores.

On Gold contained in Silver Ores to the amount of \$30 and upwards, 63 per cent. will be paid. When less than \$30, and above \$10, the amount will be added to the Silver value. Settlers promptly returned by express or by mail. Ores sampled by Battery or Sampling Mill as shipper may elect, and returns made promptly by cheque on San Francisco.

And on intermediate values in proportion.

C. A. LUCKHARDT, Agent. 21 First St., San Francisco.

S. O. BROWN, Manager, Reno, Nevada. 3v23-6m

Nevada Metallurgical Works,

21 First street.....San Francisco.

Ores worked by any process. Ores sampled. Assaying in all its branches. Analysis of Ores, Minerals, Waters, etc. Plans furnished for the most suitable process for working Ores. Special attention paid to the Mining and Metallurgy of Quicksilver.

E. N. RIOTTE, C. A. LUCKHARDT, Mining Engineers and Metallurgists.

Morris' Settlers and Amalgamator.

PATENTED MARCH 25, 1873.

An important improvement in milling. Cheap, light, efficient and durable. Gains Quicksilver on working tailings. Is discharged from the surface in the center instead of the side, by means of a Syphon which extends to near the center of the Settler. Heaviest casting weighs only 135 pounds. The sides and bottom of the Settler are made of wood, as also Mullers, placed vertically—the friction of which quickens the quicksilver. One of these machines is in daily operation at No. 616 Merchant street, (basement), San Francisco. Parties desiring information as to rights of use, purchase, etc., can address, **FREDERICK MORRIS,** 616 Merchant St., S. F. Ores Assayed and Amalgamated. 8v28-3m

ORE BAGS FOR SALE IN QUANTITIES TO SUIT.

Apply to **CROSS & CO.,** 316 California street, San Francisco.

Richardson & Co., Copper Ore Wharves, SWANSEA.

RICHARDSON & Co. have been for thirty years established in Swansea as Agents for the preparation, Sampling, Assaying, and sale of Copper, Silver, Gold, Lead, Zinc, and all other Ores and Metals, for which they have extensive Warehouses and Wharves under cover, 1,400 feet of Quay Frontage within the Floating Dock, and the most complete Machinery and Appliances. They are also prepared to make advances against Ores in anticipation of realization, and to guarantee all payments when required. 2v26-1y

PLATINUM Vessals, Apparatus, Sheet, Wires, Etc., Etc.

For all Laboratory and Manufacturing Purposes. **H. M. RAYNOR,** 25 Bond street, New York. Platinum Scrap and Native Platinum purchased.

Quicksilver.

Parties working Quicksilver Ores can obtain the right to use highly successful patented improvements for condensing fumes and working soot, by addressing **F. FIEDLER,** 13v28-3m New Almaden.

All Sorts of Steam Boilers Made to Order and Repaired.

Also, all kinds of Sheet Iron Work done promptly, and at prices to suit the time. 1v27

WATER PIPE, FOR SALE CHEAP.

WE HAVE ON HAND

5,000 FEET OF 4-INCH PIPE, 5,000 FEET OF 5-INCH PIPE,

Made of No. 16 Sheet Iron, which we will sell at a very low price. FRANCIS SMITH & CO., 130 Beale street. 7v24-1f

AMERICAN TURBINE WATER WHEEL.

Recently improved and submitted to thorough scientific tests by James Emerson, showing the following useful effect of the power of the water utilized, being THE HIGHEST RESULTS EVER KNOWN.

Percentage of part gate, $\frac{1}{2}$ 50.08; $\frac{3}{4}$ 69.44; $\frac{7}{8}$ 78.73; $\frac{9}{10}$ 82.53; $\frac{10}{10}$ 82.90. Percentage of whole gate, 83.14.

Mr. Emerson says: "These are the best average results ever given by any Turbine Wheel in my experience."

A splendidly illustrated descriptive catalogue, or any further information desired, furnished on application to TREADWELL & CO., SAN FRANCISCO, CAL.

KABATH & LADD, 109 California Street, SAN FRANCISCO.

HAVE JUST RECEIVED IN PRIME ORDER, PER E. I. CURRY, A FRESH SUPPLY OF

EASTERN IRON KEG POWDER,

Manufactured by the World-Wide Known LAFIN & RAND POWDER COMPANY.

Diamond Drill Co. PATENT SAFETY FUSE, Electrical Blasting Apparatus, Electrical Fuse, Rubber Tubing,

LEADING AND CONNECTING WIRE CAPS, ETC.,

MINE & MILL SUPPLIES.

Send for Further Information.

BRONZE TURKEYS. GOBBLER, 43 lbs. HENS, 20 to 26 lbs. Emden Geese.

(Fifty-eight to sixty lbs at maturity.) EGGS FOR SALE NOW. Bramshs, Leghorns, Houdans, Etc.

Send for Price List and Illustrated Circular. Address, M. EYRE, Napa, Cal.

Eggs for Hatching, packed to travel safely by rail or stage and hatch after arrival. 1728-2m

SMELTER OR ASSAYER.

Advertiser, who has had considerable experience in the treatment of Silver and Silver-lead Ores, both in Europe and America, and is a thorough practical Assayer and Analytical Chemist (Fellow of the Chemical Society of London) is open to an engagement in either of the above capacities. References unexceptionable. Address "Argentum," office of this paper. 418-1-1

PACIFIC BRIDGE COMPANY.

WORKS NEAR SOUTH POINT MILL, BERRY STREET, SAN FRANCISCO, CAL. Office, 606 Montgomery street, Room 16, San Francisco.

Are Prepared, with Superior Machinery, to Manufacture and Build all kinds of Bridges on Smith's, Howe's, and other Improved Plans. Framing of all kinds done by Machinery.

The Smith Bridges have been thoroughly tested in the East and this Coast for Three Years, and wherever tried have proved superior to any other Bridge in the following points: Being built of wood entirely, they are not affected by change of temperature. The timber used is placed so directly in the line of strain, that less material is required to support the same load. It is not perceptibly affected by shrinkage. It is the most Economical Bridge built. It is adapted to any practicable LENGTH OF SPAN. Plans, Specifications and Terms will be sent to any County, Township or Person wishing to build a Bridge, and no charge made unless the Plan is used. For all Public Bridges the Plan will always be open to competition. Smith's celebrated CAST IRON PIER, economical, and adapted to heavy currents, built at low rates.

A New Threshing Engine.

It has been rumored for some months past that a firm in this city were to bring out a new threshing engine this season which for simplicity and economy was to eclipse any previous efforts in that direction. A sample engine has arrived and is now on exhibition at Treadwell & Co.'s; and we have the pleasure this week of laying before our readers a partial description of its merits and the two accompanying illustrations showing a side and end view in perspective.

It is an "Improved Hoadley", and is manufactured by the same parties East who have hitherto made the old Hoadley engine so well known throughout the country.

The agents claim that with an engine weighing 1,000 lbs. less, and consuming fifty per cent. less fuel, they are able to accomplish a greater amount of work than with the old style 8x12 engine.

This result is accomplished by means of several radical changes. Mr. Hoadley, who is considered one of the most thorough engineers in the United States, seems to have taken an entirely new departure in the construction of his present engine. A noticeable feature, which at once strikes the eye on seeing the engine, is the absence of the old governor with its attending steam pipes and throttle valves, all of which tended materially to decrease the pressure of the steam on its way from the boiler to the cylinder, by condensation and what is termed "wire drawing." In the new engine the cylinder and valve chest are surrounded by a steam jacket. The valve is of the style known as the "balanced piston," and, through the eccentric, is acted upon directly by a governor of peculiar but simple construction placed on the crank shaft and entirely within the run of the drive wheel. It controls the engine steadily, and can be easily set to vary the speed, and should it from any cause get out of order the engine will at once stop.

The valve is constantly surrounded by steam at full boiler pressure consequently, the initial pressure on the steam piston is very nearly equal to the pressure in the boiler. The regulator acts by cutting off shorter or following the piston at greater length as the case may require, the initial pressure being the same under a heavy or light load. This idea of making an automatic variable cut off with an ordinary slide valve and the use of but one eccentric is a valuable invention. In a trial which took place on the evening of the 23rd inst. in Fremont street, near the corner of Market, the efficiency of the new spark-arrester, which is placed on all these engines, was thoroughly tested.

The spark is so constructed as to obviate the necessity of any hood or wire screen being used, leaving the top always open and free for the escape of the gases of combustion, thereby in no manner impeding the draught. Steam being raised to one hundred pounds, a powerful brake was applied to the fly wheel. The valve was thrown wide open, and with the ex-

haust due from an engine of that size working at full 30-horse power, not a spark was seen issuing from the pipe, although fuel of the lightest kind (shavings and wood) was used and well stirred during the trial. The test seemed to be thorough and most satisfactory.

placed between it and the boiler, be at once removed without the necessity of blowing off the steam. The running gear is of the most approved construction, the wheels being built in the strongest manner possible with very wide and heavy tires; the old style of attaching

THE NEW STYLE "HOADLEY" VARIABLE CUT-OFF 15 HORSE-POWER PORTABLE ENGINE.

The fire box is steel throughout, while the shell is of very heavy iron and double riveted. Ample facilities are offered for cleaning by hand-hole plates, mud plugs in each corner of

the hind axle to the fire box by means of flanges has been discarded in favor of the more expensive bent axle. In a word, the engine seems to be well and faithfully made; and anyone in-

the same period last year. Stocks of West Coast produce were estimated at 19,574 tons against 23,370 tons on the 1st of March. There does not seem to be much encouragement to ship copper during the present depressed state of the market.

MR. A. S. HALLIDIE, who recently resigned from the Board of Regents of the State University, is nevertheless, still one of that body. The President of the Mechanics' Institute is *ex officio* a member of the Board of Regents, and as Mr. Hallidie intended resigning his position in the Institute, and his presence was required in the Board of Regents, he was appointed a special Regent at the request of Governor Booth, in anticipation of his resignation as President of the Institute. But being unprepared to remain in the Institute as President, he resigned his special appointment which he had received in place of Mr. Butterworth, and is now a Regent *ex officio* as before. Mr. J. M. Hamilton, Master of the State Grange, has received the appointment and filed Mr. Butterworth's place, which Mr. Hallidie held under the special appointment.

STRAW BURNING BOILERS.—We are happy to learn that the straw-burning boiler, patented through our Agency, by H. W. Rice, of Haywood, are meeting with good success, and are proved to be of greater value than has been claimed for them. This patent relates to a novel way of burning fuel in a long, tubular furnace, and returning the bent through the entire length of the boiler, giving a complete combustion, and making them not only desirable in the saving of fuel, but also in

being perfectly safe in the harvest-field. Two of these machines operated successfully last season in the San Joaquin, Livermore, Salinas and San José valleys.

GILPIN COUNTY, Colorado, furnished \$204,588 in bullion, in March, of which \$116,000 was gold, and \$88,588.37 was silver.

Another quicksilver mine has been discovered one mile from Stower's ranch, about four miles from Jackson, Amador county.

CORRESPONDENCE.

Cremation and Interment in Regard to the Cycle-Metamorphosis of Organic Bodies.

[Written by Dr. L. THIES.]

Cremation.

This burning of dead human bodies, was a usage among some ancient nations and is yet in use among some few unchristianized, or rather heathen, populations. It was and is still there the belief, to send the bodies of the deceased by the action of the sacred fire, the trusted messenger of nearly all their sacrifices, living or dead, bodily and directly to the gods and therefore directly to the place of their future abode. Bodies of criminals, of hated foes and infected were thrown on the field and served as food for ravens, vultures, etc.

Interment

Of the bodies is also a very ancient usage; among some nations we find graves, bones and other relics in graves and caves many centuries old. In all cases it was more or less a desire of the bereaved relations or people, to know and mark the resting place of the beloved or mighty one, to visit the now sacred place, to cherish the remembrance and love and nurse the soil which covered the form of the body, man, woman, child, or often only a pest animal.

In the more recent time of the Christian Era, the burning of the bodies was gradually abandoned for burying. The principal reason, therefore, may be found in the implicit belief and adherence to the bible and its very words, which promise to its believers a day of judgment, when they will be awakened, and some of them perhaps astonished, by the sound of tremendous trumpet blast, which will call them up from their so long occupied resting place for the last and general meeting.

This Faith,

In the words, is perhaps one of the reasons which create opposition to the seemingly entire destruction of the body by fire. Added to this belief also are the instinctive love and affection, which in old times, as well as now, built monuments over the resting place of the body.

We live in an age when all the words of tradition, no matter from which source, are and will be in the end powerless against this flood of enlightenment which burst the clouds of darkness in which we were living.

The fertile brain of man goes always onward and figures no longer with fiction; it defines the truth by the slow logical means acquired by facts, gathering these as it moves along, and shows the fallacy of those doctrines, which once it was a crime to doubt. Above all the sciences is the

Science of Chemistry.

The never resting one; and it is this science alone which teaches and learns, and learning finds new stations to locate a new marked era for and in the progress of the scientific world.

To our times were the greatest strides of this science reserved; no more a single science, but associated and combined with the new progressing arts and mechanical contrivances, not fruitless in its researches, not egotistical, following the trail for individual benefit; but disclosing before our eyes and senses every day new experiences, new facts, and opening the widest field for appliances in commerce and agriculture, a benefit for each and all. With reasons and proofs, it narrates to us the hitherto unreadable hieroglyphics of the creation, the composition of bodies; nay, it tells us with unsparing certainty the nature of gases which surround our terrestrial globe millions of miles distant from our own, defines to our astonished ears the laws of all the creation on our globe, and last, but not least, proves that the process of resurrection is going on. For this bright light of absolute truth, we thank the genius of the eminent chemist, Liebig.

But may we ask, what has this to do with cremation and interment? His researches and others prove to us that metamorphosis of matter, which our organic bodies, animal as well as vegetables, are subjected to, end at last in one and the same result, no matter whether the seeming destruction is performed by slow combustion, (decay, oxidation,) as in the case of interment, or by actual, perfect and rapid combustion, as is done by this proposed cremation. The processes give back to the inorganic world what was taken from it by the action of life, for the building and the keeping of the body and in turn expelled again, as long as life lasted.

We have here only to do with the matter, and leave the power of life, soul or spirit, as a subject of belief, to the doctrines of the church.

Inorganic and Organic Creation.

But matter is nothing of belief; it belongs to realities, and is subject to proof. We divide this matter into inorganic and organic creation. The first comprises the foundation of our globe, — a body without inhabited life, lasting without apparent alteration, centuries after centuries, produced by inorganic forces, by chemical affinity and cohesion, existing by themselves, and as passive tools of the totality.

The principal bodies, and those which come under contemplation in regard to the above metamorphosis, are the atomistic, endowed with

the organs of life or activity; and these again we divide into animal and vegetable bodies. Composed of more or less organs, and forming a relatively independent individual, they exist for a certain time, not only by physical and chemical laws, but also by the vigor of life, more or less clear to our senses.

Their being is subject to constant alteration of substance; arising, growing and decaying are the cycle they perform. They die, but other similar beings take their place, only to go through the same procedure. The exchange which perpetually gives new material to them and takes away the expelled, is, next to the life power, their chief condition for existence. In these regards, they are the counterpart of the before named inorganic bodies, and show by comparison more distinctly opposition to, than harmony with these lifeless masses; and yet they consist, in the principal composition of their chemical ingredients of well known inorganic elements, principally water and mineral salts, joined to a singular organic matter, without which there is never an appearance of life. The difference is, therefore, not in the simple constituents themselves; these are identical, but it is the adaptation of a few elements to this harmonious structure of the organized body, and this is the condition of existence.

Decay.

A principal faculty is absorption of oxygen to saturation and, therefore, aptness for combustion and final redistribution of the accumulated inorganic elements to their sources. Water, ammonia, carbon, etc., go back, whence they came, to the atmospheres. Sulphur, phosphorus, iron and alkalis are left in the residue, the ash; and are again ready to be used anew for building up of new structures in organic bodies.

We see, therefore, no matter which was the destroying agent, the same results appear from the slow decay, or the rapid combustion; it is in such way destruction of the mold, but destruction of the matter itself is an impossibility. The one is slowly preparing for future use, the other is ready with the same material, in a rapid way.

Let us see now how this newly prepared raw material passes through the metamorphosis to its starting point.

By aid of root and leaves, the plant absorbs from soil, water and atmosphere, these immense warehouses of inorganic matter, all necessary elements for construction, keeping and developing in form of carbon, water, ammonia and mineral salts. In the organs of the leaves, it absorbs by the assistance of sunlight, the carbon, etc., from the atmosphere, retains the carbon and returns the oxygen; it forms with the carbon, and with the help of water, ammonia, new combinations; builds with these as material, fiber on fiber and vessel on vessel; fills these again with juice and sap, inorganic in origin, but now organic, with wonderful harmony and fresh from oxygen, so long as life lasts — a laboratory in itself working and creating; unknown in its actions and its working process, a mystery like its principle, the life.

Materials of Growth.

What we know and have to contemplate, is the result of this co-working of life and body, and this is ours by "encheiresis nature," and open for our researches, giving to us the Ariadne thread in hand to follow through the labyrinth of errors back to the beginning, with unerring certainty. The perfect counterpart of the plants is the animal system in its actions. It needs for its structure, as a condition of sustaining its life, the already formed organic substances; it has not the faculty to extract and form from simple organic elements those organic substances which it needs for sustenance. Only in vegetables are the required funds for its structure and life, and only there it finds the sources in form of carbon, hydrogen, fat and albumen, either directly, or indirectly by devouring other animals, which were themselves living on plants.

But besides these, it needs also some inorganic matter and finds this in the water and mineral salts, partly prepared in the plants, partly directly in the organic creation. Among these, the oxygen, above all, is a condition for the functions of its body and preserving of life. Like the leaves of the plants, the lungs are here the never resting feeders on the atmosphere, acting in an opposite manner to the leaves, by keeping the oxygen and expelling the carbon. The oxygen penetrates through the surface of the respiratory organs and comes in contact with blood and fluids in the vessels of the body, distributed and penetrating not alone the animal structure, but also acting a principal part in the nutritive substances, which modified by digestive process are divided through the whole body. And here already this organic combined substance undergoes a gradual oxidation and passes over from simple to higher and more oxygenated combinations, till they are saturated and expelled and leave their former combined, but now separated inorganic elements, to the warehouse of nature; ready again to be used for new structures and metamorphoses.

This is the cycle of the household in the nature and clearly and distinctly do we see the boundaries, conditions and laws of not alone our existence, but also those of more or less life-endowed creation; and these are as significant of the end and beginning. No truer words than from dust to dust on to eternity!

Is Cremation Preferable to Interment?

And by what reason? The answer must be: Most positively! Slow combustion, or decay, by slow absorbing of oxygen, as by interment,

produces and gives in a slow way to the inorganic creation, what life-endowed energy took and used from there, for building and constructing, in a space of a few years. It radiates the elements, but in an imperfect way, holding back essential parts and retarding by this the recreation of new bodies, impoverishing, nay robbing, the store-house of nature of a part of their due. It does still worse: made from simple and originally healthy elements, the structure of plant and animal is a model of beauty and health, an edifice appropriate and worthy for its inhabiting soul, pure and good as nature itself. But as impoverished, poor, or poisoned soil will starve, cripple and poison the plant and bring it to an early decay, so will thus, as an unhealthy poisonous or adulterated food, vice, bad habits, abuse of body create more or less diseases and sickness in the animal world; and more, in our human body, as in other animals, it poisons the body and makes from this temple of purity a miserable wreck, often deserving this worthy house of a miserable soul; often innocently, and then a loud lament and accusation from the guilty one arises. Premature decay is the result, and its results, again, are the undestroyed modified and spreading germs, inoculating with an increased progress new victims. Plague and pest reap with insidious interest from the capital of negligence and improvidence.

All this would be avoided by the rapid and actual combustion, which dissects the constituents of the body into its original elements, but rapidly and perfectly, and also purifies and disinfects; it destroys the organic germs, and gives the inorganic elements back, pure and healthy, for further healthy structures.

In the century in which we live — a century of intelligence and research, but also often of mercenary principles — we may expect much opposition to this proposition of cremation. But there never was a better and more useful proposition made for warm climates, over-crowded countries, cities, and also here for our particular locality, San Francisco, where the influx of foreigners from all parts of the globe is steadily increasing its population, and where, besides, is kept and nursed, in its very heart, the best established and most ingeniously planned breeding place and hot-house for plague; but where it would be, if properly executed, the only remedy against its spreading among that class of inhabitants, who, too improvident or otherwise, do not belong to the proprietors of one or more of the above-named nurseries, and can therefore not afford to live across the bay or further off. For these and their families cremation would be a feasible protection; and it is to be wondered at that the Board of Health did not before this order the cremation of the bodies as well as of the straw and clothe (provided these were not stolen before). The destruction of contagious germs, and, therefore, preventing the spreading of these diseases, would be the result. And in this case cremation should be compulsory by law, at least for those who have died from contagious diseases in public institutions.

Buckeye Mountain.

With last Friday's stage, arrived in Weaver-ville Mr. John Simpson, of Cerro Gordo, Iroquois county, and Mr. J. E. Spencer of San Joaquin, who came here to look at Trinity county. After a week's stay, Mr. Simpson informs us that he came here for a specific purpose, had examined the matter thoroughly and was more than satisfied with the result of his examination. He says that Trinity is at once the most extensive and evidently the richest gravel mining section on the Pacific Slope, and that the facilities for working the immense gravel deposit found here are unsurpassed. Plenty of water (by going after it), plenty of gravel, plenty of pressure, and plenty of outlet, and, we might add, plenty of gold. What more could capital seeking investment in hydraulic mines desire? Certainly nothing more.

Feeling confident that the investment will prove one of the most productive and certain that can be made, Mr. Simpson has bonded the Atkins & Lowden property, in the interests of the company he represents. This property consists of a Stuart Fork water-right and ditch, and a large area of mining land on Buckeye mountain. Mr. Simpson says that operations on this property will commence at farthest by the middle of May and that in six weeks from that time a portion of the waters of Stuart Fork will be used in washing gravel in the great Buckeye range. It is the intention of the company to dig a ditch, on the upper line, eight feet on top, five feet on bottom and three and a half feet deep, and have water in it by the first day of July. After that they propose to construct a second ditch of equal dimensions 200 feet lower. The reason for two ditches is that either will be high enough to cover the mines, and that it will be cheaper to dig two small ditches than one very large one, on account of the mountain rising so abruptly; also that the danger from slides and breaks is much less on smaller ditches.

Want of space at the late hour we were made acquainted with this matter forbids a more extensive review of the enterprise at this time. Men experienced in gravel mining need but to look at Trinity county to know that the inducements for investments in ditch and mining enterprises within her borders are superior to those presented by any other section. The Weaver-ville Ditch and Hydraulic Mining Company and the one referred to in this article — not yet incorporated — are but the forerunners of others which will be formed and operating in Trinity within the next twelve months. — *Trinity Jour.*

The Georgia Gold Fields.

The following, taken from a letter just received in this city from the gold fields of Georgia, written by the celebrated mineralogist, Dr. M. F. Stephenson, formerly assayer to the United States Mint, will be read with interest:

The Chestatee rises in the Appalachian mountains of Georgia, in Lumpkin county, and flows southward through one of the most picturesque and charming countries in America, and falls into the Chattahoochee river in Hall county; then aways on to the Gulf of Mexico. The Chattahoochee is so called, in the Cherokee language, from rubia being found in its sands. It has become historical as being the western base of "De Soto's conquering march" through the Seminole, Creek and Cherokee nations of Indians. All along this route, from St. Augustine in Florida to the Nacoochee Valley, are found numerous relics of his fortifications, his battles and explorations for gold, the last being his chief object.

This Chestatee, as well as the Chattahoochee, traverses the gold belt for a distance of 20 or 30 miles, mostly at right angles to the strata or trend of the gold veins, which necessarily has produced rich and extensive deposits in the creeks and river beds, as well as places on the table lands and hill sides. The Chestatee, from its mouth to the junction with the Tennessee, above Dahlonega, is vastly rich, but has not been worked, excepting the shoals, which yielded large profits to the operator. Several companies have been organized heretofore to turn this river by canals, and one by a wooden flume for some 10 or 20 miles, but this war prevented a successful development of their plans. Two companies are now engaged in preparation to work the river bed, one from Ohio, under the control of Colonel Price, who is cutting a canal and tunneling through a ridge so far as to bare and make available three miles of gold deposits. This canal is near its mouth. The other is constructed by J. K. Bartlett, of Boston, who has engrossed nearly ten miles of the river. Both are practical men, and have not only the capital, but the skill and determination of purpose to carry it out to completion. All the workings, in years gone by, in the shoal water, yielded from \$1 to \$10 per square yard, which, if properly worked, with energy, as the above parties indicate, will give millions annually to the treasury of the country.

The vast mineral wealth of this region, heretofore scarcely known, is beginning to be appreciated. Capital and enterprise from the North and West are coming in, people of the States are excited, and already, on every hand, evidence is increasing of the practicability of gold mining, which bids fair to exceed the most flattering productions of California. Another company from Ohio, under the supervision of Colonel Hand, of Cleveland, is preparing to work the extensive placers controlled by the charter of the old Yahoala mining company, around Dahlonega, upon the canals and mills of which the former company expended nearly half a million dollars. When the rich and extensive gold field is put under the hydraulic process, the yield will be enormous, and the same process will expose hundreds of rich veins which have now no outcrop. Of their success, no practical miner here has any doubt. The capital necessary to work many of the more favorable sections of the river will be comparatively small, and many veins found without any expense. It was thus with the "Boly-Flains vein," which is now being developed by Mr. Bartlett, of Boston.

This vein is in hornblende gneiss, and when first opened yielded the richest ore ever worked in the world. Its most singular characteristics are that it is in the oldest formation, and disproves the absurd theory of Lord Murchison, Lyell, Dana and other authors, that gold was brought to the surface only a short period before the appearance of man on earth. We have two other mines which prove the same, one where the gold is diffused through the oldest granite in paying quantities for miles, and the other in feldspar over a hundred miles from any over-lying rock containing organic remains, proving this mountain ranges to be millions of years older than the Rocky mountain chain, the Alps, the Andes, or Himalaya, where you find vegetable and animal organisms from 10,000 to 16,000 feet above the sea, in the overlying rocks on the mountain sides, incontrovertibly proving that they were elevated above the sea in the Tertiary period, whilst the Appalachian chain was upheaved in the Azoic age.

All we need here is capital and enterprise to develop millions, at one-half the expense of working the mines on the Pacific Coast, in Central and South America, or Australia. Hundreds of rich veins have been worked to the water-level and abandoned long since, for want of capital. — *Boston Advertiser.*

The *Pioche Record* in concluding its mining review of the past week says, we may say that though perhaps there might be more favorable developments, still enough has been shown in the Page & Panaca and Washington & Crook to demonstrate that the lead struck in the Lightner shaft is the true ore-bearing vein of the district, and that depth, or superficial disturbance, does not alter its character. It may be that from cross-heads, or some other wrong head, it may be slightly moved from its course, but still, like the Flag, it is still there, and will yet send forth a stream of bullion that will make Pioche renowned.

MECHANICAL PROGRESS.

A Gravity Elevated Railway.

A merchant in Chicago has recently patented a device for a street railway, dependent upon gravity for the motive power. The *Chicago Tribune* thus describes it: The railway itself consists of a series of inclined tracks, elevated upon a heavy framework of pillars and trestles, upon which the wheels which carry the car travel. The central posts are heavy timbers, 12 inches square, into which are set the cross-joists which support the double tracks on each side. The inner track is set one foot from the post, and the outer is 18 inches from the inner. The tracks are set on beds, two by 14 inches, and are braced to the trestle-work and to each other. The cars do not run on the tracks, but a set of four wheels with grooved edges travel on the half-round rails, and the cars suspended from the axles of these wheels by wire rope. On starting at the highest point of the first section of track, the car is hung about one foot clear of the ground, and, as the sections are one mile long or more, and the grade is about 25 feet to the mile, it is evident that the car would strike the ground within a very short distance. To obviate this a large wheel, five feet in diameter, is placed at the front end of the car, on the side. This wheel is turned by spokes, like a ship's wheel, and the bold pilot of the car occupies a little platform, where he can keep a lookout for passengers and work the machine. As the wheels descend the operator winds up the car a distance corresponding to the vertical fall, by means of his large wheel, and a series of pinion-wheels which turn the shaft to which the supporting rope is attached. The car is thus kept constantly at the same distance from the ground at which it started, and the exertion necessary is not great, owing to the lightness of the car and the leverage obtained by the gearing.

The tracks are arranged with opposite inclination on opposite sides of the posts, so that the cars travel in opposite directions on each side. As above stated, the average length of the inclined sections is one mile, but the road can be extended indefinitely by a simple contrivance. On reaching the lower point the wheels run upon a piece of track which slides vertically in grooves to the height of the original starting point. The trestle work here is again high up, the wheels start on their descent once more, and the journey continues. The car itself is neither raised nor lowered, but the wheel is simply thrown out of gear, and the rope unwinds from the cylinder to be rewound as the wheels again descend. The sets of wheels weigh less than 100 pounds each, and are raised by the descent of a counter weight at each station, where a station-keeper is placed to attend to the changing of wheels from the lower to the upper track. Each car carries ten persons, for each of whom a seat is provided with a sliding door for each seat, and, when they are filled, no more passengers can be carried. The cars weigh about 500 pounds each, and cost from \$75 to \$100. It is thought that the road will not cost over \$2,000 per mile where the incline is not over twenty feet to the mile. This rate of speed, of course, depends upon the amount of the incline, and the weight of the cars and passengers. The full car should have a speed of fifteen miles per hour, with an inclination of twenty-five feet to the mile. They may have more, but the conductor has a brake upon the wheels, and another check in the shape of two obliquely inclined iron rods which will drag along the ground to prevent lateral motion of the car. They can be pressed into the ground by a treadle, and the forward motion thus checked also.

IMPROVED WHEEL FOR VEHICLES.—Upon the end of the axle is formed an axle arm, made octagonal or of other polygonal form. A short cylinder has a hole formed through it of the same shape as the axle arm, and its outer surface forms the journal of the hub. The cylinder is placed upon the middle part of the arm, and upon said arm, upon each side of the cylinder, is placed a flange, made somewhat conical in form, which is secured in place upon said axle arm by a linch pin. A ring, which forms the hub proper, is made with a ring groove to receive the tenons of the spokes, which tenons are separated from each other by thin partitions, which may be V-shaped. The outer edges of the ring have flanges formed upon them, which overlap the edges of the flanges first mentioned. The spokes may be further secured in place by bolts passed through the flanged outer edges of the ring.

AMERICAN LOCOMOTIVES.—An article in *La Bourse*, of St. Petersburg, warmly commends the construction and performance of the American locomotives for burning anthracite coal, recently arrived in that city. The frame, it says, is solid, instead of being of plate, and the character of the cylinders, the manner in which they are adapted to the machine, and the mechanism of all the details which enter into the construction of a locomotive, it pronounces superior to anything of the kind ever seen. It especially notices the immense fire box, about nine feet long, which forms the essential part of the system of heating with anthracite; and the grates formed of several ranges of tubes, one above the other, extending from front to rear in the furnaces, and the circulation of water in these tubes so as to protect the interior walls against the intense heat.

Weight in Machinery.

It is undeniable that the mere inertia of the material of which a machine is made is a most important element, as concerns its strength and durability, and also even more especially its stability when in use. We are here speaking of matters wholly outside of dynamic effects, and with especial reference to the utility of greater weight than is now accorded to many varieties of machinery. An apparatus constructed with a slender frame rigidly bolted in place and stiffened by the careful adjustment of braces will serve its purpose well for a while. But the very rigidity which reduces its vibrations to a point imperceptible will, by the same agency, quickly jar loose its joints, and, in many instances, where steel is used for parts subject to percussion, deteriorate the quality of the metal and prove the remote cause of breakage and loss. Imagine a percussion strain, that, under the conditions just supposed, would prove mischievous, distributed through a larger mass of metal (a dead weight, if one should please to call it so), the effect is deadened, the parts work more smoothly, and greater uniformity in operation and of products is the result. We speak here in general terms, for these remarks apply generally to machinery run by steam or equivalent motive power.

But the advantage of due weight in machinery is not confined to its framing or to merely the static conditions under which such is commonly employed. We know that a light balance wheel run at a high rate of speed may be made to do the work of a heavy one run at a low speed, and as far as regards the founder's bill for the casting, may have the preference. But no balance wheel can be run exactly, or in other words have its axis of motion really and truly coincident with its axis of weight and form. At a moderate or ordinary number of revolutions per minute, this may be practically inappreciable. But increase the ratio of motion and the effect of any inequality, however slight, is manifest. It is on record that a displacement of two pounds of metal in the weighty balance wheel of a down-east cotton factory shook the whole building as the wheel revolved. Not only must balance wheels be as truly poised upon their axis as the best workshop practice will insure, but they should be of such weight that they secure their avowed objects at a moderate motion. Our steam engineers as a rule understand this, and to them we are not particularly speaking; but designers of new machinery, and of the latter a hundred examples are brought forth each day, are more apt to fall into the errors to which we have hastily alluded, and it will be well for the success of such undertakings if, as a rule, weight, combined, of course, with sound judgment as to proper proportions of parts, receives the credit that belongs to it, as a safe and reliable conservator of mechanism in motion.—*Newark Manufacturer.*

SAFETY RAFT.—An extraordinary safety-raft, the invention of Mr. J. A. Fontaine, is about to be presented to the consideration of the French society for saving lives from shipwreck by Admiral La Ronciere le Noury. This raft is described as large enough to support from 400 to 600 persons, as neither encumbering, nor requiring any alteration in the arrangement of vessels, and requiring only a minute or two to inflate and launch it. It is an air-tight tress, with a surface of eighty square metres, inflated in one minute, it is said, from a reservoir fixed in the engine room and always charged with air under a pressure of fifteen atmospheres. When not in use, it is rolled up, and takes no more room than a boat. When inflated it falls over the side of the vessel, against which it is retained by means of ropes till all the persons on board are transferred to the raft. Three strong spars, passing through tubes the whole length of the raft, keep it flat and solid.

IMPROVED MACHINE FOR ASSORTING POTATOES.—This machine consists of long rollers, a hopper, assorting board, and grading chutes, so combined and arranged that the potatoes being shoveled into the hopper at one end and caused to run along the assorting board and the rollers, the smaller potatoes will escape between the roller and assorting board, while the larger ones will be discharged at the end. The distance between the roller or rollers and the assorting board increases from the head toward the tail, and the potatoes escape through the space, varying in size in the same measure, so that they can be separated into two or more grades by suitable partitions in receptacles below. The assorting board is adjustable toward and from the roller, so as to change the grade at will.

An apparatus for planing, tonguing and grooving wood has recently been patented. This invention relates to apparatus for planing true on the face and tonguing and grooving its edges, more particularly applicable in the preparation of flooring in small pieces, which can be continuously fed and discharged. The table of the machine consists of an endless chain of plated links, traveling between guides, and provided with edge dogs for holding the pieces which are passed between revolving edge cutters for grooving and tonguing, and under a planing disc mounted on a vertical spindle, at the side of the wood. The wood is released by the hand of the chain over the chain wheel and the withdrawal of the back dog.

COLORING PLASTER.—A delicate cream color may be given to plaster by mixing with it a little yellow ochre.

SCIENTIFIC PROGRESS.

Reclaiming the Desert Places.

The explorations of the French engineers have proved that the surface of the great Desert of Sahara is below the level of the ocean, in fact that it is the bottom of an ancient fresh water lake, which has dried up by gradual changes in the surrounding levels, the streams which once supplied it now going directly to the ocean. It has been therefore suggested to change this desert back into a lake, and in this way to alter the whole climate of that country. This would, of course, create a moist atmosphere in place of the burning, hot, dusty whirlwinds which are the curse of that region. There are, however, no rivers to be turned into the basin; and the artesian wells, successfully bored by the French, which create oases in the desert round them, give too insignificant a supply for such a great purpose. It has, therefore, been proposed to make a channel to the ocean, and lead the ocean water into the desert; but in consequence of the vigorous evaporation in that latitude, the water, when once spread out over any considerable surface, would probably disappear as quickly as even the largest sized canal could pour it in.

The Caspian sea, which is situated below the surface of the ocean, evaporates the waters of the Volga as rapidly as that colossal river, the largest in Europe, is able to pour them in. The water of the Volga is fresh, containing only a small percentage of salts; but this small amount of salt remains in the Caspian sea, while pure water only is abstracted by evaporation; thus the sea is very salt, and becomes more so every year. If now the collection of fresh water in a closed lake, from which there is no exit but evaporation, ends in making a salt lake in a cold climate, the introduction of sea water to form such a lake under a tropical sun, as proposed for Sahara, would result in making a huge salt pan, which would gradually fill up with solid salt, till it reached the level of the supplying ocean; and we should only have transformed the dry sandy plains of the desert into dry salt plains, and which of the two would be the worst is a matter for discussion.

We think that a continuation of the French system of boring artesian wells in all available spots is the best method of reclaiming the desert. Many of these wells have already been completed; and it is indeed touching to read the description of the joy and religious enthusiasm of the natives when they see, for the first time, a bountiful supply of fresh, cool water poured forth from the bowels of the earth in spots where never before was water seen for miles around. The creation of an oasis in the desert is the immediate consequence of each well; and in the course of years the dreadful Sahara may be so profusely clothed with artificial oases that most of its terrors will have passed away.

As to our American deserts, recent explorations and surveys of the great desert of the Colorado river have shown also that it was the bottom of a lake which had dried up, because the river has cut its channel in the rocks, through which it flows to the ocean, so low down (from 4,000 to 6,000 ft.) that the lakes, formerly connected with and supplied by the river, lie now far above its present level. These lakes have for centuries collected at their bottoms the deposits of the Colorado river; and the now exposed surface consists, therefore, of an alluvial soil of extreme fertility (containing potash, soda, lime and phosphates), which, however, cannot produce any crops on account of the total absence of moisture. The whole region is, indeed, a desert, like that of Sahara; and, like the latter, a portion of it lies below the surface of the ocean, as proved by barometric observations. It is believed that the waters of the Gulf of California formerly extended some 175 miles further inland than they do now; that subsequently the delta deposits of the Colorado (which were enormous, considering the deep channel which it has hollowed out for itself) formed a dam in the sea 175 miles from the shore, finally enclosing a sheet of water, which then dried up and now forms that part of the desert which is lower than the ocean.

It is proposed to lead the waters of the ocean into this low portion, so as to inundate it, and increase the atmospheric moisture in that region; and it appears that the plan is feasible, at a comparatively small cost; but one objection is that then a large portion, some 30,000 or 40,000 square miles, which otherwise might be made productive, would be sacrificed; and this plan is also open to the same objection as that of inundating the Sahara with sea water: it would end in the creation of an enormous salt pan. We prefer the other plan which has been suggested, irrigation from the upper part of the Colorado river, which, to be sure, would cost much more, but would reclaim all the highlands of this desert. The geologist of Williamson's expedition, Mr. W. P. Blake, points out that, by cutting a canal or deepening a certain small river low enough, so that the water from the Colorado could enter it at all seasons of the year, a constant and plentiful supply of water can be furnished to the interior of the desert and used for irrigation, while the surplus will fill the lower portions with fresh water, find its exit to the Gulf by a pass to be constructed, and also establish navigation from the Gulf of California to the interior of the great lake. A thorough survey is needed, and also experiments in boring artesian wells;

which, without doubt, would here be as successful as in the African desert, as is indicated by indisputable geological evidences.—*Scientific American.*

UNDERGROUND TEMPERATURE.—At a meeting of the physical science section of the British Association, Professor Everett read the report of the committee on underground temperatures. It is well known that the temperature of the earth increases, as a general rule, the deeper instruments can be sent below the earth's surface, and the committee has been at work for some years collecting accurate information on the subject by trying experiments in wells, mines and tunnels. The report told how temperatures had been observed in the deep well at St. Denis, near Paris, also in the Kentish Town well, where, at a depth of 1,000 feet, a temperature of 57 degrees Fahrenheit had been observed. In the Sub-Wealden here, near Battle, Sussex, a temperature of 68½ degrees had been observed at a depth of 168 feet, the temperature of the surface springs being then 51 degrees. Preparations are being made to observe temperatures in Mont Comis tunnel, also in the St. Gothard tunnel. The latter will be larger and deeper than the Mont Comis tunnel; it is already begun; and the mountains have been pierced about 300 metres at each end of the tunnel. Experiments on the thermal conductivity of rock would give results, said the report, which would much aid in researches on underground temperatures.—Mr. Sissons asked to what extent the temperature of the earth increased as greater depths were reached?—Professor Everett said that the temperature increased, but at different rates in different places; in some places it increases one degree Fahrenheit in every 100 feet, and in others as much as one degree in every 50 feet. The President said that there were two leading sources of error in experiments and researches of this nature; first, the friction of the boring apparatus was liable to raise the temperature temporarily; secondly, the thermometer had frequently to be sunk into water in which liquid struts are always mixing more or less, so as to affect the reliability of the indications.

TREATING SULPHUR ORES.—Messrs. Croll and Dalglairns, London, suggest improvements in the mode of treatment of sulphur ores, for the separation of the foreign matters and impurities, found so largely combined therewith, without the agency of heat, as customarily employed, whereby the pure sulphur itself is to a considerable extent dissipated and carried off to waste, besides generating a nuisance in the locality by the escape of noxious volatile emanations. For this purpose the purer portions of the sulphur ore are to be separated from such portions as are most debased by admixture with foreign matters and impurities; and these mixed or impurer parts, having been thoroughly comminuted and reduced to a state of fine pulverisation, are to be treated with water, and agitated or otherwise manipulated, so as to effect a complete separation of all the different ingredients, according to their various specific gravities, within a suitable reservoir or receptacle, whereby the sulphur is eliminated from the impurities. Muriatic or other acids may be employed to combine with the foreign matters and aid the separation; and the washed particles, according to their densities, may be drawn off and removed at different points.

A NEW ALKALOID FROM MORPHIA.—A new substance has been prepared, by G. Nadler, by the action of an ammoniacal solution of cupric oxide on morphia. Its chloride is of a brilliant white color, and is easily soluble in hot water, in which the ammonia throws down an amorphous precipitate, that remains unchanged in the air in the moist state. With concentrated sulphuric acid, it becomes of an intensely green color. From the potash solution, when boiled, the alkaloid separates in scales having the luster of silver. It is, moreover, distinguished from morphia by its trifling solubility of its sulphate, and from apomorphia by its stability in moist air.

EXPERIMENTS made to test the vitality of frogs, in relation to the fabulous accounts of frogs found embedded in rock in deep workings of mines, in England and elsewhere, showed that frogs frozen up in blocks of ice for over eight hours were alive and breathing normally as soon as they were thawed loose from the ice.

PROFESSOR DONDERS shows that the time occupied in the transmission of a sensation through the eye to the brain, the formation of a judgment, and the transmission of a volition from brain to hand is .15 of a second; but when the ear is the receiving organ the time required is only .09 of a second.

SEVEN minor planets have been discovered during 1873, all in our own country. Four of these were detected by Prof. Watson, of Ann Arbor; three by Dr. Peters, of Clinton, New York. Seven comets were discovered during the year, all in Europe.

An inventor has perfected and patented a process by which raw hides can be utilized for harness, helting, and in many other ways without the process of tanning. His claims in favor of it are greater durability and cheapness.

The velocity of sounds in different gases is found to be inversely proportional to the square roots of the molecular weights.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

California.

AMADOR COUNTY.

ANOTHER QUICKSILVER DISCOVERY.—*Dispatch*, April 25: Another quicksilver ledge has just been discovered, within the past few days, about one mile from Stower's ranch and about four miles from Jackson. Of course the extent or richness of the mine is not yet positively known, but sufficient prospecting has been done to prove that the ledge is over six feet wide, and if it proves to be as rich and extensive as the present indications warrant us in believing, it will be one of the most valuable mines that has yet been discovered in this section of the State. The discovery has created quite a mercurial stir among our people, and a number of claims have already been taken up in the immediate vicinity.

RICHER THAN EVER.—The Amador quicksilver mine still continues to get richer and better as the work of development progresses. The ledge is now about three and a half feet wide, at the depth of eight feet, and the rock is richer than ever.

HEAVY STRIKE.—*Ledger*, April 25: We have just learned that very valuable diggings have been discovered near Volcano, and not far from the Marklee mine. We were unable to learn whether the discovery was in a gulch or on a hill, but the claim is said to be marvelously rich in heavy coarse gold, one piece having been found among a host of smaller ones, of the value of \$250. The fortunate discoverers are Messrs. Rogers & Co., the discoverers and owners of the Rodgers quartz lode in the same neighborhood.

Prospecting along the gravel range of hills north and east of the Mountain Spring House, is progressing favorably; a large amount of ground has been located for mining purposes; a number of tunnels begun, and as work advances, very flattering prospects are obtained. Present appearances indicate that this vicinity will prove, ere long, to be a very valuable mining neighborhood.

Miners and prospecting, we are informed, is being vigorously prosecuted in the vicinity of the Amador discovery, with some very fair additional prospects. Mr. A. Caminetti, of Jackson, has located an extension on the south of the Amador claims, and as far as labor has been expended, very rich float ore has been obtained. A mining district has been established, and on Monday last a district Recorder was duly elected. A large number of miners will be engaged in thoroughly prospecting the district and whose labor may result in valuable mineral discoveries.

CALAVERAS COUNTY.

RETURNS FROM SAN BRUNO—SIXTY POUNDS OF GOLD.—*Chronicle*, April 25: At different times for several weeks past, we have detailed operations at the San Bruno mine, at Mosquito gulch, and ventured the opinion that when the rock taken from it was crushed, we should be able to chronicle the largest clean-up ever made in the upper country. The result more than verifies all our prognostications respecting the mine, and places it among the foremost in the county, if not the peer of any in the State. Two hundred and twenty tons of rock yielded \$12,200, an average of \$55.50 per ton. When it is considered that the ore was unassorted, taken just as it was mined from the ledge, a proper appreciation of the remarkable yield can be obtained. The lower tunnel is now run in the pay chute a distance of 125 feet, with no indication of reaching the terminus of the rich rock, with an opportunity of stopping to the height of 140 feet in the same character of ore.

WEST POINT DISTRICT.—The dump of the Zacatero is rapidly accumulating large quantities of excellent ore, from the south level, which has somewhat improved in richness. No stopping will be done until the new mill is near completion. The temporary improvements of the Pascoe mine are complete. The texture of the quartz resembles that of the Idaho mine near Grass valley. The new discovery on the Woodhouse is gaining in proportions. Some 40 tons of high-grade ore on the dump. The water in Stevenson & Co.'s mine drove out the miners. The mine will probably be idle for some time, as the machinery and pumps are insufficient. The ore on the dump looks well and shows free gold.

EL DORADO COUNTY.

THE ROSE.—*Republican*, April 23: Work is being vigorously prosecuted on this ledge. The south shaft is down 100 ft. and a drift is now being run east. The last crushing of rock (90 tons) went \$48 to the ton, and there are many hundred tons of it in sight.

THE GROSS.—There are now out 40 tons of rock that assays \$600 to the ton, besides a large amount of low grade rock that would pay well to mill on the ground. The mine is situated in a difficult place to get the rock to any of our mills, having to be packed on mules, but a number of tons have been got out in this way, and have paid as high as from four to five hundred dollars per ton.

KERN COUNTY.

Courier, April 23: Several of the mines in this county seem to be working very prosperously for the owners. The old mill at the Blue Lead, Kernville, is running night and day; the indi-

cations in the Havilah tunnel are of a very pleasing character, and the Long Tom mine has about completed its lower level, developing the richest body of ore ever struck in the mine, which is now ready for stopping out.

LAKE COUNTY.

QUICKSILVER.—*See*, April 23: John R. Taylor found a few days since rich specimens of cinabar somewhere on the north fork of Cache creek, ten miles below Bartlett Springs.

SILVER MINE.—Work has been vigorously prosecuted on the old Snisnn mine, northeast of the lake, within the last ten days by a company organized at Upper Lake. They are working the mine for quicksilver.

NAPA COUNTY.

QUICKSILVER.—*Reporter*, April 25: The Manhattan has shipped through here thirty-five flasks of quicksilver to Virginia city this week, and the Reed mine eighty, to Sacramento.

NEVADA COUNTY.

COPPER.—*Union*, April 22: The San Francisco Copper Mining Company, location of works near Spencerville, in this county, shipped yesterday to San Francisco 3 tons of copper matte. This copper mine is bound to prove a great success under the intelligent and energetic management of Mr. G. P. Deethin. The lead is 74 ft. wide, and contains about 8 per cent. of copper. The company will soon incorporate, and will soon also put up a larger furnace than is now used.

MAONETA.—*Tidings*, April 25: One hundred tons of ore taken from the larger ledge of the two in this mine—not considered the best—were crushed not long since and the result, in the shape of gold bullion worth nearly \$2,000, was to be seen at Findley's bank early this week. This was exclusive of the sulphurets, which are known to be rich. This is good paying ore, but it is thought that it can be made to pay better in a mill provided with pans, and a lot of 100 tons is soon to be put through the Empire mill, which is more complete in its reducing capacity.

CALIFORNIA CONSOLIDATED.—This company now own and work the old Gold Tunnel property, one of the oldest gold mines in the State, and the Illinois and California mine, on Deer creek, near Nevada City. They have 6,900 ft. on the ledge; own two mills and a fine hoisting works; are working at present about 40 men, which force will be increased as soon as the new mill is running.

PLUMAS COUNTY.

THE NEW YORK MILL.—*National*, April 18: Mr. M. B. Bransford, of Crescent Mills, informs us that Superintendent Smith has received instructions to remove the New York mill to the mouth of Dixon cañon, where it will be used to crush rock from the Green Mountain ledge. The work will be commenced immediately.

TUOLUMNE COUNTY.

MANGANESE.—*Stockton Independent*, April 25: Some time ago, about 100 tons of the mixture of iron and manganese, found in Tuolumne county, were sent forward to Baltimore for reduction and test, but the result has not, so far as we are aware, been made generally known. That it amounted to sufficient to warrant another trial of the material is apparent from the fact that another lot is to be sent forward to the same destination. Last Saturday, 17 car-loads, or about 170 tons, were landed at the water front for shipment to San Francisco, there to be re-shipped to Baltimore. The lot is consigned to Kruse & Enler. The proportions of iron and other metals the material contains, we have no means of knowing.

RICH POCKETS.—*Democrat*, April 25: We are informed that Blas Radowich & Co., Austrian miners, found and took out two rich pockets in Bald mountain this week. Also, that N. & P. Bauli have found good pay in their claim, getting \$5 to a pan. Bald mountain has yielded a large amount of gold and is hardly prospected yet.

THE CRAIG CLAIM ON SULLIVAN'S DRY ARROYA, is yielding better and better; it has got to 6 ounces a day. And yet there are those who say our mines are worked out.

Nevada.

WASHOE DISTRICT.

SIERRA NEVADA.—*Gold Hill News*, April 23: The new shaft is down 370 feet, the bottom in good sinking ground. The drain tunnel to connect with the shaft 160 feet from the surface was connected with the shaft this morning. The heavy stone foundation with anchor bolts for the machinery is being completed as fast as the nature of the work will allow. The sluice tunnel will be completed by to-morrow, and as soon as the necessary material can be got on the ground the hydraulic works will be erected and the sluicing commenced. There is no change to report of the ore producing section of the mine. Daily yield, 65 tons of ore. This ore is crushed at the company's mill, which is kept steadily running.

CONSOLIDATED VIRGINIA.—The main shaft is completed and timbered to the 1,500-foot level, and a sump is being sunk 25 feet below the level. As soon as the sump is finished, opening the 1,500-foot station will be commenced. The main south drift from the shaft, on the 1,400-foot level, is still pushed ahead to connect with the north drift on the same level from the north winze. This connection when completed will give a fine circulation of pure air and facilitate prospecting operations. The east cross-cut, on the 1,400-foot level, from the north winze, has penetrated the ore body 51 feet, the face still in solid ore of a fine quality. The heat becoming so intense this cross-cut has been discontinued until better ventilation is secured. The ore breasts on the 1,200 and

1,300-foot levels are all looking and yielding splendidly as usual. The mills are all running and the prospects of the mine grow brighter every day.

SUTRO.—Owing to the tapping of a large body of water the company have been compelled to cease the sinking of their shaft. Having secured the privilege, they have decided to extend the old Utah tunnel to their ledge, and thus cut it about 100 feet below the bottom of their shaft, or 260 feet below the surface, draining the water entirely and allowing them to work their mine to the best possible advantage and develop the excellent prospects already obtained by their shaft. This tunnel is already in 550 feet, and less than 700 feet extension will carry it into the Sutro ledge. Clearing out the tunnel was commenced this morning, under the supervision of Samuel Owen. This will take about three days, when the work of extension will be commenced.

HALE & NOKONOS.—The west cross-cut from the main north drift, on the 1,300-ft. level, is in 40 feet, passing during the week through alternate strata of clay, quartz and porphyry, with occasional stringers of ore five and six inches in width, that will assay \$40 or \$50 per ton.

SUTRO TUNNEL.—Header of main tunnel to-day in 5,821 feet, with the face in good blasting ground. Shaft No. 2 was completed last week to the tunnel level, a depth of 1,040 feet from the surface, having been two years in sinking.

IMPERIAL-EMPIRE.—The main drift east on the 1,850-foot level has penetrated the west wall of the ledge, and to-day is just entering a fine quartz formation, but has not penetrated this body far enough to yet determine anything in regard to its real value.

GLOBE CONSOLIDATED.—The main west drift is still pushed steadily ahead, the rock in the face gradually softening and showing evident indications of a near approach to the ore vein. Sinking the main incline is progressing as usual. The cross drift in the new ore body that is now being opened above the old tunnel level, shows the body of ore to be much more extensive than was at first anticipated.

GOULD & CURRY.—The main east drift, on 1,500-ft. level, is still slowly carried forward in a mixture of quartz and porphyry, the flow of water from the face gradually though slowly decreasing. The face of the main east drift, on the 1,700-ft. level, is in a mixture of clay, quartz and porphyry. This drift is not yet far enough east to cut the east ore vein, as developed on the levels above. Sinking the double winze, below the 1,700-ft. level, is making steady progress. Repairing the north compartment of the main shaft is completed. All the machinery is in good running order, and prospecting throughout the entire mine is being pushed with all the vigor possible.

OPHIR.—A very favorable and promising ore development has been made during the past two days in cross-cut No. 2 east, on the 1,300-ft. level. A drift has been started south from this cross-cut which is still in good ore. The bottom of the south winze being sunk in cross-cut No. 1, on this level, is also in good ore. The main south drift, on the 1,700-ft. level, is still being driven vigorously ahead to connect with the winze from the level above at the earliest possible moment.

CROWN POINT.—The north ore breasts on the 1,000-ft. level have shown a steady improvement during the past week and promise a fine yield of good ore. The ore breasts on the 1,200, 1,300 and 1,400-ft. levels are all looking well and yielding the usual amount of milling ore. Daily yield, 550 tons of ore. The east ore body on the 1,400-ft. level is opening out finely and of excellent quality.

DAYTON.—The mine is looking splendid throughout; the ore stopes on both the second and third station levels continue to yield the usual amount of good milling ore, keeping both Woodward's and Brigg's mills steadily running, crushing ore from the mine.

UTAH.—The main south drift, from the west tunnel, is still making good progress, running through barren quartz with spots of clay and porphyry mixed. Cross-cuts both east and west have been started from this drift to more thoroughly prospect and determine the value of the ore vein. The up-raise from the west drift on the 400-ft. level, has made connection with the old upper works, greatly benefitting the air circulation.

SILVER HILL.—The machinery is all working finely, and everything in and about the mine in excellent working condition. The flow of water from the south drift on the second station level is steadily decreasing, and work has again been resumed in the face of the drift. A raise has been commenced from the second station drift to tap the old St. Louis chimney, and some good developments from that quarter may be looked for soon.

CALERONIA.—Raising up on the third compartment and re-timbering the shaft between the third and fourth station levels is making steady progress.

SATAGE.—The face of the main west cross-cut on the 1,900-ft. level is still in hard quartz giving low assays. The west cross-cut from the main south drift on this level is still being driven energetically ahead, the face in hard blasting porphyry. This drift is not yet far enough to reach the ore vein. Sinking the main incline for opening the 2,000-ft. level is making rapid progress.

PHIL. SHERIDAN.—The new working shaft is fairly commenced and during the week good progress was made in sinking. It consists of three compartments, and will open and develop the ledge at a great depth. The grading for the

hoisting works is about approaching completion. **SECRETORIA ROCK ISLAND.**—The north drift from the main west tunnel is still driven vigorously ahead following the east wall of the ledge. Some very fine ore was found yesterday next to the east, or hanging wall. The ledge shows great improvement as the work progresses to the northward.

CALIFORNIA.—As soon as the 1,400-ft. station of the Virginia Consolidated shaft is finished, another drift north will be started to open and prospect that level.

McMEANS.—Driving the main west tunnel is making excellent progress, the rock in the face presenting a much softer, broken and jumbled up appearance than heretofore, with occasional streaks of quartz, some of which is five or six inches in thickness and gives low assays.

BECKER.—Daily yield, 550 tons of ore, from the 1,000, 1,200, 1,300 and 1,400-ft. levels. The main incline is down 185 feet below the 1,400-ft. level. The winze, starting from the same level, is down 100 feet. The 1,400-ft. station drift is in 200 feet, in good working ground. The mine is looking remarkably well in every part.

OVERMAN.—Sinking the winze, from the 1,000 ft. level, is making steady progress without change of interest to record. The south drift, from the 200-ft. station, in the winze, is still driven ahead, following the west wall of the ledge.

CHOLLAR-POTOSI.—Daily yield, 100 tons of ore, assaying \$31 per ton. The ore bodies on the upper levels show a little improvement in the quality of the ore extracted.

LEO.—Main tunnel still driving ahead into the hill, following the vein. The rich ore streak still holds out about the same width—20 inches—as last week, and is of the same quality. The ore is being carefully sacked up and taken care of.

WOODVILLE.—The main incline is down 40 ft. below the 300-ft. level in fair sinking ground.

KNICKERBOCKER.—Sinking the shaft is making steady progress. Repairing the main west drift at the 400-ft. level is completed a distance of 550 feet, and there is still 150 feet more necessary to complete the work.

LADY BRYAN.—New shaft down 110 feet and in good working ground. The main building over the shaft, blacksmith shop and other out-buildings, is about completed, and the hoisting machinery is being placed in position.

YELLOW JACKET.—The main incline is down fifty feet below the 1,640-ft. level, the sinking making steady progress.

BUCKEYE.—The streak of ore developed in the south drift at the 450-ft. station still continues, but of not quite so good a quality.

SUCCOR.—The new shaft is down 441 ft., the bottom in extremely hard blasting granite rock.

BALTIMORE CONSOLIDATED.—Sinking the shaft is making slow though steady headway.

NEW YORK CONSOLIDATED.—Repairing the shaft is completed, the new machinery in place, and draining the water from the shaft preparatory to resume sinking, is making rapid headway.

KOSKUTH.—The north drift from the main tunnel at the 200-ft. level has developed some fine ore during the past week.

JULIA.—Work progressing at all points as usual.

ROCK ISLAND.—The shaft is down 80 feet in good sinking ground, the sinking making excellent headway. Excavating pits for the new engine beds has been commenced.

UNION CONSOLIDATED.—The main drift north on the 1,300-ft. level, following the west wall of the ledge, is making fair progress and shows some excellent ore indications.

SOUTH COMSTOCK.—Incline down 28 feet below the 150-ft. level. Ground works well, and no water interferes. Sinking at present in a mixture of gypsum and quartz.

NEVADA.—The ore in the south drift still continues to widen and improve in quality, showing evident indications of the forming of another fine chimney.

ALHAMBRA.—The new hoisting works are about completed, the machinery in place and everything will be in readiness to start up in two or three days more.

EUROPA.—Sinking the winze in the north cross-cut from the main west tunnel is making steady headway, the bottom still in very favorable vein matter.

GENESSEE No. 2.—The sinking of the new shaft progresses at a very satisfactory rate, it being down to the depth of 82 ft. to-day. Rock looking finely.

LADY WASHINGTON.—The erection of the new pumping machinery is rapidly approaching completion.

SOUTH STAR.—New shaft down nearly 100 ft. The ore improves in quality, giving better assays. Will erect hoisting works shortly.

TYLER.—The shaft is down 82 ft. below the 200-ft. level in good sinking ground.

MINT.—The new machinery is all working finely, and the water being drained from the shaft preparatory to resume sinking.

SENATOR.—The new reels are in place and everything in readiness to resume sinking the shaft.

PICTOR.—Main tunnel driving ahead, with porphyry and stringers of quartz in the face.

A BLAST of seven hundred kegs of powder was put off in the Golden Gate claim, at Forest Hill, one day this week, doing good execution. The discharge was made by electricity.

CITIZENS of San José have discovered good indications of quicksilver in the southern portions of Santa Clara valley.

The Weaverville Ditch and Mine.

The *Trinity Journal* says: Last Saturday we took a little walk up Oregon Gulch mountain, in company with Mr. Simpson, of Cerro Gordo, Inyo county, J. E. Spencer, of Lodi, San Joaquin, and Capt. Geo. H. Atkins and P. Paulsen, of Weaverville. Arriving at the seat of operations, we found that the Weaverville Ditch and Hydraulic Mining Company had not been idle, but that half a mile of the prettiest ditch we ever saw was completed and another half mile was nearly graded. The ditch is four feet wide on the bottom, six and one-half feet on top, three feet deep, and runs on a grade of 11.20 feet to the mile. It will carry 2,500 inches of water this season, and after becoming settled will carry 3,000 inches or more. The line is graded seven and one-half feet wide and the excavation made close into the bank, leaving not less than a foot of solid earth on the outside, which greatly strengthens the ditch and will do much to prevent breaks and other damage. Thus far the ground has been of a character easily worked, much of it such that it could be spaded. Most of the rock is of a rotten, seamy character, easily worked, and but little blasting has therefore to be done. Mr. Loveridge, the company's engineer, tells us that the ground already worked is a fair example of that which is to come, as near as he can judge. No fluming will be required on the line, which, when completed, will be nearly four miles in length, and all ditch. We were somewhat surprised to find oyster shells along the line and, supposing them to be indigenous to the soil, made inquiry and were informed that Jimmy Landis and the other boys didn't go to camp at noon but lunched on the ditch.

Returning about noon to the company's camp at the Mountain House, our party did ample justice—and more, too—to a square meal which was set before them, and which was fully appreciated. Feeling greatly refreshed, we again started out, this time in company with Mr. D. W. George, superintendent of the work, to visit the mining property belonging to the company.

Near the top of the divide they are engaged in running a cut; from this they will tunnel a short distance, raise a shaft, and sluice out a hole for a reservoir. The site is an excellent one, and the extent to which a reservoir may be made is very great. From this reservoir it is intended to run the water down a ravine and take it up in a pipe a short distance above the claim now being worked by Jas. Ward, this being the place where the company intend doing their first mining. Eleven hundred feet of 15-inch iron pipe will be required to convey the water on the claim, and 250 feet pressure will be needed. Much more pressure can be secured if needed, but the bank being easy to cut, 250 feet is considered all sufficient. A four-foot flume, of forty boxes, will be put in here, and the dirt dumped and redumped, and run through three six-foot flumes, of four boxes each, before it reaches the head of gulch several hundred feet below. Under-currents and all other improvements and appliances for saving gold will be used extensively. So much for the proposed manner of working.

The gravel deposit forming the Oregon Gulch mountain, we are free to assert, is not equalled by anything of the kind in the State. The reservoir cut, on the top of the hill, is in gravel of similar character and prospects equally as well as that being worked by Mr. Ward some nine hundred feet below the summit. The slate bed-rock is more than a hundred feet lower than the level on which Ward is working and gravel is of the same character and quality. If this bed-rock goes on a level, as it undoubtedly does, we have here a gravel deposit of not less than one thousand feet in depth, of unknown bounds—but very extensive—and which prospects very rich wherever it has been tried. As to the prospects, from six to ten cents is frequently found in a shovelful of the gravel, and it is a rare occurrence to wash a shovelful without obtaining several colors. The hole, from which Mr. Ward has taken some ten thousand dollars, is not so large but that it could be worked in ten days with a Little Giant and a good head of water. On the bed-rock below, Mr. Dyer has this winter been running a claim—using Ward's water—has already taken \$600 from his flume, and will probably get as much more in cleaning the bed-rock. The piece of ground he has sluiced off is about equal to half-a-day's work with a good rig and plenty of water. It may seem like exaggeration when we say that the amount of ground these men have moved was so small and paid so largely, but such are the facts, known to all who are conversant with the matter. And they did not get a very large proportion of the gold at that. Desiring to know how much fine gold he lost, Mr. Ward last summer washed sixty buckets of his tailings, in a rocker, and realized five dollars. Eight cents to the bucket, in tailings, is pretty good itself. This shows that the gold is certainly there, and Mr. George says he is going after it, and has no fears as to the result. We have never heard him speculate upon the probable amount of pay, but with a good rigging and plenty of water it cannot fall much below five hundred dollars per day, and is liable to go to a thousand or even higher.

It is probable that after this season the company will find it necessary to work this immense deposit in three or four benches, as it

will be an utter impossibility to work a 1,000 ft. gravel bank from the bed-rock. As to how this immense bed or channel of aeriferous gravel was deposited there, much speculation is indulged in, but it certainly seems that in ages long ago Oregon Gulch was the natural outlet of Weaver Basin. On this head we had intended to say something in this article, but having already made it longer than we intended, shall have to drop the subject here and continue it at another time.

State Mineral Lands.

We give below the full text of McKusick's bill for regulating the sale of State mineral lands:

An Act regulating the sale of Mineral Lands belonging to the State. Approved March 28, 1874.

SECTION 1. Any person desiring to purchase from this State any portion of any sixteenth or thirty-sixth section that shall have been designated by United States survey as of a mineral character, or which is so in fact, shall make an affidavit before some officer authorized to administer oaths, that he or she is a citizen of the United States, or, if a foreigner, that he has filed his intention to become a citizen of the United States, that he or she is of lawful age, and desires to purchase said land, giving descriptions thereof by legal subdivisions; that he or she has not entered any portion of such mineral lands, which, together with that applied for in such affidavit, will exceed forty acres; that there is no occupation of said land adverse to that which he or she holds, or, if there be any adverse occupation thereof, then he or she must state the name of such adverse occupant, together with the fact that the plat of the township has been on file six months or over, and that such adverse occupant has been in occupation six months or over.

SEC. 2. Any person that shall be in actual possession of any of the said lands described in section one, at the time of the survey thereof by the United States, "or at the time of the passage of this Act," shall be considered a preferred purchaser thereof; provided, he or she make his or her application for the purchase of the same within six months after the filing of the plat of such survey in the United States Land-office, or within ten months after the passage of this Act.

SEC. 3. When a contest shall arise as to the mineral character of the lands applied for, or from any other cause, and either party shall demand a trial in the Courts of the State, the Surveyor-general, or the Register before whom the contest is made, must, within thirty days after the adverse application is filed, unless sooner referred at the request of either claimant, make an order referring such contest to the District Court of the county within which the land is situated, and must enter such order in the proper book of his office, and forward a copy thereof to the clerk of the Court to which the reference is made. Upon the filing of a copy of such order with the clerk of the Court, either party may commence an action in said Court to determine the conflict, and the Court shall have full and complete jurisdiction to hear and determine the same. Unless an action shall be commenced within ninety days after the copy of the order of reference shall have been filed with the clerk of the Court, the party making such demand, or the adverse claimant, if the case is referred without demand, shall be deemed to have waived and surrendered his or her right to purchase, and the Surveyor-general or Register shall proceed as though his or her application had not been made.

SEC. 4. All lands sold under the provision of this Act shall be sold for the sum of two dollars and fifty cents per acre, in United States gold coin, payable to the Treasurer of the county in which the lands are situated, within fifty days from the date of the approval by the Surveyor-general; and in case said payment is not made within said fifty days, the land described in the location shall revert to the State without quit, and said location shall be and become null and void. All payments made to the County Treasurer, as above provided, shall be paid over and accounted for as other moneys received for State lands are required to be paid over and accounted for.

SEC. 5. The Surveyor-general and Register shall, in the matter of approving locations, issuing certificates of purchase or patents, or in other proceedings relating to the sale of lands of a mineral character, which proceedings are not provided for in this Act, proceed in the same manner as is now provided for the sale of sixteenth and thirty-sixth sections which are not of a mineral character.

SEC. 6. All patents issued by the State to any portion of any sixteenth or thirty-sixth sections shall be subject to any vested and accrued water-rights, ditches and reservoirs used in connection therewith, acquired by priority of possession under local customs and the decisions of the Courts, and the right of way for the construction of ditches and canals for mining and other purposes over all of the sixteenth and thirty-sixth sections owned by the State is hereby granted and confirmed.

SEC. 7. After the passage of this Act no patent shall be issued by the State for any of the lands described in this Act upon which, at the time of application therefor, there was and still is any actual *bona fide* mining claim, except to the person who is the owner of such mining claim under local mining customs, and not to such owner in excess of forty acres. And when an applicant for such lands, not owning such mining claim, shall have paid the purchase-

money therefor, in whole or in part, he may present his certificate of purchase, and receive in exchange therefor from the Register a certificate showing the whole amount paid, and the Controller, upon the surrender of such certificate, must draw his warrant in favor of the person surrendering such certificate, for the amount therein specified, on the Treasurer of the State, who must pay the same out of the fund into which the purchase-money was paid; provided that the owner of such mining claim under such mining customs shall apply to purchase the same within six months after the plat of the township containing such land shall have been filed in the local United States Land Office, or within ten months after the passage of this Act; and provided further, that any owner of a *bona fide* mining claim who shall have entered into an agreement with the applicant for any portion of the sixteenth or thirty-sixth sections, upon which said mining claim is situated, for the procurement of a title for the same, shall not avail himself of the provisions of this section. The Governor of the State shall not sign any patent contrary to the provisions of this Act.

SEC. 8. All Acts or parts of Acts in conflict with this Act are hereby repealed.

SEC. 9. This act shall take effect and be in force from and after its passage.

Free Gold Coinage at the Mints.

The Lower House of Congress has just passed an amendment to the coinage Acts of February 12, 1873, which make the coinage of gold free at all the mints. The amendment reads as follows:

That no charge shall hereafter be made for the coinage of gold, and the charge for converting silver into gold dollars, for melting, for refining when bullion is below standard, for lengthening when metals are contained in the bullion which render it unfit for coinage, for separating the gold or silver when those metals exist together in the bullion, and for the preparation of bars, shall be fixed from time to time by the Director of the Mint, with the concurrence of the Secretary of the Treasury, so as to equal, but not exceed, in their judgment, the average cost at each mint and assay office of the material, labor, wastage and use of machinery employed in each of the cases aforementioned.

The English system is practically adopted by this amendment. It was estimated that the Government receives for gold coinage, under the old law, from sixty thousand to eighty thousand dollars a year. But this sum it collects chiefly from miners, and gold produces this sum.

The spirit of the debate on the amendment is well illustrated in the following:

Mr. Randall—Then we are to understand that the Mints are in future to coin the bullion without cost to those who make the deposit of the bullion?

Mr. Hooper—Without any charge for coinage; the depositors will still have to pay other expenses.

Mr. Randall—I am not asking these questions in any spirit of opposition to the bill, for I have long believed the policy of the Government should be to do what is provided for by this bill. It proposes what, I believe, is the English system.

Mr. Hooper—This is the English system, and that of most if not all the continental countries.

Mr. Hale, of Maine—How much does the Government now receive at its different mints from this source, and which will be cut off if this bill passes?

Mr. Hooper—From sixty to eighty thousand dollars a year.

Mr. Hale, of Maine—So that will make a difference against the Government of from sixty to eighty thousand dollars a year?

Mr. Hooper—Yes sir, and a gain to the miner and a gain to the public and a gain in point of principle, because it makes the inducement stronger to coin gold in this country instead of sending it abroad to be coined.

Mr. Hale, of Maine—But undoubtedly next year, in keeping up the Mint establishments, we shall be obliged to appropriate from sixty to eighty thousand dollars more for this branch of the public service than we do at present.

Mr. Hooper—I should doubt if it would have precisely that effect, because the business of the Mint will be increased, and the charges on the other operations, such as assaying, purifying, etc., I think would nearly make up the loss.

Mr. Hale, of Maine—That must be something problematical.

Mr. Randall—That its effect will be to keep gold in the country is, however, almost a certain proposition.

Mr. Holman—Is the effect of this amendment that the coinage of gold is to be relieved of the charge of one-fifth of one per cent.?

Mr. Hooper—That is all.

VALUES.—One ton (2,000 pounds avoirdupois) of gold or silver contains 29,163 Troy ounces, and, therefore, the value of a ton of pure gold is \$602,799.21, and of a ton of silver, \$37,704.84. A cubic foot of pure gold weighs 1,218.75 pounds avoirdupois; a cubic foot of pure silver weighs 656.25 pounds avoirdupois. One million dollars gold coin weighs 3,658.8 pounds avoirdupois; one million dollars silver coin weighs 58,925.9 pounds avoirdupois. If there is one per cent. of gold or silver in one ton of ore, it contains 291.63 ounces Troy, of either of these metals. The average fineness of the Colorado gold is 781 in 1,000 and the natural alloy: gold 781, silver 209, copper 10; total 1,000. The calculations at the mint are made on the basis that 43 ounces of standard gold, or 900 fine (coin) are worth \$800, and 11 ounces of silver 900 fine (coin) are worth \$12.80.

The Mineral Hill Mines.

The London correspondent of the *N.Y. World*, writing under date of Mar. 26th, says: A case tried yesterday in the Vice-Chancellor's Court throws a fine light upon the manner in which certain things are done in London. In the latter part of 1871 an American gentleman, Mr. Ashbury Harpending, came to England for the purpose of selling certain mines in Nevada. He called these treasures "the Mineral Hill Mines," and he represented that they were so rich that more than £200,000 worth of silver ore lay on the top of the ground.

A Mr. F. Doulton introduced Mr. Harpending to Mr. Albert Grant—he who now is Berou Grant, M.P. for Kidderminster, and Lord of Leicester Square. Mr. Grant agreed to do the business, and he formed a company called the California Mining Company, with a nominal capital of £1,000,000. But the only shareholders and directors in this company were seven clerks in the employment of Mr. Grant. One was the President, another the Secretary, a third the Treasurer, and the other four were directors. This great company was duly registered, and on the 14th of May, 1871, an agreement was entered into between it and Mr. Harpending for the purchase of the Mineral Hill mines for the sum of £230,000, which was very cheap considering that silver to the value of £200,000 was on the top of the ground, and probably millions more below it. This sale was dated back to the 20th of February.

Mr. Grant then formed another company, called the Mineral Hill Silver Mining Company, for the purchase and working of the property which the California Mining Company had thus acquired. On the 21st of June the property, which had been purchased on the 14th of May for £230,000, was sold to this second company for £480,000—one-half in cash and one-half in fully paid-up shares. Mining engineers had been sent out, who reported that the mines were rich; but they soon turned out to be worthless, and the company is now being wound up. But Mr. Doulton had been promised by Mr. Grant a reward for introducing Mr. Harpending to him, and Mr. Doulton in his turn had promised to give to a Mr. Thomas Smith one-half of what he got from Mr. Grant over £4,000. Mr. Grant paid Doulton £5,000, then £3,000, and then gave him 1,000 shares in Mineral Hill; but meanwhile Doulton and Smith had quarrelled, and Smith served Grant with a notice that one-half of these last payments belonged to him. The notice was served before the money was paid, but Grant disregarded it. Doulton now died, and Smith sued Grant for the money.

The Vice-Chancellor ruled that the claim was a good one, and that Grant must pay the money over again—£1,750, with interest at four per cent. The point which is worthy of your attention is the peculiar manner in which such financing as this is done. To buy a worthless piece of property for £230,000, and to sell it again for £480,000 within five weeks, is not a bad thing, except for the buyers.

MCWAYNE'S ONE-TRACE RAILROAD.—Chandler McWayne patented, October 22d, 1861, a device for an elevated railway, which is now attracting attention in Colfax, California. His model track is several hundred feet in length, resting upon upright standards. The car is balanced over the track "saddle-fashion," partly above and partly lower than the track. Side friction wheels are employed to steady its motion, and grip-pulleys will assist the locomotive to ascend steep grades. We can not, without further demonstration, recommend his device, but wish that it may be worked up to a successful California invention, and therefore call attention to it.

INCLINE MACHINERY.—The Crown Point Mining Company are laying the foundations for some powerful machinery to be used in hauling ore up the incline. The engine will have a 20-inch cylinder, 3½-foot stroke. The capacity of the ore-car used on the incline will be 10 tons.—News.

THREE tons of copper matte were shipped this week from the newly located mine near Spencerville, Nevada county. The lead, according to the Grass Valley Union, is 74 feet wide, and contains about eight per cent of copper.

TRUCKEE is busy supplying charcoal to the smelting works in Utah, as the Government has forbidden the cutting of wood and manufacture of charcoal on the public lands of Utah.

THE Hoosac Smelting Works, says the *Eureka Cupel*, are being overhauled and repaired, preparatory to a speedy beginning of the business of extracting plumbiferous silver from argentiferous ore.

THE New York mill in Plumas county is about to be removed to the mouth of the Dixie cañon, to crush rock from the Green mountain ledge.

A COMPANY has been formed to prospect a coal vein, near Wheatland. A shaft has been sunk 50 feet.

ALL the mills in Gold Cañon and Silver City are running up to their full capacity.

SILVER CITY mining operations are being prosecuted vigorously.

USEFUL INFORMATION.

Sugar and Salt, Pickles and Peppers.

The following is from a paper furnished by Dr. Wetherbee to the *Hearth and Home*:

Sugar and its kindred substances, molasses, honey, etc., are very liable to abuse; still they are very useful as a portion of our daily food, on account of the carbon which they contain, and which has been termed "the food of respiration." On this account aged persons and those who habitually suffer from a feeling of cold, by reason of a low temperature of the blood, require much more of the saccharine principle than the young or middle aged. It is also considered a good remedy for those who are afflicted with lung and throat complaints. Those who are daily employed in various branches of sugar refining, the manufacture of confectionery and its kindred branches, are seldom attacked with consumption, and are generally remarkable for the plump, smooth appearance of the flesh and skin.

Sugar when in solution, and exposed to the oxidizing influence of the atmosphere or otherwise, first passes into the vinous fermentation, by which alcohol is generated; and afterward by further oxidation, or by the acetone fermentation, produces vinegar, or acetic acid, the qualities of which will hereafter be discussed. The sources of sugar are very numerous, but the greater proportion in use is derived from the sugar cane, the beet-root and the ssp of the sugar-maple. Molasses is the liquid uncrystallizable portion which is drained from the sugar, and on account of its various impurities, is sometimes apt to cause bowel complaints, if used in too great quantities. Besides these sources, sugar may be obtained by a chemical process, from linen rags, paper, etc., but of course this method is too expensive to be employed except as scientific experiments.

Salt preserves animal and vegetable substances from decay through its strong attraction for water, depriving them of their greater portion, so that a sufficient quantity does not remain to induce putrefaction. Its use to the animal economy is to furnish hydrochloric acid, an ingredient in the gastric juice; also soda to the bile. But it is doubtless used among us in by far too great excess, for while its proper use is to preserve from decay, its action when taken in excess in the system is to impair digestion, and to produce an excess of its elements, resulting in the disease known as scurvy.

The inhabitants of some of the South Sea Islands employ no salt in their food, and salted fish is to them even more disgusting and sickening than its entire absence in animal food is to us, thus proving that the habit of using it is only an acquired one. Even among us, we find persons who can never use it in any perceptible quantity without symptoms of violent fever, which sometimes lasts for several hours.

Vinegar, or, as it is termed in chemical parlance, diluted acetic acid, is one of the most efficacious antidotes against the injurious results of the excessive use of salt. Its direct action is to convert the substance of the salt into the acetate of soda, thus producing a gentle alterative effect upon the bowels, and a cooling, anti-febrile effect upon the blood. When too strong, or when taken in too great quantities, it may produce an acid reaction in the system, or corrode the coats of the stomach, and therefore should be used, like all other condiments, in moderation.

Its usual adulteration is with sulphuric acid, a substance which, though it is occasionally useful as a medicine, should not be employed as a general article of diet. Acids of all kinds affect the digestive organs in various ways, though they do not directly contribute to the nourishment of the system.

Pickles may to a certain extent be nourishing, since the vegetables of which they are composed frequently possess more or less nutriment, but they should be used sparingly. The most dangerous adulteration of pickles, especially when it is desirable to have them of a bright green color, is verdigris, or other salts of copper, all of which are highly poisonous. Even when the vinegar is boiled in a copper or brass vessel, it acts upon the metal, producing an acetate of copper, or verdigris. Glazed earthen-ware is also improper for holding vinegar, as the glazing is a compound of lead, which is soluble in vegetable acids, in which state it gives rise to colics and other dangerous symptoms.

As an anti-scurbutic, or preventative and cure for scurvy, pickles should form a part of all army and marine stores; and in mining districts where salted provisions constitute the greater part of the animal food in use, their value is so much appreciated that almost fabulous prices have been paid for a single gherkin, or for a pickled onion not bigger than a walnut. During the past few years the tomato has become a popular fruit for pickling, and is, no doubt, quite as wholesome as any other.

Spices mostly act as stimulants to the coats of the stomach, on account of the essential oil which they contain, and they form an important class in the list of useful medicines. Used in excess, they are apt to heat the blood.

Allepice, in small quantities, is a very powerful adjunct to medicines for the cure of dyspepsia, etc., and the essential oil, as well as that of clove, etc., is often used to allay toothache.

Ginger is also used as a stimulant in food,

and as a remedy against colds, colics and vomiting, and has been found to be an excellent antidote against sea-sickness.

Black pepper is sometimes employed with good success as a cure for nausea, dyspepsia, certain forms of gonorrhea, or as a stimulant in paralysis. In India it is much used as a remedy for vomiting, in cholera morbus, and in some localities, when mixed with spirit and water, it is a popular preventive against the return of a paroxysm of intermittent fever. In this country it has often been known to relieve a sudden attack of bilious colic, when taken in doses of half a teaspoonful or more in a glass of hot brandy and water.

Many of the most expensive spices are adulterated to an enormous extent. A single firm of druggists in the city of New York recently sold in one year many thousands dollars' worth of black pepper, from which the oil, and the peculiar principle called piperin had previously been extracted; and the refuse portions of other spices yielding essential oils are dried, ground, and mixed with the genuine articles, for which they are invariably sold to the unsuspecting public.

Cobalt.

In its review of metals at the Vienna Exposition, *Engineering* has the following concerning cobalt: We have next to say a few words on the representation of cobalt, to which metal we have frequently alluded in our previous notes. Nickel and cobalt are in fact always so closely associated, that it will hardly be possible to find an ore of the one which does not at least contain at least traces of the other. The cobalt works, which produce oxide of cobalt and blue silicate of cobalt or "smalt," have had much to suffer from the manufacture of ultramarine blue, or artificial lapis lazuli; of late, however, they seem to have recovered, and their oxides find a profitable market as a fine blue color for china and Wedgwood wares.

In the German section at Vienna we found samples of oxide of cobalt shown by Fleitmann and Witte, of Iserlohn, the Victoria Nickel Works of Naumburg, in Silesia, and the Saxon Cobalt Company, of Schneeberg, which we have previously mentioned, and whose annual production of smalt and oxide is about 800,000 lbs., worth about £150,000. Austria annually produces preparations of cobalt, containing about 2,500 lbs. of metal, at her nickel works in Salzburg and Styria, and Hungary, preparations containing about 50,000 lbs. of cobalt at Dobosban, while the Kolba Metallic Mine Company, at Libthen, is also a producer of about 36,000 lbs. per annum of that metal. Cobalt ore was also exhibited from Dobsina, by Martin Sonntag.

The Swedish cobalt mines of Vena, in Nerike, and of Tunaberg, seem to be at a standstill, while the cobalt works of Skutumpah and Modum, in Norway, which are the property of the Saxon Cobalt Company, have been started again with success. The ore is there cobalt-glance and arsenical cobalt pyrites, and is found more or less intimately mixed in a metalliferous band or zone of mica-schist, varying from a few to over 100 fathoms in thickness, and dipping almost vertically. The ore is stamped and washed, carefully calcined in order to drive out its sulphur and arsenic, and then either melted for blue smalt glass, or refined for black oxide. We have finally to notice again Josef Wharton, of Philadelphia, for his excellent exhibits of oxide, sulphate and metallic cobalt, the latter being smelted in a furnace of particular construction, probably on the Deville system.

FUEL.—With equal weights, that which contains most hydrogen ought, in its combustion, to produce the greatest volume of flame where each kind is exposed under like advantageous circumstances. Thus, pine wood is preferable to hard wood, and bituminous to anthracite coal. When wood is employed as a fuel, it should be as dry as practicable. To produce the greatest quantity of heat, it should be dried by the direct application of heat; as usually employed, it has about twenty-five per cent. of water mechanically combined with it, the heat necessary for the evaporation of which is lost. Different fuels require different volumes of oxygen; for the different kinds of coal it varies from 1.87 to three pounds for each pound of coal. Sixty cubic feet of air are necessary to furnish one pound of oxygen; and, making a due allowance for loss, nearly 90 cubic feet of air are required in the furnace of a boiler for each pound of oxygen applied to the combustion.—*Coal Trade Journal*.

COMPOSITION FOR CASKS.—The object of a newly-patented process is to render casks and other vessels air-tight and water-tight, and prevent their becoming mouldy, sour or stinking, and thus better suited for keeping their contents in a sound condition. The improved composition consists of gum eucalypti or colophony, either alone or mixed with gum eucalypti, or other resin capable of being dissolved in spirits, to which is added for the purpose of giving body and hardness either carbon, calcined ochre, or burnt clay, or a mixture of these in a pulverised state. The composition is applied to the heated cask or vessel with a brush, after which the spirit is blazed off and the cask or vessel again heated, until the preparation has thoroughly penetrated the fibers of the wood; or the composition may be applied in a heated state.

GOOD HEALTH.

A Neglected Source of Food.

Agos ago when our fore-fathers were worshippers of Odin and the rest of the dead divinities of Northern Europe, horse flesh was accounted a delicacy fit for the gods. When a warrior died, the "funeral baked meats" were carved from his slain charger; and in all religious celebrations the horse figured, as the bullock did in the sacrificial feasts of other nations. The horse flesh and paganism were found to be inseparable when the Germanic and Scandinavian tribes were christianized by royal proselitation. The new made christian could not begin a dinner at which his favorite meat appeared without relapsing to his ancestral religion and going through the entire round of pagan rites with which horse flesh had been so long associated. As a natural consequence horse flesh became not only synonymous with paganism, but one of its defenses, we should have said bulwarks if the sound had permitted. Against it the bulls of the church were hurled, and its use was prohibited under pain of eternal damnation. Gradually, as christianity gained ascendancy, the obnoxious meat passed out of use, and in process of time it became to be regarded by Europeans as "long pig" was by the christianized descendants of man-eating Fiji islanders, with an abhorrence as intense as the original liking had been.

Subsequent generations have inherited the prejudice and forgot its origin. To-day the multitude stand ready "to cry unclean" the moment horse flesh is mentioned as an article of food, though it would puzzle them to give one substantial reason for so regarding it.

The truth is that no meat can be cleaner. The horse is one of the nicest of feeders, and as choice in his drinking as in his diet; and, as has been abundantly proved by the experience of modern Europe, where horse flesh has lately become an important element in the food, supply, the meat which we reject is at once wholesome, nutritious, and nearly, if not quite, as savory as beef. As we are no longer in danger of relapsing into paganism with the taste of it, the only sanitary reason, moral or otherwise, for avoiding it is done away with.

There remains the economical reason for its disuse arising from the fact that good horses are worth more for other purposes. But the time comes when the best of horses cease to be profitable for service. What then?

Occasionally a favorite animal is provided for in his old age, and allowed to end his days in all the comfort that nature will permit. The majority, however, are turned over to the tender mercies of the cruel to be used up, more or less speedily, in rough and ill requited labor. To guard their favorites from this unhappy end, it is becoming a common practice among considerate people to shoot their horses when no longer fit for the carriage, though they may still be far from worn out. Of the nine million horses in the United States, a million might fitly be disposed of in that way every year, to make room for younger and more serviceable animals. In other words, our food supply might be augmented by something like a thousand million pounds of good meat annually. We throw it away—for a prejudice.

That this prejudice will be overcome in time, we have not the slightest doubt. The tendency of our civilization is to multiply food consumers while lessening the relative number of producers. As a natural consequence we must be more and more careful to avoid unnecessary waste. Every available source of wholesome food must be husbanded, and this among them. Unfortunately those who would be most directly benefitted by the addition of horseflesh to our lists of meats are just those whose prejudice against it is most intense. Here, as in Europe, it must first gain a place on the tables of the well-to-do.

Perhaps as simple a plan as any for effecting this would be the following: We have noticed the growing custom of shooting horses when their term of profitable service has come to an end by age or accident. Instead of burying the carcasses or giving them to the renderer to be converted into soap grease and fertilizers, the flesh might be properly dressed and distributed among those who, from curiosity or conviction of its wholesomeness, might desire to give it a trial. If pains were taken to announce this intention before hand, and to prove to intending eaters that the horses were in good condition and free from disease, there would be little difficulty, we imagine, in disposing of the choicest cuts. All that is required is a beginning, and this course would ensure it with the least amount of trouble and cost.—*Scientific American*.

HOW THE EYE IS SWEEPED AND WASHED.—For us to be able to see objects clearly and distinctly, it is necessary that the eye should be kept clean. For this purpose it is furnished with a little gland, from which flows a watery fluid (tears) which is spread over the eye by the lid, and it is afterwards swept off by it, and run through a hole in the bone to the under surface of the nose, where the warm air passing over it while breathing, evaporates it. It is remarkable that no such gland can be found in the eyes of fish, as the element in which they live answers the same purpose.

If the eye had not been furnished with a liq-

nid to wash it, and a lid to sweep it off, things would appear as they do when you look through a dusty glass. Along the edges of the eyelids there are a great number of little tubes or glands, from which flows an oily substance which spreads over the surface of the skin, and thus prevents the edges from being sore or irritated, and it also helps to keep tears within the lid. There are also six little muscles attached to the eye which enable us to move it in every direction; and when we consider the different motions they are capable of giving to the eye, we cannot but admire the goodness of Him who formed them, and thus saved us the trouble of turning our heads every time we wish to view an object.—*Ez.*

Torturing the Human Foot.

Science, in its comprehensive range of subjects, has at last condescended to direct attention to promoting the comfort of the human foot—to pointing out the deformities of the shoe we wear. Mechanical ingenuity has exhausted itself in the construction of machines which turn out shoes automatically, their whole object being rapidity of production after rigid models, to which the foot is compelled by painful experience to conform itself, corns and bunions to the contrary notwithstanding. Civilized communities wear the worst-fitting shoes and suffer the most from them. The Indian undergoes no suffering from his loosely made moccasins, nor does the Oriental cultivate corns in his sandals. But the hard, rigid, tight-fitting shoe of the European and American has, from time immemorial, held its place as an instrument of torture. Yet, when compared with the shoes in use a century ago, those of modern manufacture when made by hand do give evidence of some amelioration, though the best of them are still deficient in what the comfort of the foot requires. Dr. Hermann Mopor, a Swiss philosopher of the humanitarian school, has taken the subject in hand, and presents some considerations deserving attention from intelligent men at the head of great American shoe factories. He denounces the workman who produces a shoe that will pinch, and demands the production of one which will afford to a foot distorted by the pinching it has already undergone, a fair chance of returning to its proper shape, and the full possession of its power for carrying the body forward. He places great emphasis on the proper accommodation of the great toe, alleging that it is of prime importance to keep it free from all constriction or distortion. Upon this toe, in walking, the weight of the whole body turns at every step in a natural foot; therefore, in such a foot it is in a straight line with the heel. The doctor ascertains that a central straight line drawn from the point of the great toe to the middle of its root, if continued, would pass very exactly to the middle of the heel. But our modern misfitting shoes destroy this natural anatomical arrangement, so distorting it as to force the point of the toe inward and the root outward. No shoe, for a foot already injured by wearing such as are ill-fitting or constrictive, should ever be made of the exact size of the injured foot.—*Ez.*

What the Microscope Reveals—With a Moral.

Lewenbeck tells us of insects soon with the microscope, of which 27,000,000 would only equal a mite.

Insects of various kinds may be seen in the cavities of grains of sand.

Mold is a forest of beautiful trees, with branches, leaves and fruit.

Butterflies are fully feathered.

Hairs are hollow tubes.

The surface of our bodies is covered with scales like a fish; a grain of sand would cover one hundred and fifty of these scales, and yet a scale covers five hundred pores. Through their narrow openings the sweat forces itself like water through a sieve.

The mites make five hundred steps a second.

Each drop of stagnant water contains a world of animated beings, swimming with as much liberty as whales in the sea.

MORAL.

Have care as to the air you breathe, the food you eat, and water you drink.—*Hearth and Home*.

INTERMITTING LAMENESS.—The *Doctor* remarks: "A very curious thing has been described by Dr. Sabourin, namely, that lameness may ensue from obliteration of arteries. Horse lameness is often so obscure that any light proves desirable. It is not, however, confined to the horse, but extends also to man. The cause, as observed, is owing to obliteration of the aorta and iliac arteries. Commonly, in previous good health, the subject begins to limp, in one or two limbs to tremble, and finally to fall. Rest is commonly productive of relief. MM. Bouley and Goubaux long ago pointed out the nature of the affection in horses, while M. Charcot first pointed out its occurrence, comparatively rare, in man. Arteritis has been supposed to be the occasion in horses, owing to the violent efforts they have to make, and embolism in men. In any case, the occurrence affords a favorable illustration of the advantages of the study of comparative pathology."

TABLE OF CONTENTS.

GENERAL EDITORIALS.—A New Threshing
Engine; Copper, 273. Vein Systems of the Sierra
Nevada—Formation and Strike; Economy in the Use
of Quicksilver, 280. The Mining Committee in Con-
gress; Patents and Inventions, 284.

ILLUSTRATIONS.—The New Style "Headley"
Variable Cut-Off 15 Horse-Power Portable Engine,
273. Map Showing 200 Gold Mines in the Jurassic,
Etc., States of California, 281.

CORRESPONDENCE.—Cremation and Intermment
in Regard to the Cycle-Metamorphosis of Organic
Bodies, 274.

MECHANICAL PROGRESS.—A Gravity Eleva-
tor Railway; Improved Wheel for Vehicles; Ameri-
can Locomotives; Weight in Machinery; Safety Raft;
Improved Machine for Assembling Potatoes; Coloring
Plaster, 275.

SCIENTIFIC PROGRESS.—Reclaiming the
Desert Places; Underground Temperature; Treating
Sulphur Ores; A New Alkaloid from Morphine, 275.

MINING STOCK MARKET.—Tables of Daily
Sales and Prices and Comparative Prices for the Week;
Notice of Assessments; Meetings and Dividends;
Review of Stock Market for the Week, 276.

MINING SUMMARY from various counties in
California and Nevada, 276-7.

USEFUL INFORMATION.—Sugar and Salt,
Pickles and Peppers; Coal; Fuel; Composition for
Ores, 279.

GOOD HEALTH.—A Neglected Source of Food;
How the Eye is Swept and Washed; Torturing the
Human Foot; What the Microscope Reveals—With
a Moral; Intermittent Lameness, 279.

MISCELLANEOUS.—Buckeye Mountain;
Georgia Gold Fields, 274. The Weaver's Ditch
and Mine; State Mineral Lands; Free Gold Coinage
at the Mints; Values; The Mineral Hill Mines; Mc-
Wayne's One-Track Railroad; Incline Machinery,
278. Quicksilver at Vienna; Lancha Plana Coal
Mines; Raymond & Ely; Mexican Mines; Borax in
California; Co-operative Ship-Building to be Tested;
Eureka Mine; Gold Hill and Virginia City; The
Gulana Mining Bubbles; Coke; Rich Gravel Diggings
Discovered, 282.

BURNED OUT OF CHURCH AND HOME.—At the
recent fire in Colfax, Rev. J. J. Cleveland, a
Methodist clergyman, lost his valuable library
and household furniture, saving but one trunk
full of articles which he was alone able to drag
through the fiery street to a place of safety.
The Union church, at which he preached, the
only Protestant place of worship in town, was
destroyed. Mrs. Cleveland, an invalid, who
had for days been confined to her couch, was
hardly able to reach shelter by her own exertions.
Mr. Cleveland has labored faithfully
and humbly for over 13 years, exclusively in
the cause of christianity on this Coast. In an
hour made penniless among friends of similar
misfortune, they should be kindly remembered
by their friends and brethren elsewhere who
know them worthily.

REDUCING DUTY ON STEEL.—The Ways and
Means Committee are considering the reduction
of the steel duty. This is on an application by
manufacturers, representing one hundred mil-
lions of capital and 50,000 workmen, who say
American steel is nureliable in burnished and
edged tools. As they are compelled to use the
foreign article, they urge that the duty is unne-
cessary to protect American steel, and only
compels manufacturers to pay a higher price
for the foreign. They ask a reduction of
duties and a specific assessment. The Penn-
sylvania steel producers oppose this, and ask
10 per cent. increase.

THE SUTRO TUNNEL can now be worked on
three faces at once, shaft No. 2 having reached
the tunnel level. The header of the main tun-
nel is enlarged from 8x8 to 8x12 feet in size, to
accommodate the Burleigh drills they have
adopted.

A NEW 20-stamp mill is to be erected at the
mouth of the old tunnel of the Globe Consoli-
dated Company's mine. This will be so situ-
ated as to save all cost of transportation of
ores, and enable them to reduce ores at a
greater profit.

DURING the year 1873, ending November,
there were 1,313 recorded train accidents in
the United States, by which 302 persons were
killed and 1,262 injured.

ANTIMONY is selling in England at £51 to
£52 per ton for French Star.

Vein Systems of the Sierra Nevada— Formation and Strike.

[Written for this Press by AMOS BOWMAN.]

The geography of the auriferous slates and
of the granitas, with the relative position of the
axes of elevation and depression bounding
them on the east and west, and the actual posi-
tion of the veins in this golden basin of the
Mesozoic sea, which is now the western slope of
the Sierra Nevada—all instrumentally located,
plotted and presented to a vision undimmed
by any fogs of hypothesis, as in the accompa-
nying map—affords us the first definite idea of
the geological relations of our famous gold
mines.

A zone of extreme flexure, and breakage, of
the auriferous slates, displayed in the mother
lode and its continuations, is shown by the ac-
companying map, to be as near as can be, mid-
way between the axis of greatest uplift of the
main or central summit, and the axis of greatest
depression evinced in the drainage bed of
Sacramento valley, the river itself.

On plotting the veins in their true geo-
graphical position and relation to the mother
lode south, and to the Nevada county and
Sierra county quartz lodes to the northward of
the Amador mine, we see, besides the gen-
eral connection and relationship of worked
veins, a forking of the vein system, which is
displayed alike in the direction of the veins,
and in the geographical position of the vein
regions, where the veins have proved rich
enough to be worked.

The figures on the map designate the mines
which are similarly numbered in the printed
reference list.

As the Sierra Nevada range itself continues
to the northward in two different directions,
northward in the Warner range and Cascade
Mountains of Oregon, and northward in the
La Sen & Shasta Butte culminations, the
forking of the vein-belt and predominating di-
rections of the veins themselves, as here de-
veloped, is not remarkable, nor otherwise than
might be expected.

The diagram in the upper right hand corner
was constructed by laying some tracing paper
over the map, and drawing on it outlines which
included all of the veins that are plotted. By
cutting this out and laying it over that, it will
be found to cover nearly every vein I have lo-
cated, including every vein mine that could be
crowded into the space, for which a United
States mineral survey and patent were, up to
date of plotting, recorded in the office of the
United States Surveyor General, at San Fran-
cisco.

The strike of the slates is, in the main, re-
presented by the general direction of the two
formations printed black, or shaded. Both in
the map, and in the small diagram in the right,
the preponderance of veins keeping company
with the "mother lode" in the same general
direction is made apparent. Several of the
characteristic variations in direction are re-
peated in the little diagram, by way of sugges-
tion as to the probable dynamical cause, or
causes.

The age or origin of these different systems
of fissures, cannot have been precisely the
same. The dynamical cause of one series was
not the same as that of another series. In
general those parallel to each other were formed
at the same time.

The filing of the fissures, with a variety of
minerals, such as we find in the veins, varies
accordingly. Probably the time will come
when the observations of miners touching the
different contents of cross veins, and of geolo-
gists touching the order of uplift,—the longitu-
dinal fractures, the twists and the transverse
fractures of the slates, as they were experi-
enced in different portions of the Mesozoic
basin since it became dry land,—may make out
clearly the priority and exact relations of the
several systems.

The longitudinal fractures represented by
the mother lode were probably the oldest—
telling the story of the uplift of the Sierra.
The twist and transverse fractures which evince
a certain relationship to the northerly and
north westerly trends of the Sierra, will have
to be studied either in connection with the
history of the volcanic peaks, the uplift of the
Cascade Mountains, or the plateau mountains
of Nevada. The mines belonging to these
different systems can be tabulated from the ac-
companying printed list by the miner himself,
and studied to suit his locality.

Classification According to Earth Movement, as Shown by Mountain Uplift.

The totals below show about the proportion
of veins occurring in each system; except, per-
haps, in regard to system No. 5. That might,
to be subdivided, as it represents double the
sweep of horizon of either of the other systems,
including the veins intermediate between the
others in course; both the (a) northeasterly
twists and (b) northwesterly twist fractures.

1.—NORTHEASTERLY FRACTURES, or veins within 15
degrees of the general trend of the Sierra—N16W to N45W
average N30W; embracing a sweep of 30 degrees: 2,
Potts; 3, Kelsey; 7, Arden; 8, Grey Eagle; 15, North-
ern Light; 21, Salathiel; 35, Galena; 38, Sebastopol;
43, Penon Blanco; 49, Greenwood; 52, Oneida; 62, Key-
stone; 66, Spring Hill & Geneva; 87, Newtown; 88, S.
Bright; 89, St. Lawrence; 90, Cedarberg; 114, Rocky
Bend; 126, Geyer; 130, Tecumseh; 136, Wisconsin; 172,
Union; 194, Eureka; 201, Copp; 202, Secret Canon; 212,
El Dorado; 214, Coyote Hill; 215, Talcott; 217, Green-
wood; 233, Cosumnes; 243, Last Chance; 260, Marietta;
268, Empire; 292, Sulphurett; 294, Mahoney; Total, 35.

2.—NORTH-WESTERLY TRANSVERSE FRACTURES, or veins
within 15 degrees of a right angle to the trend of the
Sierra; N45E to N75E; average N60E: 14, Kelly; 23, Ris-

ing Sun; 50, Spring Hill; 97, Noramhaqua; 193, Eclipse;
199, Keystone; 209, Chauleur; 315, Old Pioneer. Total,
8.

3.—NORTHERLY FRACTURES, or veins within 15 degs. of
a northerly trend—N15W to N15E, embracing a sweep of
30 degrees: 22, Norridgegock; 30, Spring Valley; 31,
Venus; 32, Stanton & Allison; 34, Aurora Star; 44,
Rough & Ready; 65, Original Amador; 73, Dry Co.; 74,
Stanislaus; 80, Hancock & Tibbets; 112, Nisbet; 115,
Lone Jack; 120, Stiger; 134, Everlasting; 173, Poorman;
182, Oarson; 184, Wolvstine; 195, Confidence; 198, Yel-
low Jacket; 203, N. Confidence; 211, Shores; 233,
Cosumnes; 242, North Rock; 277, Fort Yuma; 305,
R. Hill; 319, Uncle Sam. Total, 92.

4.—NORTHERLY TRANSVERSE FRACTURES, or veins with
in 15 degrees of a right angle to the northerly trending
axes of uplift; N75E to S75E; embracing a sweep of 30
degrees: 3 & 4, Oaks & Reese, Jones; 39, Epperson; 54,
Slate Ledge; 91, Union; 132, Tyson; 191, Keystone; 226,
Wet Gulch; 233, Ophir; 295, Hancock & Watson,
Total, 16.

5.—TWIST FRACTURES, or veins running from N15E
to N45E (30 deg.); and N45W to N75W (30 deg.); em-
bracing in all a horizon of 60 deg., or as much as 1 and
3 together, the veins of which are neither parallel nor
transverse to either of the principal axes of uplift:
9, Schofield; 45, Eureka; 84, Enterprise; 93, N. Y. Hill;
116, Moorehouse; 124, Eureka; 128, Calaveras; 131,
Bobby Independence; 165, Lincoln; 175,
Sticker; 189, St. John; 204, Butcher Boy; 208, O. Baker;
210, Waters; 219, Green Water; 233, Cosumnes; 249,
Bovee; 251, Crusus; 303, Mammoth; 320, Dr. Hill.
Total, 22.

Contents of Veins in Gold, Silver and Copper.

There are three well defined mineral belts
represented in the veins of the Sierra Nevada,
yielding respectively copper, gold and silver.
For want of space I will not enter into further
details concerning their relations at this time.

Relations to Wealth and Gold.

Not only the largest number of mines, but many
of the great dividend paying gold mines of
California are located in system No. 1. The
Amador paid in 1870 \$341,000, or at the rate of
\$3,410,000 in ten years. The Keystone paid
\$300,000, or \$3,000,000 in ten years. The
Eureka, at Grass valley, belongs to system No.
5. It yielded in 1870 \$672,000, or at the rate
of \$6,720,000 in ten years. The Sierra Buttes
yielded in 1870 \$200,000, or at the rate of
\$2,000,000 in ten years.

Claims Shown on the Map.

The following are references to gold quartz
veins, etc., located by U. S. Mining Patents, in
the U. S. Surveyor-General's office, for
California. The numbers which are shown
on the accompanying map are those of
the patents, having been attached in the order
the mines were patented. The name of claim,
name of patentee and course of vein are given:

- 2 Potts Gold—L. L. Robinson & Hall McAllister, N45W
- 3, 4 Oaks, Reese & Jones—L. L. Robinson & H. McAllister
- 5 Kelsey—Kelsey Co., S120E & S26W
- 7 Arden—P. Superville, A. Gen., N30W
- 8 Grey Eagle—John M. Walker, N45W
- 9 Schofield—W. H. Schofield, N56W
- 13 Kate Kearny—Jas. Johnson, N59W
- 14 Kelly—C. C. Kelly, S57W
- 15 Northern Light—N. Y. Hill, S29W
- 21 Salathiel—Salathiel Co., S9E
- 22 Norridgegock—Norridgegock Co., S124E
- 23 Rising Sun—Rising Sun Co., N74E
- 30 Spring Valley—John M. Walker, S12E
- 31 Venus—Wm. Burling, N12E
- 32 Stanton & Allison—Wm. Watt, N9E
- 34 Aurora Star—Aurora Star Co., N3E
- 35 Galena—R. H. Galena, N12W
- 38 Sebastopol—Wm. Watt, N43W
- 39 Epperson—H. G. Conard, E8W
- 40 Rough & Ready—Rough & Ready Co., S10E
- 43 Eureka—J. D. Treat, N28W
- 49 Penon Blanco—J. T. McLean, S77E
- 49 Greenwood—Greenwood Co., S38E
- 50 Spring Hill & Geneva—A. E. Hill, N5E
- 52 Oneida—C. O. Hill, S12E
- 62 Slate Ledge—Slate Ledge Co., S88E
- 66 Keystone—Keystone Consolidated Co., N2W
- 66 Original Amador—J. H. B. B. Co., N4W
- 66 Spring Hill & Geneva—Spring Hill & Geneva's on. Co., N8W
- 73 Dry Co.—Otto Walter, N2W
- 74 Stanislaus—Gab. E. St. Lawrence, S10E
- 80 Hancock & Tibbets—Geo. Hancock, N2W
- 84 Enterprise—Enterprise Co., N W W
- 85 Newtown Copper—J. McAllister, N27W
- 88 Bright—Samuel Bright, N43W
- 89 St. Lawrence—Robert Doran, N15W
- 90 Cedarberg—John A. Cedarberg, N15W
- 91 Union—Abram Shear, N23E
- 97 Noramhaqua—J. H. B. B. Co., NE
- 99 N. Y. Hill—A. Delano, N5W
- 112 Nisbet—Nisbet Co., NEW
- 114 Rocky Bend—J. H. Rogers, N3W
- 115 Lone Jack—O. W. Wheel, NE
- 116 Moorehouse—Alphonzo Moorehouse, N18E
- 120 Stiger—Geo. W. Simpers, N
- 124 Bangham—Wendell Bangham, N60W N37W
- 128 Calaveras—B. F. Richter, N14W
- 128 Calaveras—Calaveras Co., N18W
- 130 Tecumseh Silver and Copper—Tecumseh Co., N2W
- 131 Bobby Independence—Bobby Independence Co., N2W
- 132 Tyson Iron and Copper—Jas. W. Tyson, N75W
- 134 Everlasting—A. S. Clelland, N30W N11W
- 135 Wisconsin—Wisconsin Co., S20E
- 135 Independence—Independence Co., N65W
- 135 Lucas—D. B. Rodman, N16E
- 172 Union Copper—W. T. Glidden, N45W
- 173 Poorman—E. A. Lewis, N1E
- 175 Sticker—Sticker Co., N45W
- 175 Finnegun—Finnegun Co., S7E
- 182 Oarson—J. C. Scribner, N84W
- 184 Wolvstine—S. O. Putnam, N45W

THE 1,400-foot level of the Consolidated
Virginia is looking better as work is prosecuted.
This mine is expected to begin paying dividends
this month.

Economy in the Use of Quicksilver.

In our issue of April 18th we published an
article on the "Use of Quicksilver in Hy-
draulic Mining," in which we called attention
to experiments recently made by Mr. Hoskin,
of Dutch Flat, with amalgamated lead balls, in
place of quicksilver, in the sluices, thereby
preventing the great loss always incurred by
the latter mode, and which in these days of
famine prices of the metal, is a very serious
one. Referring to this article, we received a
letter this week from Louis Blanding, of the
Cañon Creek gold mine, Nevada county, Cal.,
who says that he was prepared to hear Mr.
Hoskin's experiments gave satisfactory results,
from his own experience and from experiments
lately made by him to test the plan invented by
Mr. Rutherford, of San Francisco, last fall, and
just now perfected by him. It is somewhat
similar in principle to Mr. Hoskin's mode,
although different in application, Mr. Ruther-
ford using amalgamated copper balls in quartz
mills, not flattened, but round, for the reason at
once apparent in the description given below of
the apparatus.

Mr. Rutherford places these amalgamated
copper balls in trays, four or six in number, hav-
ing perforated or screen bottoms; these trays
are fitted in a box, one above another, with a
small space of half an inch or so between the
trays, and are arranged so as to be readily
got at for inspection and cleaning up. Several
of the boxes—two or four or as many
as may be necessary—are placed in position so
that the pulp from the batteries will flow down
through them from one to another, in a suc-
cession of steps. A vibratory motion is given
to the boxes, and therefore to the balls con-
tained in and covering the perforated bottoms
of the trays. The pulp is found to flow readily
over the constantly changing surface of the
amalgamating balls and through the meshes of
the screen without packing or choking; this im-
portant result being due to the stir and agita-
tion of the motion of the balls.

An immense increase of amalgamated sur-
face, with which the gold particles are made to
come in contact, is thus secured by most simple
means, in most compact form, and in an ex-
cellent mode to guarantee saving of the gold.
Very fine gold and floured quicksilver can be
saved in this way, as the surfaces of the balls
are always kept bright by their own attrition,
and free from foreign incrustation or film—so
deleterious, as all mill men know, to amalga-
mation. Mr. Blanding states that one of Mr.
Rutherford's machines for the Cañon Creek
mill has been ordered and shipped and will
soon be in operation.

To test Mr. Rutherford's plan Mr. Blanding
informs us that he has tried experiments with
lead and copper balls and also with balls con-
taining varying proportions of copper and tin—
from four to thirteen per cent. of tin. He
found the best to consist of ninety five (95)
parts of copper and five (5) parts of tin. He
adopted this alloy for the sake of better wear-
ing surface, being sufficiently hard for the pur-
pose, and found no loss in amalgamating ef-
ficiency. Then experiments were made at the
Cañon Creek mill in Nevada county three and
a half months ago and have been repeated with
results far beyond Mr. Blanding's expecta-
tion.

In concluding his letter Mr. Blanding says:
"I entirely agree with you that an exchange of
thoughts among men engaged in the same pur-
suit is always desirable, simply because pro-
vocative of new suggestions and ideas, whence
come all progress and improvement with their
attendant commercial success. This is espe-
cially true of the arts and sciences."

We hope that others of our mill men and
hydraulic miners who have given this subject
much attention, as they all should, will favor
us with any novel plans or methods which
they have found efficient in practical opera-
tions.

THE SIERRA NEVADA MACHINERY.—In speak-
ing of the preparations for erecting the hoist-
ing machinery, etc., for the Sierra Nevada
mine on the Comstock, the *News* states that the
foundation, when finished, will contain 1,700
perch of stone, and the anchor bolts alone will
weigh ten tons, and are so connected and bound
together at the bottom with heavy iron plates
and bars, that no part or section of the work
can give without the whole going together.
The new machinery is arriving by the car-load
daily, and as soon as the necessary timbers can
be got down from the mills, in the mountains,
for the hoisting works building, the erection of
the whole will be commenced and pushed to
completion with all the vigor possible.

A BRILLIANT STUCCO WHITEWASH.—In answer
to an enquiry for a receipt for an improved
whitewash, we are able to give the following,
which is said to be used extensively in Paris
and other parts of France. If tried in this
climate, we should like to hear the result:

Take clean lumps of well burnt lime, slack
in hot water in a small tub, and cover it to keep
in the steam; it should then be passed through
a fine sieve in a fluid form, to obtain the flour
of lime. Add a quarter of a pound of whiting
or burnt alum; two pounds of sugar; three
pints of rice flour, made into a thin, well-hoiled
paste; and one pound of glue dissolved over a
slow fire. It is said to be more brilliant than
plaster of Paris, white, and will last fifty years.
It should be put on with a paint brush.

The BLACK represents slates predominating and granite in spots. The LIGHT SHADING represents granites predominating and slates in spots.
NOTE.--This map shows the location and course, by instrumental survey, of 200 gold mines in the Jurassic, etc., slates of California, to which U. S. Land Patents have been granted.

Diagram of VEIN ZONES and VEIN SYSTEMS.

Quicksilver at Vienna.

In a review of "Metals at the Vienna Exposition," *Engineering* speaks as follows of the exhibits of quicksilver:

The exhibits of mercury were not numerous. In the department of Spain we met with a good mineral collection from the mines of Almaden, and of their metallurgical products by Francisco de Avila, of Madrid. The district of Almaden, near Ciudad Real, consists of the Silurian formation, containing hard sandstones with bituminous clay slates and beds of limestone and greywacke, with numerous fossils in its upper section. The bituminous slates or shales are traversed by three lodes, the known length of which is over 100 fathoms. Their width is on an average 21 feet, but in some instances increases to 40 feet. The two lodes, San Francisco and San Nicholas, approach to within three feet or four feet of each other for some distance, and are then worked together. The rock is rather weak, and the mines must be secured to a great extent by arches of stone or bricks, of which one, at a depth of 800 feet, has a span of 67.5 feet. The annual produce of these mines is equal to 32,000 hotties, or about 2,432,000 pounds of mercury. The raw ore is mixed with carbonate of lime, quartz and clay slate, and is hand-picked into four classes, containing about 50, 30, 15 and eight per cent. of metallic mercury. It is introduced in vertical kilns, closed on the top, and heated from underneath for 20 hours with brushwood, when the metallic mercury passes off through openings in the sides into condensing pipes, made of clay, and at last into condensing chambers. Each charge is finished after three days, when the mercury is collected and drawn off from the condensing pipes. This operation was illustrated at Vienna by models of the furnaces and samples of ore, mercury and slags.

From Italy

We found samples of mercury ore or cinnabar, shown by Dominico Paradisi, from the mines of Siale, near Siena, and from those of Vallalta, near Agordo, in Lombardy. The latter ore is an intimate mixture of clay slate, porphyry and bituminous clay, containing from one to 60 per cent. of mercury, imbedded in an irregular form in graphitic clay slate of the lower carboniferous period. The ore is heated in kilns with a wood fire, and the vapors of mercury are condensed and collected in wooden laundries. The annual produce is about 35,000 pounds; 136 men being employed.

France

Also exhibited samples of cinnabar from Mimoun and Raaz-el-Maa, in the province of Constantine, and Austria, from Knapouse and Idria, in Caruiola, from which latter place, in 1872, 766,600 pounds of mercury were produced.

The Mines of Idria

Were discovered in 1497, and still give employment to 553 miners, and over 200 men at the dressing and smelting works. The principal ore deposit is again a black, bituminous, almost graphitic slate of the lower carboniferous formation, varying from 10 to 30 fathoms in thickness; it rests upon limestone, and is covered by a limestone conglomerate, bituminous shale and sandstone, the latter of Triassic age. The ore bed is explored for 400 fathoms in length, and 146 fathoms in depth, and in 1867 was estimated to hold nearly half a million hundredweights of mercury within 156,000 cubic fathoms of ore ground, the average being two per cent. The mines are opened by five shafts, with pumping and drawing machinery, driven by steam and water-power. The ore is carefully hand-picked, and classified into rich ore, with 10 per cent., and into lumps and smalls, with 1.5 per cent. of quicksilver. The former is subjected to a distilling process from closed retorts, the latter to such an operation in kilns and in reverberatory furnaces, with admission of air. The metallic fumes are condensed in condensing pipes and chambers, and a great part of the metal is reconverted into cinnabar by amalgamating it with pure sulphur in rotating casks. The sulphide of mercury thus obtained is subjected to a process of sublimation, which yields crystalline cinnabar, with a beautiful vermilion color, after being ground to a fine powder. The Idria Works exhibited a collection of minerals, fossils, ores and metallurgical products, including an iron basin containing 15,000 pounds of quicksilver, and the mines and smelting works were also suitably illustrated by geological maps and drawings, showing the improvements that had been introduced of late years, principally for a better condensation of the fumes.

In the exhibition of Turkey we noticed a sample of cinnabar from the vilayet of Janina, and in the collection of Professor Kustel a specimen of metacinnabarite, from Redington mine, in California, while the other great quicksilver mine of California, viz., New Almaden, New Idria, Lake mine, Guadalupe and others, which produce about 3,500,000 pounds annually, were entirely unrepresented, and the once-celebrated mine of Santa Barbara, at Huancavelica, in Peru, which formerly yielded the greater part of the mercury which was used in amalgamating silver ores in South America and Mexico, appears to have been quite abandoned since the discovery of the mines in Upper California. There is no doubt that this discovery was a cause of paramount importance for the rapidly-increasing production of precious metals, and the consequent colonisation of the west coast of America.

Lancha Plana Coal Mines.

The principal coal mine in the vicinity of Lancha Plana is the one owned and worked by Waddell & Murray, residents of Lancha Plana. This mine is situated about one mile north of Lancha Plana, and is in a tract of land containing 160 acres, belonging to the parties mentioned above. On the tract there are three distinct seams of coal, and up to the present time the width of these veins has not been determined, for although drifts have been run a long distance on each side of the tunnel, there is no appearance of the veins giving out. The manner in which this mine has been worked is as follows: A tunnel has been driven a distance of 280 feet in length, which, for some distance, has an incline of one foot in four, for the purpose of intersecting the different veins up to the present time found in the tract. The first vein, which is seven feet in thickness, was struck one foot from the mouth of the tunnel. After driving through this vein a layer of sandstone was penetrated some eight feet thick, and upon going through this the second vein was found. This vein proved to contain a better quality of coal than the first, and was eight feet in thickness. Between this vein and the third one there is another layer of sandstone seven feet thick. At present the thickness of this vein has not been determined, as from this point the tunnel was run the remaining distance on a level. The probability is, that if the quality of this vein improves in the same ratio as the former ones, the coal derived therefrom will prove to be the finest yet found in the State. The coal found in this mine has been proved to be excellent material for blacksmithing purposes. It burns well, and makes steam as quickly as the best wood.

About one and a half miles north of the Waddell claim, Mason has discovered, by means of boring, a large body of coal, proving that the Waddell claim is a permanent and extensive mine. Between the Mason and Waddell claims is a place called China Gulch, situated on the Waddell tract, and about a quarter of a mile from the mouth of the tunnel. In this gulch some very fine ore has been discovered, and as the company intend to sink a shaft in the gulch some very interesting developments can be reasonably expected. From all appearances, the formation in this locality is older than the veins in the tunnel, while the surface boring exhibits coal very hard and firm. It is maintained by practical coal miners that the Lancha Plana is darker, harder and more free from dirt than the Lone coal. The residents around Lancha Plana are very anxious for the building of the Stockton and Lone Railroad; for until that enterprise is consummated these extensive coal fields will be comparatively worthless.—*Sutter Creek Independent*.

Raymond & Ely.

The *Pioche Record* of a late date speaks as follows of the Raymond & Ely mine: Yesterday there were a number of assays made from rich ore taken from the old Pioche-Phoenix claim, but of course one swallow does not make a summer, and a good many assays of rich ore would neither make a large or a profitable vein. In the workings of the past week, the 1,200-ft. level is advanced to 73 feet. The tenth level is looking somewhat better. The ledge in the face, though not large, shows some extremely rich ore, but yet there is not enough of it to warrant any particular felicitation. Nevertheless, in spite of all the discouraging events of the past few weeks, the condition of the Raymond and Ely is full of anticipations for improvement. The ledge struck in the Page & Panaca is certainly an extension of the old Raymond & Ely vein, and shows that despite of cross-head and interposing ravine, and all other sources of disturbance, that it was still there. This is one of the most charming indications now revealed by the condition of the mines as is known. In the 1,200-ft. level the cross-cut is being pushed as rapidly as possible. It is now in 73 feet and is expected to cut the ledge in about 125 or 130 feet from the shaft. This is just on the water level and many prophecies are made of the condition of the vein when reached. Of course no one knows what that will be, and probably one's hopes are father to the thought, but still if the Raymond & Ely vein shows big, this same Pioche of ours will have a good time.

MEXICAN MINES.—A correspondent of the *Bulletin*, writing from Mazatlan, speaks of business in that town being very much paralyzed on account of the ravages of small-pox. He says that under these circumstances the only mining interests are kept alive, much machinery being sent to the interior and ore being shipped in large quantities. The statistical report from Durango mentions that during last year 162 mines were denounced in said State; that 81 more were registered, and 119 mines were taken possession of to be regularly worked. In most of the other Mexican States, a similar activity is visible; and besides gold and silver, much attention has lately been paid to other minerals. Quicksilver, copper, iron, coal, marble and alabaster, the latter being principally explored in the State of Puebla, where a company has been formed, extracting among other fossils also the beautiful Teacah, or Mexican onyx, so much appreciated in Europe. Large quantities of the splendid Mexican opal, have also been brought to the City of Mexico.

WORKS for the smelting of zinc and the manufacture of fire-brick and fire-clay retorts have been established at Cherokee, Kansas. The capital invested came from Chicago.

Borax in California.

The *Inyo Independent* has the following of this product of our State:

Quite an excitement was created some months since by the discovery of reported extensive borax deposits in the southern borders of this county. Something like a hundred and fifty quarter sections of borax lands were located, but subsequently most of them were abandoned, it appearing that the quantity of crude material obtainable was not sufficient to justify further prosecution of this industry. But little has been heard of the business in that section since, and it has been deemed of little promise.

But notwithstanding all this, a number of lucky and enterprising locators have been all the time quietly at work, and with rude and most temporary facilities have been producing on the average about half a ton per day of the best quality of borax. Right in the midst of a lake bed of Slate Range, thirty-five miles west of Indian Wells, there are some seven quarter sections of land where the horate of soda (not lime) is found in inexhaustible quantities, while the ground to a depth of a foot or more is so full of the horate as to be spoken of and considered as a bed of horax a foot thick.

The marketable article is obtained in three ways: By evaporation of the water heavily impregnated with it, by working the earth containing the horate of soda, and from extensive deposits of the pure article. After the surface of the ground has been scraped clean, another deposit soon takes place, and altogether these borax mines are considered practically inexhaustible.

Wednesday last two gentlemen, J. W. Searles and J. D. Creigh, as company representatives, made application to the Land Office here for four different United States patents, covering 160 acres of these lands. From these gentlemen we learn that work is to be henceforth prosecuted at their works on a scale equal to six tons per day. Besides a few white men, they are now employing eight Chinamen and expect to increase the number.

The San Francisco market price of borax is twelve cents per pound, and as the freights are comparatively cheap from Slate Range, quite a handsome income will be derived from its production, especially at the rate of five or six tons per day. We are indebted to these gentlemen for specimens of the manufactured article and also of natural crystals of equal size, scarcely distinguishable one from the other. These gentlemen feel confident that the business of their mine is going to be an item of no small importance in the commerce of Southern California, and we do not doubt it in the least.

CO-OPERATIVE SHIP-BUILDING TO BE TESTED.—The *Vallejo Chronicle* details the following as the result of the movement to commence ship-building by co-operation in Vallejo: This morning ten or twelve of our best mechanics met together to discuss the proposition of forming an association to build a vessel. The matter was thoroughly canvassed, and the most feasible means of carrying out the enterprise well considered. The universal opinion was that it was eminently practicable; and the determination was made to form an organization and commence work. The system of operation agreed upon is as follows: The association will be composed of about a dozen of the best workmen, who will assume all the responsibilities, and be the real builders of the vessel. These men will, of course, stick by the work of construction until the vessel is built, whatever may occur. This association will, however, employ such other workmen as the necessities of the work may require; the workmen thus employed agreeing to wait for their pay until the vessel has been sold. The assurance was conveyed to those present at the meeting that there were business men here who would furnish all the materials necessary for a vessel and wait until its sale for their money. The description of the vessel to be built was fully discussed; some favoring the construction of a ship, so great was their confidence in the success of the enterprise. The general disposition, however, seemed to favor the construction of an outside schooner of about 300 tons burden. As the present enterprise is a trial experiment, the latter design seems to be a trial well as safest. An agreement was then drawn up by those present, setting forth that the subscribers would build a vessel at Vallejo, the character and dimensions thereof to be hereafter decided. The members are now engaged in inspecting the beach to determine the best location for the construction of the contemplated vessel.

EUREKA MINES.—The *Sentinel*, of April 12th, speaks of the mines of Eureka district, of the Richmond in particular, as follows: The specie production of the States and Territories of the Pacific coast during the past year is, in round figures, \$72,700,000. Of this large amount, Nevada alone yielded \$35,350,000, or nearly one-half, while California gave only \$18,225,000, thus falling short of the yield of the previous year by \$1,000,000, while the product of Nevada was augmented \$10,000,000. To this vast increase Eureka district has most grandly contributed. The Richmond alone has produced the astonishing amount of 600,000 ounces of silver, 32,000 ounces of gold, in addition to 5,000 tons of lead; footing up, probably, about \$2,000,000 altogether, while the product of the remaining four lullion-producing companies would most likely not fall far short of \$3,000,000 more, or \$5,000,000.

Gold Hill and Virginia City.

Virginia City and Gold Hill, whose unification is now well nigh completed, continue, taken together, one of the most remarkable boroughs to be found anywhere on the continent. The many novel sights to be witnessed on the streets and thoroughfares of our cosmopolitan abiding place are a never-failing source of wonderment to the chance visitor. The lengthy procession of quartz teams, consisting of from 12 to 18 animals each, driven by a single muleteer, wending their way to the music of bells from the mines to the mills, with their heavy loads; the moon-eyed Celestials, hawking wood about the streets by the donkey-back load; Indian mahales, strolling along with their papposes closely ensclosed in willow baskets of ancient style of manufacture; next, a Broadway 'bus or a 'prairie schooner'; then great crowds of miners, hurrying to their work, armed with well-filled dinner-buckets and dangerous-looking candlesticks—all these sights, and many others which we have no time to enumerate, constitute objects of interest to a tourist. Ours, too, is a busy community. Day and night, week-days and Sundays, the noise from hoisting-works and quartz-mills is heard perpetually; while over the somber-looking city hovers the smoke and steam generated by huge furnaces required to move machinery of herculean proportions. Creeping up the steepgrade leading to our mountain home are to be seen trains of cars, constantly arriving. From the summit of the Sierras, water, distilled from snow, is brought to our midst across a valley and up a steep mountain, a distance of 30 miles, by means of an inverted mammoth siphon. Everywhere about us are to be seen traces of a heroic conflict of man with nature—roads built in apparently impassible localities, mountains removed, and millions upon millions of treasure wrested from the bowels of the earth. Virginia and Gold Hill can boast a cosmopolitan population. In the mines, along the sidewalks, and in places of public resort, are to be found, indulging in Babylonish jargon, representatives of all nations. The shadows from Mount Davidson at evening rest upon a queenly city, a more prosperous one than which, considering its size, is not to be found elsewhere in the Union.—*Gold Hill News*.

THE GUIANA MINING BUBBLE.—We received a call yesterday from Mr. L. C. Kerrick, who returned to Salt Lake yesterday, one of the victims of the exploded Guiana bubble. He left this city January 1st, and sailed from Salem on the 10th. A twenty days' journey by sea brought him to the South American Ophir, where the golden sands were to be found of fabulous richness. Twenty miles from the seaport, he, with anxious miners, arrived at the placer mines. The oppressive humidity of the atmosphere quite unfit the white man for work; all mining industry is performed by coolies. A very brief experience revealed to all these fortune hunters that they had been egregiously sold. The pay dirt, where found, yielded seven cents to the pan; the coolies would not work diligently, provisions and supplies were enormously high, health gave way under the noxious climate, and homesickness took possession of all. Mr. Kerrick tells us that about seventy-five of our Utah boys were tempted from the rich mines of our Territory to follow after this Will-o'-the-Wisp; the larger proportion of whom had used the precaution to take means with them to bring them back in case of disappointment. It required but a few weeks to sicken them of their new field of labor, and one by one they folded their tents like the Arab and silently stole away. A bird in the hand is worth a whole covey in the bush.—*Salt Lake Tribune*.

COKE.—Col. Lewis, of the Pancake coal mine, arrived in town last evening, bringing with him specimens of coal from the mine, which had been converted into coke. The piece examined by us appears the same as produced in other places, and will doubtless meet the requirements of the furnace. If a sufficient quantity of coal, from which the extraneous matter can be extracted by charring, is obtainable from this mine, the Pancake company will prove a very profitable enterprise, both to the owners and the mine, as the freight would be considerably decreased, amounting to almost nothing, when compared to railroad and teaming charges on the supply coming from Pittsburg, San Francisco and other places. The mine is at present 225 feet down and the water level not yet reached. Coal of a superior quality is now being extracted. The new and powerful machinery recently erected is in working order, and everything pertaining to the successful development of the mine progresses finely.—*Eureka Sentinel*.

RICH GRAVEL DIGGINGS DISCOVERED.—We are informed that a very extensive body of rich gravel has lately been discovered under the hills between this place and the Mountain Spring House, and that a tunnel is now being run in under the toll road, a short distance this side of the last named place, by some parties who have already struck the gravel bed, which is reported to be very rich. The full extent of the bed is not positively known, but if it extends under the whole ridge, as is generally believed, it will be one of the most valuable "strikes" that has been made in this county since the flush days of '49.—*Amador Dispatch*, April 18th.

THE hardy sons of toil composing the Virginia Miners' Union will have a grand picnic to Washoe valley on the 8th day of August next.

DEWEY & CO.**American & Foreign Patent Agents,**

OFFICE, 338 MONTGOMERY STREET, S. F.

PATENTS obtained promptly; Caveats filed expeditiously; Patent reissues taken out; Assignments made and recorded in legal form; Copies of Patents and Assignments procured; Examinations of Patents made here and at Washington; Examinations made of Assignments recorded in Washington; Examinations ordered and reported by Telegraph; Rejected cases taken up and Patents obtained; Interferences prosecuted; Opinions rendered regarding the validity of Patents and Assignments; every legitimate branch of Patent Agency Business promptly and thoroughly conducted.

Our intimate knowledge of the various inventions of this coast, and long practice in patent business, enable us to abundantly satisfy our patrons; and our success and business are constantly increasing.

The shrewdest and most experienced Inventors are found among our most steadfast friends and patrons, who fully appreciate our advantages in bringing valuable inventions to the notice of the public through the columns of our widely circulated, first-class journals—thereby facilitating their introduction, sale and popularity.

Foreign Patents.

In addition to American Patents, we secure with the assistance of co-operative agents, claims in all foreign countries which grant Patents, including Great Britain, France, Belgium, Prussia, Austria, Victoria, Peru, Russia, Spain, British India, Saxony, British Columbia, Canada, Norway, Sweden, Mexico, Victoria, Brazil, Bavaria, Holland, Denmark, Italy, Portugal, Cuba, Roman States, Wurtemberg, New Zealand, New South Wales, Queensland, Tasmania, Brazil, New Grenada, Chile, Argentine Republic, AND EVERY COUNTRY IN THE WORLD where Patents are obtainable.

No models are required in European countries, but the drawings and specifications should be prepared with thoroughness, by able persons who are familiar with the requirements and changes of foreign patent laws—agents who are reliable and permanently established.

Our schedule prices for obtaining foreign patents, in all cases, will always be as low, and in some instances lower, than those of any other responsible agency.

We can and do get foreign patents for inventors in the Pacific States from two to six months (according to the location of the country sooner than any other agents.

Home Counsel.

Our long experience in obtaining patents for Inventors on this Coast has familiarized us with the character of most of the inventions already patented; hence we are frequently able to save our patrons the cost of a fruitless application by pointing them to the same thing already covered by a patent. We are always free to advise applicants of any knowledge we have of previous applications which will interfere with their obtaining a patent.

We invite the acquaintance of all parties connected with inventions and patent right business, believing that the mutual conference of legitimate business and professional men is mutual gain. Parties in doubt in regard to their rights as assignees of patents, or purchasers of patented articles, can often receive advice of importance to them from a short call at our office.

Remittances of money, made by individual inventors to the Government, sometimes miscarry, and it has repeatedly happened that applicants have not only lost their money, but their inventions also, from this cause and consequent delay. We hold ourselves responsible for all fees entrusted to our agency. The principal portion of the patent business of this coast has been done, and is still being done, through our agency. We are familiar with, and have full records, of all former cases, and can more directly judge of the value and patentability of inventions discovered here than any other agents.

Situated so remote from the seat of government, delays are even more dangerous to the inventors of the Pacific Coast than to applicants in the Eastern States. Valuable patents may be lost by the extra time consumed in transmitting specifications from Eastern agencies back to this coast for the signature of the inventor.

Confidential.

We take great pains to preserve secrecy in all confidential matters, and applicants for patents can rest assured that their communications and business transactions will be held strictly confidential by us. Circulars free.

Engravings.

We have superior artists in our own office, and all facilities for producing fine and satisfactory illustrations of inventions and machinery, for newspaper, book, circular and other printed illustrations, and are always ready to assist patrons in bringing their valuable discoveries into practical and profitable use.

DEWEY & CO.,

United States and Foreign Patent Agents, publishers Mining and Scientific Press and the Pacific Rural Press, 338 Montgomery St., S. E. corner of California St., San Francisco.

The Mining & Scientific Press.

Started in 1860, is one of the oldest weekly journals now published in San Francisco. It has been conducted by its present proprietors for ten years, during which period it has been repeatedly enlarged and constantly improved. The active and steadfast efforts of its publishers have gained for its conduct an amount of practical experience greater than any other publishers have accumulated on this coast, of a weekly journal.

The sum paid by us for the best editorial talent obtainable for our special class journal for engravings, for interesting news and correspondence, and for printing a large-sized, handsome sheet, is unequalled by that of any other American weekly west of the Mississippi. As a PRACTICAL MINING JOURNAL it has no rival on this Continent.

It is the only MECHANICAL, and the only SCIENTIFIC journal of the Pacific States.

Every Miner, Assayer, Millman, and Metallurgist in the United States should take it.

Every Pacific Coast Mechanic, Engineer, Inventor, Manufacturer, Professional Man, and Progressive and Industrial Student should patronize its columns of fresh and valuable information.

Every Mining Engineer, Superintendent, Metallurgist, Millman and the Worker in the wood should profit by its illustrations and descriptions of New Machinery, Processes, Discoveries and Record of Mining Events.

Every intelligent thinker in the land, in high or humble situation, who would avoid literary trash for genuine information, should SUBSCRIBE AT ONCE.

DEWEY & CO.,

No. 338 Montgomery street, S. F.

A Good Binder for \$1.50.

Subscribers for this journal can obtain our Patent Elastic Newspaper File Holder and Binder for \$1.50—containing gilt titles of the paper on the cover. It preserves the papers completely and in such shape, that they may be quickly fastened and retained in book form at the end of the volume, and this binder (which is very durable) used continuously for subsequent volumes. Post paid, 25 cts. extra. It can be used for Harper's Weekly and other papers of similar size. If not entirely pleased, purchasers may return them within 30 days. Just the thing for libraries and reading rooms, and all who wish to file the Presses. lamp

GRAND INDUSTRIAL EXHIBITION,

To be held under the auspices of the

MECHANICS' INSTITUTE

OF SAN FRANCISCO, CALIFORNIA.

Opening on August 18th, 1874.

The Board of Managers herewith announce that a grand Industrial Fair will be held in the city of San Francisco for 30 days, opening on August 18, 1874.

In view of the increasing commercial and manufacturing importance of San Francisco, its contiguity to and close connection with the various countries bordering on the Pacific, the managers have constructed a Pavilion having a floor area of 150,000 feet, and have invited to it all who are disposed to come and exhibit. All exhibitors will be placed on the same footing. Motive power will be furnished free.

The building will be open day and evening, and every facility will be extended to exhibitors and visitors.

Application for space must be made without delay to the Secretary of the Board of Managers, 27 Post street, San Francisco, and all inquiries will be answered and information extended promptly.

No space can be secured unless applied for before the 20th of July next. A. S. HALLIDIE, Pres. J. H. CULVER, Sec'y.

SHEET IRON PIPE.

THE

Risdon Iron and Locomotive Works

Corner Howard and Beale Streets,

Are prepared to make SHEET IRON AND ASPHALTUM PIPE, of any size and for any pressure, and contract to lay the same where wanted, guaranteeing a perfect working pipe with the least amount of material.

Standard sizes of railroad Car Wheels, with special patterns for Mining Cars. These small wheels are made of the best Car Wheel Iron, properly chilled, and can be fitted up with the improved axle and box—introduced by this company, and guaranteed to outlast any other wheels made in this State.

All kinds of Machinery made and repaired.

24v22-3m JOSEPH MOORE, Superintendent.

The Mining Committee in Congress.

The opinion was expressed in our last issue that Senator Jones, of Nevada, recently appointed on the Committee of Mines and Mining, in Congress, should not have been placed on that Committee, in view of the personal interest he had in the issue of the Mining Bills now being considered by the Committee. That the point was well taken is proven by subsequent developments. A dispatch to the daily papers, dated Washington, April 27th, says:

The Senate Committee on Mines and Mining held a meeting to-day for the purpose of further considering the so-called Sutro Tunnel amendments, which were attached by the House of Representatives to the supplemental Mining Bill. Sutro and his counsel, Judge Jeremiah Black, were present. Sutro, having obtained permission to address some questions first to members of the Committee, inquired of Senator Jones whether he (Jones) had not a personal pecuniary interest in a decision of the matter in controversy, and Jones frankly admitted that as a part owner of the Comstock Lode he had such an interest. Sutro next obtained from Sargent a candid admission that he (Sargent) had heretofore formed and expressed an opinion hostile to Sutro, and proposed amendments to the bill. Sutro then suggested that the Mining Committee should refer the matter to some other committee of the Senate, composed entirely of unbiased Senators. The Committee having cleared the room for private consultation, decided by a vote of 4 to 3 to comply with the suggestion, and accordingly referred the bill, with the amendments, to the Senate Judiciary Committee for advice as to the proper decision of the legal questions involved.

On the next day the Senate Committee on Mines and Mining reported back the Mineral Land Patent Bill, with the amendments, requesting to be discharged from a further consideration of the matter, and desiring that the bill be referred to the Judiciary Committee. No objections were made. Senator Sargent simply stated that the Mining Committee should have reported the merits of the bill, but he hoped the Judiciary Committee would report on the facts as well as the law.

On the motion to refer the bill back to the Senate, Messrs. Tipton, Harvey, Goldthwaite and Alcorn voted in the affirmative, and Hamilton, Sargent and Jones in the negative. Senator Sargent's representation as having been very indignant at the action of the Committee, while Jones was compelled to acknowledge that he was interested.

We can see no impropriety in the action whatever. Senator Jones was so directly interested that he would have been unable to give an unbiased opinion of the matter, which is important to others as well as himself. The amendments should be discussed dispassionately by people who have no direct personal interest in the issue, in order that justice should be done to all parties. There are two sides to a question, and in this particularly there is a great difference of opinion between the rich and the poor men. If the rich men are to decide it, they will decide it their way, and if the poor men are to decide it, they will decide it their way. Therefore people not directly interested ought to judge more calmly what is best for the majority.

The views expressed by us in our last issue were those of the miners owning mines to the eastward of the big mines on the Comstock, and the common miners generally. It is unnecessary for us to repeat the remarks made in the previous article, but we are happy to see that our position was the correct one, more especially as our cotemporaries who mentioned the matter spoke of Senator Jones as the best man for the place, not thinking of his being so much interested in a matter being considered by his committee. The mining bills will shortly be settled, one way or another; but we hope that no mining laws will work hardship to the common miners of the Coast.

A VALUABLE MINERAL SPRING.—The *West Coast Star*, of Mendocino City, reports the discovery of a mineral spring, near Little Lake, which is thought to possess valuable medicinal qualities. It is claimed that important benefits have already been derived from the use of its waters, in several cases of chronic diseases, skin diseases, bilious cramps, neuralgia, dyspepsia, etc. The spring is owned by Mr. H. L. Norton, who is about to erect buildings for the accommodation of visitors and invalids, and such as with its natural attractions will make it a desirable watering place. Dr. L. Lanzweert has furnished the following report on a sample of the water sent him for analysis.

The water contains 99.28 grains of solid matter to the gallon, consisting of Chloride of sodium, 62.00; borate of soda, 11.76; carbonate of lime, 7.20; carbonate of iron, 2.08; silica, alumina, 2.64; organic matter, traces; free boracic acid, 10.00.

NEW SMELTING WORKS.—The Sacramento smelting works are completed, and actual operations will be commenced in them on Saturday, the 6th. The President, Secretary and Superintendent of the company have gone on a visit to the mining districts of Nevada and Utah, to purchase ore and establish ore purchasing agencies. They are supplied with a large amount of capital for this purpose.

PATENTS & INVENTIONS.

A Weekly List of U. S. Patents Issued to Pacific Coast Inventors.

[FROM OFFICIAL REPORTS FOR THE MINING AND SCIENTIFIC PRESS, DEWEY & CO., PUBLISHERS AND U. S. AND FOREIGN PATENT AGENTS.]

By Special Dispatch, Dated Washington, D. C., April 28, 1874.

FOR WEEK ENDING April 14, 1874.

LEATHER SHAVER.—Augustus H. Beschormann, S. F., Cal.

REFLECTING LAMP.—Emil Boesch, S. F., Cal.

MACHINE FOR RIVING SHINGLES.—Daniel Shankland, Watsonville, Cal.

ORE CONCENTRATOR AND WASHER.—Jonas' B. Wilder, Sonora, Cal.

CAR COUPLING.—Alexander Wonderly, Palisade, Nevada.

MACHINE FOR BLUESTONING SEED GRAIN.—John Wilkie, Yuba City, Cal.

WINDMILL.—Corydon A. Fargo, Modesto, Cal.

AUXILIARY HEATER FOR STEAM FIRE-ENGINE.—Absalom B. Hallock, Portland, Oregon.

STEAM MINING PUMP.—Andrew M. Rogers, Central City, Colorado.

SHAFT COUPLING.—Wm. J. Silver, Salt Lake City, Utah.

PUMP VALVE BOX.—Wm. J. Silver, Salt Lake City, Utah.

The patents are not ready for delivery by the Patent Office until some 14 days after the date of issue. NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & CO., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest time possible.

SUTRO TUNNEL.—On the 18 ult. shaft No 2 of the Sutro tunnel was finished to the tunnel level. Its depth is 1,040 feet. It has been sunk 227 feet from the eighth of January, besides cutting a 10x10 station 35 feet long with the excavation of ground for a tank 16x12. The *News* says that in a short time a header will be started from the bottom of this shaft in both an easterly and westerly direction. A powerful pumping engine, of sufficient capacity to raise thirty inches of water every twenty-four hours, will be placed at the bottom of this shaft.

ILLUSTRATE YOUR INVENTIONS.—It is hardly possible to introduce successfully an improvement in machinery of any class without the aid of a good engraving. It not only serves to show at a glance the valuable features of the machine more effectually than the longest verbal description can do, but it also constitutes the very best method of advertising an invention, its attractive appearance securing the attention of the reader, while a column of reading matter, without illustration, might be overlooked. —*National Car Builder.*

ARCTIC EXPEDITION.—It is announced that the American Geographical Society will be represented at the Millian celebration in Iceland by Dr. Hayes, the distinguished Arctic explorer. He will sail for England about the first of June, and leave Dundee for Iceland in a vessel chartered for that purpose, about June 20th. He will explore parts of Iceland never before visited, and be accompanied by several Professors.

TEMPERING DRILLS.—It is stated that Mr. Knecht, the engineer of the St. Gothard tunnel, has discovered a means of tempering drills for rock-boring machinery, by which they are rendered as hard as diamond, whilst at the same time they do not become brittle. The invention, it is believed, will result in the St. Gothard tunnel being pierced a year or two in advance of the expected date.

ARIZONA MINES.—Prospecting parties are constantly leaving Tucson for the mountains, and the new discoveries and rich specimens that are coming in indicate that the opinion of those who have been most sanguine of the mineral wealth of Arizona will be more than realized.

BULLION SHIPMENTS.—Wells, Fargo & Co. shipped last week, says the *Battle Mountain Measure for Measure*, thirty-seven bars of silver bullion from Austin, valued at \$48,000, and seven bars from Belmont, valued at \$8,000, making a total shipment of forty-four bars, with a total value of \$56,000.

CHEAPER WATER WANTED.—The miners of Moore's Flat, Nevada county, have struck for a reduction in the price of water. They want water at 8 cents per inch. The price heretofore has been 12½ cents.

LAND COMMISSIONER.—The President has nominated Samuel S. B. Brndett, of Missouri, Commissioner of the General Land Office, vice Drummond, resigned.

The Yuba and Feather rivers are very full, the warm weather lately having caused the snow in the mountains to melt rapidly.

The Abbot Quicksilver Co. has removed its principal place of business to Colusa from this city.

GUERNEVILLE, Sonoma county, is very much excited on the subject of quicksilver mining. A district has been formed called the Guerneville Mining District, and N. E. Manning elected Recorder. The excitement is so great that the hands at the saw-mill all left and went prospecting, so the mill was shut down.

The Carson *Appeal* says the town of Empire is busy in every department. The mills have all the ore they can reduce, and all the water and wood they want, and are running at full capacity. The Carson river is yet in its banks.

The mills are all in full blast along the Carson river and on all the cañons. As yet, the wagon-roads are not in first-rate order, but the teamsters manage to haul sufficient ore to the outside mills to keep them in operation.

The Mechanics' Institute Fair building will shortly be commenced. The bids were opened on Friday and the contracts will be awarded on Monday, so that work on the building will be started immediately.

STRATTON BROS. are engaged in raising by hydraulic power a four story brick building on California street. The building has a frontage of 40 feet, and is being raised so that the cellarage will be available for business purposes.

The imports of silver ore into Liverpool in March amounted to 360 tons, and of silver-lead ore about 130 tons.

TWO HUNDRED and twenty-two tons of rock recently crushed at the San Bruno mine, Calaveras county, yielded \$55.50 per ton.

Each issue contains sixteen well filled pages, Original and Choice Engravings, Editorials on Home Industries, On various kinds of Stock-rearing, On Horticulture and Gardening, Correspondence from Farming Districts, Answers and hints to Correspondents about Local Farming, Good Health and Useful Information, Reports from Granges and Farming Clubs, Mechanical and Scientific progress, Agricultural Notes from all quarters, Domestic Produce Markets, Home Circle, Domestic Economy, Mechanical Hints and Domestic Receipts, Home and Farm Matters. Affording, in all, more of real instructive and profitable matter for general readers than any other weekly on this side of the Continent.

The Ward mining bill, which was first referred to the Committee on Public Lands, and afterwards to the Committee on Mines and Mining in Congress, is still in the hands of the latter committee. It is to be hoped that the bill will be killed when again brought before the House; and no doubt the Pacific Coast delegation will do their best to give it a quietus.

More mining will be done this year in West Point District, Calaveras county, than in the last ten years. The success attending deep excavations has given a permanent impetus to quartz mining in that section.

The Crown Point 1,400 foot level is opening out splendidly and the fine ore body recently developed by the east drift is now nearly 60 feet wide, being twice as wide as on the level above, and no east wall reached as yet.

A FORTY-TON furnace has been put up on the Buena Vista mine, San Luis Obispo county, and three tanks of quicksilver produced at the first run.

Five hydraulic claims are at present working in the vicinity of Mokelumne Hill and are paying well.

CINNABAR City is the name of a new town near the Amador quicksilver mine, El Dorado county.

The Summit shaft of the Meadow Valley mine at Pioche is down 1,014 feet.

MINERS are beginning to migrate from the various northern towns of Oregon.

BULLION shipments from the Raymond & Ely mine on April account aggregate \$62,400.

A MUSTARD plaster is the latest and instant cure for poison oak.

The Silver Hill hoisting and pumping works are again in full blast.

The busy season at Eureka is now fairly inaugurated.

CONCENTRATION WORKS are to be erected at Granite, Colorado.

A NEW BOOK.

SECOND EDITION—REVISED AND ENLARGED.

The Explorers', Miners' and Metallurgists' Companion.

Comprising a Practical Exposition of the Various Departments of Exploration, Mining, Engineering, Assaying, and Metallurgy.

Containing 672 Pages and 83 Engravings

BY J. S. PHILLIPS, M. E., Of California, a Practical Operator for Thirty-four Years: Explorer and Resident of the Pacific States and Territories for the last Eight Years.

PRICE, bound in cloth, \$10.50; in leather, \$12 (currency). Forwarded by mail for 50c. extra, by

DEWEY & CO.

First Street, bet. Howard and Folsom, SAN FRANCISCO
Machinery and Castings of all kinds.

Williams' Swimming Air Machine.

IT CAN BE PLACED AT ANY REQUIRED DEPTH IN A MINE, AND AT THE SAME TIME RECEIVE ITS SUPPLY OF FRESH AIR FROM THE SURFACE.

The cut represents a model of Williams' Swimming Air Machine for Ventilating Mines and Deep Shafts, etc. NO GREASE OR OIL IS USED, thus preserving the air in its pure State.

The Smallest Machine, with a 6-foot stroke, will deliver 3,732,480 cubic inches of cool condensed air in one minute.

In consequence of the swimming of the machine in water, a small amount of power will work it. The inventor is a practical Mining Engineer, and understands the injury to health and strength of miners resulting from hot and impure air, as well as the GREAT ECONOMY of thorough ventilation in mines.

A working model can be seen at No. 13 Drumm street. Mines ventilated, inspected and reported on the most reasonable terms by the undersigned.

Rights to use this machine will be sold on reasonable terms. Address,

WILLIAM WILLIAMS,

P. O. Box 520, San Francisco.

Caveat filed 17th day of January, 1874.

THE MACHINE IS DOUBLE-ACTING, THEREBY FURNISHING A STEADY, UNIFORM CURRENT OF AIR—PUMPED, MOISTENED AND COOLED BY CONTACT WITH WATER SURFACE.

Machinery.

N. Seibert's Eureka Lubricators.

THE HIGHEST PREMIUM

Awarded by the Mechanics' Institute Fair, San Francisco, and State Fair, Sacramento, 1871.

These Lubricators are acknowledged by all engineers to be superior to any they have ever used; feed constantly by pressure of condensed water, supplied by pipe A, regulated under the oil by valve J, and forced out through check valve and pipe B into the steam pipe C; it then becomes greasy steam, passes to all the valves and cylinder at every stroke of the engine; glass tube I indicates amount used per hour. Packing on rods and stems lasts longer, and the rings on the piston will not corrode. One pint of oil will last from three to six days, according to speed and size of engine; I, sliding gauge; K, valve to shut off when engine stops; H, F, valves to shut off in case of frost; steam does not enter the cup; it is always cool; warranted to give satisfaction. Patented February 14, 1871. Manufactured by California Brass Works, 126 First street, S. F. 24v231f

EAGLE IMPROVED CHLORINIZING AND DESULPHURIZING FURNACE.

(Patented July, 1873.)

MILLMEN.

Boss' Quicksilver Pump saves labor and waste of metal. Address, M. P. BOSS, Bullionville, Nev. 15v7-5m

CAST STEEL SHOE AND DIE COMPANY,

OFFICE—Room 28, Hayward's Building, 419 California St., S. F.
Patented CAST STEEL SHOES & DIES for Quartz Mills.

Price, 20 cents per Pound.

An improvement greatly needed—being Stronger, more Durable and Economical than Cast Iron; as the Dies, when worn down, can be welded to the Shoes as easily as bar steel; never break, keep their full striking surface. Battery of five shoes crushes one-ton more ore in 24 hours than Cast Iron Shoes, will wear as long as four sets of Cast Iron Shoes, and can be worn down to 1/8 inch in thickness. The stubs can be welded into Picks, Hammers, etc.

—ALSO—
Cast-Steel Tappets, Cams, Hammers, Gearing and Castings

OF ALL KINDS, A SPECIALTY.

It takes forty days to fill orders.

THE

AMERICAN TURBINE WATER WHEEL.

Recently improved and submitted to thorough scientific tests by James Emerson, showing the following useful effect of the power of the water utilized, being

THE HIGHEST RESULTS EVER KNOWN.

Percentage of part gate, $\frac{1}{2}$ 50.08; $\frac{3}{4}$ 69.64; $\frac{5}{8}$ 78.73; $\frac{1}{4}$ 82.53; $\frac{1}{2}$ 82.90. Percentage of whole gate, 83.14.

Mr. Emerson says: "These are the best average results ever given by any Turbine Wheel in my experience."

A splendidly illustrated descriptive catalogue, or any further information desired, furnished on application to

TREADWELL & CO.,

SAN FRANCISCO, CAL.

Sole Agents for the Pacific States and Territories.

ap25-4f

TO HYDRAULIC MINERS.

I warn Hydraulic Miners not to be misled by the advertisement of Mr. F. H. Fisher. Said Fisher has been beaten in every suit to which he has been a party (respecting Patent Rights on Hydraulic Machines), whether as plaintiff or defendant.

His patrons have already paid over Five Thousand Dollars for license to use machines purchased of the self styled

"Only Reliable Party in the Business Who Protects His Customers."

Fisher's Machine is worthless unless the discharge pipe is furnished with appliances, the patent for which is owned by Messrs. CRAIG, and which Fisher is enjoined from making.

The Machine itself is also an infringement on another patent owned by the same parties.

All persons infringing on either of these patents WILL BE PROMPTLY PROSECUTED.

I am sole LICENSEE to sell Machines manufactured under CRAIG's, Rice's, Macey's and Hoskin's patents.

I Guarantee Full Indemnity to all my Customers.

Machines of all sizes always on hand.

If you want a Machine that will give satisfaction, and do not want to pay for it twice over, buy an improved LITTLE GIANT.

For further particulars apply to

STEAM ENGINES AND BOILERS

Of all sizes—from 2 to 60-Horse power. Also, Quartz Mills, Mining Pumps, Hoisting Machinery, Shafting, Iron Tanks, etc. For sale at the lowest prices by

10v27f J. HENDY, No. 32 Fremont Street.

CROCKER'S PATENT

TRIP HAMMER QUARTZ BATTERY.

This machine, complete, weighs 1,500 lbs. Has an iron frame, five steel arms with stamps weighing 17 lbs. each, which strike 20 blows per minute, in a mortar provided with screens on both sides, and crushes 750 lbs. per hour, requiring one-horse power to drive it. Has been thoroughly tested, and is guaranteed to give good satisfaction. PRICE, \$700.

G. D. CROCKER,

Quartz Crushing & Ore Sampling

MILLS.

Nos. 413 & 415 Mission st., bet. First & Fremont, S. F.

Ours is the OLDEST, LARGEST and MOST EXTENSIVELY KNOWN establishment of this kind on the Coast.

Our mills are under the direct supervision of one of the most experienced Samplers and Millmen in the country, and we purpose carrying on the business upon a scale commensurate with the wants of the mining public.

We have the best facilities for Crushing, Sampling and Pulverizing all classes of Gold, Silver, Copper and Lead Ores and other minerals.

We also crush and pulverize all kinds of Marble, Fire-Clay, Bricks, Coke, Cement, etc., upon the shortest notice, for which we have special mills.

Reliable information furnished to miners and ore dealers concerning shipments, freights, prices, etc.

Prompt execution of all orders. Faithful attention to business entrusted to us.

Abundant storage room without extra charge.

ja31-4f "JIM" WHITLATCH, Sup't.

Important to Miners and Mill Men.

Silver-Plated Copper Amalgamating Plates, for Saving Gold.

Of all sizes and in any quantity, furnished to order. Full instructions sent for operating. Particular attention given to plating goods for Builders, Plumbers, etc. Hotel and Restaurant work replated.

Richardson & Co., Copper Ore Wharves, SWANSEA.

RICHARDSON & CO. have been for thirty years established in Swansea as Agents for the preparation, Sampling, Assaying and sale of Copper, Silver, Gold, Lead, Zinc, and all other Ores and Metals, for which they have extensive Warehouses and Wharves under cover, 1,000 feet of Quay Frontage with the Floating Dock, and the most complete Machinery and Appliances. They are also prepared to make advances against Ores in anticipation of realization, and to guarantee all payments when required.

2v24-4y

Varney's Patent Amalgamator.

These Machines Stand Unrivaled.

For rapidly pulverizing and amalgamating ores, they have no equal. No effort has been, or will be spared to have them constructed in the most perfect manner and of the great number now in operation, not one has ever required repairs. The constant and increasing demand for them is sufficient evidence of their merits.

They are constructed so as to apply steam directly into the pulp, or with steam bottoms, as desired.

This Amalgamator Operates as Follows.

The pan being filled, the motion of the muller forces the pulp to the center, where it is drawn down through the aperture and between the grinding surfaces. Thence it is thrown to the periphery into the quicksilver. The curved plates again draw it to the center, where it passes down, and to the circumference as before. Thus it is constantly passing a regular flow between the grinding surfaces and into the quicksilver, until the ore is reduced to an impalpable powder, and the metal amalgamated.

Settlers made on the same principle excel all others. They bring the pulp so constantly and perfectly in contact with quicksilver, that the particles are rapidly and completely absorbed.

Mill-men are invited to examine these pans and settlers for themselves, at the office, 229 Fremont Street, San Francisco.

Morris' Settler and Amalgamator.

PATENTED MARCH 25, 1873.

An important improvement in milling. Cheap, light, efficient and durable. Gains Quicksilver on working tailings. Is discharged from the surface in the center instead of the side, by means of a Syphon which extends to near the center of the Settler. Heaviest casting weighs only 135 pounds. The sides and bottom of the Settler are made of wood, as also Mullers, placed vertically—the friction of which brightens the quicksilver. One of these machines is in daily operation at No. 616 Merchant street, (basement), San Francisco. Parties desiring information as to rights of use, purchase, etc., can address,

At the lowest Market Prices.

THE ONE-PLUNGER JIG,
Delivered on R. R. Car at Denver, Col.,
or St. Louis, Mo.,
Separates in one and the same operation—1. galena
and sulphide of silver; 2. pyrites or blende; 3. tailings,
containing no valuable parts; or, 1. gold; 2. pyrites; 3.
tailings (quartz, etc.) containing no valuable parts; or,
1. copper; 2. tailings, containing no valuable parts.
The One-Plunger Jig can be combined with existing
stamp-mills with highly important advantages, as after
amalgamation it will recover completely all fine metal
and all base ores and all mercury out of tailings. It
concentrates all fine metal ores to such cleanliness that
low grade ores can be shipped, after concentration, as
first-class ores. Its feed and discharge are automatic.
Its construction offers better guarantee against loss and
repairs than any other apparatus in use. For particulars,
apply to the inventor,

MINING AND SCIENTIFIC PRESS

An Illustrated Journal of Mining, Popular Science and Progressive Industry.

BY DEWEY & CO.,
Patent Solicitors.

SAN FRANCISCO, SATURDAY, MAY 9, 1874.

VOLUME XXVIII
Number 19.

Society of Engineers of California.

The Society of California Engineers held its first ordinary meeting on Tuesday evening, at the Third District Court Room, Mechanics' Institute. Cards of invitation having been issued by the members, the attendance was composed principally of the proprietors and experimenters of the various foundries and machine shops in the city. The President, Mr. G. F. Allardt, addressed the Society briefly in relation to the field for research open to it, and its prospects for the future. He enumerated the different subjects of local interest which it would be well for the members to touch upon in their investigations, and took occasion to suggest that the Society should be careful in selecting new members, choosing only those who were worthy of being admitted, as experts in some special branch.

Mr. J. Spiers, M. E., of McAffee & Spier's Boiler Works, read a highly interesting paper on the subject of "Boiler Pressure." Mr. Spiers is a practical boiler maker, and his views were listened to attentively by those present. His paper was quite exhaustive, and was filed for future publication. There was some little discussion on the conclusion of the reading of the paper, which was engaged in by Messrs. Dickie, Hanscom and Spiers.

Col. W. J. Lewis, C. E., then read a paper "On the Calculation of Earthwork," illustrating his remarks with wooden models of the various forms of which he spoke. His paper was rather abstruse, and as frequent reference was made to letters and figures on the models which could not be seen by the audience, it was difficult to follow him in his line of argument. A blackboard will, however, be furnished by the next meeting, when such subjects can be better explained by means of figures.

The following papers are announced as being in preparation for the society: "On Compound Engines," by Mr. G. W. Dickie, mechanical engineer, of the Risdon Iron Works; "On Quartz Mining Machinery," by Irving M. Scott, of the Union Iron works, mechanical engineer; "On the Mechanical Condensation of Vapors," by James R. Smedberg, consulting engineer of the San Francisco Gas Light Co. "On Sea Diving," by Mr. C. H. Longee, submarine explorer.

The society has made a good start, and is composed of the right sort of men to undertake and carry on such an organization. The present members are: G. F. Allardt, civil engineer; G. W. Dickie, Risdon Iron Works, naval engineer; Melville Atwood, mining engineer; C. H. Longee, submarine explorer; A. V. Ojeda, engineer of steam marine; Samuel H. Wheeler, mechanical engineer; James R. Smedberg, gas engineer; Irving M. Scott, Union Iron Works; W. A. Goodyear, mining engineer, late of the geological survey; Joseph Moore, Risdon Iron Works, mechanical engineer; William J. Lewis, civil engineer; A. C. Dithmar, mechanical engineer; W. A. Phillips, engineer of steam marine; W. W. Hanscom, Etna Iron Works; James Spiers, mechanical engineer; J. Bermingham, mechanical engineer; A. S. Hellidie, President Mechanics' Institute; William R. Eckart, Marysville Foundry; David Stoddard, mechanical engineer.

The officers are as follows: President, Geo. F. Allardt, C. E., Engineer Tide Land Commission; Vice-President, W. W. Hanscom, proprietor Etna Iron Works; Treasurer, Geo. W. Dickie, Risdon Iron Works, Mechanical Engineer; Secretary, Jas. R. Smedberg, Consulting Engineer S. F. Gas Light Co.

Applications for membership should be addressed to James R. Smedberg, Secretary Society of Engineers of California, Gas Office, San Francisco.

SIEBERT VS. GARRATT.—The long contested infringement case of Siebert vs. Garratt, which involved the ownership of an invention claimed by both parties, for an improved lubricator for steam engines, has recently been decided by the Supreme Court of the United States in favor of Siebert. Another suit is now pending in the U. S. Circuit Court in this city, wherein Siebert, as plaintiff, demands that Garratt's patent be declared void. The real question at issue, however, is settled by the decision of the Supreme Court and the new suit is merely a matter of form to clear the illegally issued patent from the records.

Improved Truss for Bridges.

Benjamin F. Graham, of San José, Santa Clara county, California, has recently patented through the Agency connected with this office, an improvement in trusses for bridges. The improvement consists mainly in a novel combination of braces, placed angularly to each other, and transversely to the length of the bridge, by which the inventor is enabled to do away with the outside struts or braces ordinarily employed to steady the trusses from each side. He is also enabled by the use of these rods to straighten and set up any truss which may have become inclined or bent by reason of weakness in the top chord.

The accompanying cuts show the general

GRAHAM'S IMPROVED BRACE FOR TRUSS BRIDGES.

design of the improved truss. A and B represent two perspective views, showing an ordinary truss bridge to which these rods have been applied. C is a transverse section. The rods which unite the upper and lower chord and pass through the sills are set at an angle, so that each pair cross each other, as shown. The

Section Showing Braces.

upper and lower ends may pass vertically through the chords, as the incline will be very slight in a truss of ordinary height, and the rods will easily spring sufficiently to cross each other as desired. When everything is in place, the nuts at top and bottom are screwed up, thus holding the whole truss vertically.

If an old truss has become inclined to one side or the other, the nuts may be loosened, and those upon one side or the other may be screwed up until the truss assumes an upright position, after which all the nuts can be set up tight. In cases where the upper chord proves weak and shows a tendency to buckle, these cross-rods and nuts offer a ready means of straightening it and preserving it in line; and, on new work, all the braces which are usually placed outside the truss and at right angles with the length of the bridge, can be dispensed with, the rods making the whole sufficiently stiff.

There is not a shadow of truth in the story lately published to the effect that 1,000 additional miners were to be set to work in the Belcher mine. They have all the men they can work.

California Earthen and Stone Ware.

The articles coming under this head form a class which it is very essential to have included in our home productions, their bulk and liability to breakage making them objectionable as articles of transportation. This want has been well supplied by the Pacific Pottery, whose advertisement will be found in our columns. The manufactory is at Sacramento, and is the oldest pottery in the State. It has been in the hands of the present company over ten years, and they have certainly achieved marked success. Their ware is not excelled by any of Eastern manufacture, and can be bought at rates quite as low, exclusive of transportation.

We were led to examine the condition of this

Litigation Among the Powder Companies.

The consumption of powder on this coast in mining operations alone is very great, and since bank blasting on the gravel mines has been commenced, this consumption has increased largely. There are several powder companies and agencies on this coast, all of which are doing a remunerative business in supplying this heavy demand, and there is now likely to be trouble among them. The use of nitro-glycerine for blasting and kindred purposes has become very prevalent, but in all cases this article is combined with other substances, to render it less dangerous to handle. Experiments were tried, in order to render it safe, by mixing it with common black powder, chalk, cotton and other substances, but the most effective one tried has been infusorial earth. With most of the other substances, the nitro-glycerine, under certain temperatures and conditions, exudes from the package and again becomes as dangerous as before.

The two companies in this city making compounds of nitro-glycerine and other substances as an explosive, are the Giant Powder company and the California Powder company, the latter of which manufactures what is known as Hercules Powder. Both of these brands of powder are used extensively in the mining regions of this coast. The Giant Powder company of this city and the Atlantic Giant Powder company of New York, own a number of patents for the manufacture of the article, which they obtained from the inventor, Mr. Nobel. These companies now claim that the California Powder company are manufacturing the Hercules Powder in the same manner that Giant Powder is made, and are infringing on the Nobel patents, which the Giant Powder company own.

The invention of Nobel rendered nitro-glycerine a safe compound to handle and the patents are therefore of great value. The two Giant Powder companies have accordingly entered suit against the California Powder company, J. H. Baird, J. B. Haggin, and others of this city. In the east the firm of Bakewell, Christy & Kerr, of Pittsburgh, and S. S. Fisher of New York, late Commissioner of Patents, have been retained, while here Hall McAllister, Alfred Rix, M. A. Wheaton, and J. F. Cowdery have been employed. It is stated that other suits against the consumers of what is known as Hercules Powder will be commenced immediately in each State and Territory this side of the Rocky Mountains, and on the other side a like series of actions is being instituted. The representatives of the California Powder company claim that they are not infringing upon the patents of the Giant Powder company, but are making their powder in a way of their own. Preparations for this suit have been going on for some time, but it is only this week that active measures have been taken. The California Powder company desires to state that they are willing to give a full guarantee to consumers and dealers against all damages from these suits.

RICH ORE.—We recently received a specimen of silver ore from the claims of Dorr, Hunt & Arnold, in Loebner district, 15 miles south of Helena, M. T. In appearance it strongly resembles the mixed colored sulphuret ore of the Comstock. The company own a tunnel right of 3,000 feet on the east side of Red mountain, a mill site and 200 acres of pasture. They claim four veins with galena ores assaying from \$100 to \$500 per ton. Mr. Lewis Dorr, of Yuba City, California, one of the proprietors, intends leaving for the mine this spring.

YAKIMA MINES.—A private letter received in Portland from the Yakima mines states that some very flattering prospects had been obtained at each of the two camps on the main river, as well as those originally discovered at Swauk creek, and the miners are of the opinion that fair wages can be realized throughout the present season.

The Eureka Consolidated Mining Company paid a dividend of \$1 per share this month, amounting to \$50,000, the first paid since last September.

particular market by enquiries from parties wishing to purchase drain-tile. For their information we have obtained from Mr. Owens, the agent in this city, the following list of prices of the articles referred to: Three sizes of drain-tile are made by them—2, 3 and 4 inches—the prices being \$6, \$8 and \$12.50, respectively, per hundred feet.

The variety of articles made by this company is extensive, embracing all that is requisite in this line for housekeeping, draining, manufacturing, gardening and agricultural purposes. The merits of their sewerage pipe have been tested and endorsed by the leading architects and owners of real estate in this city; while their fire brick has been pronounced superior to that imported from England.

This company is now making improved irrigation pipes—their own patent—which will undoubtedly prove an efficient aid in this important department of California farming.

Mr. J. B. Owens has for three years been the San Francisco agent for the Pacific Pottery, and by his business tact and reliability has secured for the establishment an extensive trade and one that is rapidly increasing. To San Franciscans a compliment to Mr. Owens would be superfluous; but we would assure our readers generally, that any business which they may wish to transact with him will be done in a fair, prompt and courteous manner.

MINING DECISION.—Secretary Delano has decided the case of the adverse claimant against the application for a patent to 600 feet on the "Bell-wether" lode, in Colorado Territory. The principal points decided were that sixty days must elapse between the first and last publication of the notice in a newspaper; a publication once a week for nine consecutive weeks was not sufficient. It is decided that notwithstanding the absence of protest, yet, under the Act of 1874, the adverse claimants can show the failure of the applicants to comply with the statute.

CORRESPONDENCE.

Notes of Travel in Colorado Territory.

[By Our Traveling Correspondent.]

EDITORS PRESS:—Colorado Territory, geographically, is the most symmetrically shaped of any of the States or Territories. It runs exactly on the lines of latitude and longitude. It is bounded on the north by Wyoming and Nebraska Territories; on the east by Kansas; on the south by New Mexico, and on the west by Utah Territory; it extends from 37° to 41° north, and from 102° to 109° west. It embraces 100,800 square miles, and contains about 125,000 inhabitants. It is divided into twenty-one counties—Denver, the capital of the Territory is also the county seat of Arapahoe Co., and located near the center of the Territory east and west, and about 100 miles south of the northern boundary; and distant 110 miles from Cheyenne, Wyoming Territory, the point of divergence from the line of the U.P.R.R.

Denver, Colorado,

Contains about 15,000 inhabitants. It is situated at an elevation of 5,317 feet above the level of the sea. The climate is very salubrious, and by many that I conversed with who went there afflicted with asthma this atmosphere is considered a remedy for that disease. It is also very beneficial for pulmonary affections; but to those afflicted with catarrh I would advise to give that country a wide berth, as that climate will certainly aggravate the malady. Denver supports four dailies, and some ten weekly periodicals; of the dailies the *Tribune* and *Times* are evening, and the *News* and *World* are morning publications. There are in the city four banks; and a branch of the U.S. mint is also there. Commercially it has its proportion of mercantile houses, hotels, etc. The principal hotels are the Grand Central, American House, and Inter-ocean. Their charges are from \$2.50 to \$4.00 per day.

The interests of Denver at this writing are neither agricultural nor mining; but being the center for supplies, to the mining districts, and grazing districts of the south and north valleys, its commercial interests are first. However, the real support of Denver at this time is its invalids, every third house being a hotel or boarding house.

Colorado Altitudes.

As your readers may be interested in knowing the altitude of the prominent places in the Territory, I append a short list: Denver is 5,317 feet above sea level; St. Vrain's, 5,256; Greeley, 4,779; Boulder, 5,536; Cheyenne, 6,041; Golden City, 6,226; Colorado City, 6,342; San Luis valley, 6,400; Mt. Vernon, 6,421; Plum Creek, 6,840; Estes Park, 7,528; Divide, 7,554; Idaho, 7,800; Central City, 8,300; Georgetown, 8,452; Twin Lakes, 9,442; Pike's Peak, 14,216; Long's Peak, 14,056; Mount Lincoln, 14,190; Grey's Peak, 14,245; Colorado Springs, 5,975.

How to Reach Colorado from the East.

Tourists can reach Colorado from Boston, New York, Baltimore or Philadelphia, by way of Chicago or St. Louis to Kansas City. Thence take the Kansas Pacific Railway to Denver; distance from Kansas City, 639 miles. At Denver, the tourist connects with the Denver and Rio Grande Railway for Colorado Springs, 76 miles south, passing along some of the noblest mountain scenery in the north, along Plum creek and the Monument valley to Colorado Springs, at the base of Pike's Peak. From Colorado Springs to Pueblo the distance is 43 miles, reached by the Denver and Rio Grande Railway. From Pueblo, stages run south daily, connecting with all important points in Southern Colorado, Old and New Mexico. From Colorado Springs to Cañon City, 86 miles. From this point tourists can visit the famous cañon of the Arkansas, the Iron mountain, Salt Springs, Twin Lakes, Mountain valley, San Luis valley, and other points of interest. At Colorado Springs, 76 miles south of Denver, tourists can visit the famous Cheyenne cañon, which exceeds in grandeur and magnificence both the Weber and the Echo cañon, having a waterfall estimated at 300 feet.

Railroads of Colorado.

The Kansas Pacific railway company, of which E. S. Bowen is general superintendent at Kansas City, and B. W. Fisher is assistant superintendent at Denver, Colorado, own 639 miles of railway between Kansas City and Denver, and are operating the Denver Pacific railroad, with all its branches, under lease (for 99 years), aggregating some 160 miles more. The Denver Pacific railway is located between Cheyenne, Wyoming Territory, and Boulder City and Denver.

The Denver and Rio Grande railroad runs south from Denver to the Cañon City coal mines, distant 155 miles, with as much more projected railway. This company own, and are at the present time working, one of the finest coal mines in the Territory, situated at Cañon City.

The Colorado Central railroad company, of which H. M. Teller is President; Oliver Ames, Vice-President, and P. J. Nichols, Superintendent, are operating the following lines of railway, with distances and officers as follows:

Denver branch, 17 miles; Golden and Julesburg, completed to Longmont—42 miles.

Golden to Black Hawk, 20½ miles. Golden to Floyd Hill, 17½ miles. Total—97½ miles. Golden and Kalston railroad is just starting, and is seven miles long.

Golden and South Platte railroad is nearly finished and is 20 miles long.

This officers of the Golden City and South Platte railroad are C. C. Welch, President, E. D. Bertrand, Secretary and Engineer.

Golden and Kalston railroad—President, E. D. Bertrand; Secretary and Treasurer, L. J. Smith.

Coal Mines at Golden City.

There is now quite an extensive coal mine being opened by the Golden Gats Mineral & Land Compny. There are two veins, making eleven feet of solid coal in all; depth of shaft, 140 feet; course of vein, north 48 west, then North; quality of coal, excellent; free from sulphur. It is used for locomotives, stoves, smelting works and blacksmithing, (ore vein); amount raised per day, seventy-five tons; price of coal at shaft, \$4.50 per ton. Three more shafts are preparing to raise 200 tons per day.

The St. Vrain's Coal Mine

Is on the Julesburg railroad, twenty-five miles from Denver; twelve feet horizontal vein. The shaft is sixty-two feet deep. Coal about the same quality as Cañon City coal; company incorporated in Denver; capital stock, \$200,000.

Value of Colorado Ores.

The following information concerning average assays of different classes of ores of Gilpin county, was kindly furnished me by J. Alden Smith, Territorial Geologist, of Central City, Colorado: Average yield of 370 assays of stamp rock, from Gilpin county ores—gold, \$18.76; silver, \$15.34—coin value per ton of 2,000 pounds. Total, \$34.10. Average yield of 100 assays of smelting ore, from same locality—gold, \$85.90; silver, \$38.22. Total, \$124.62, per ton of 2,000 pounds. Average result of 100 assays of stamp mill tailings—gold, \$20.74; silver, \$5.50. Total, \$26.25, per ton of 2,000 pounds. Average result of 50 copper assays, from the same mines, 12.55 per cent. Average result of 125 assays from Gregory lode—gold, \$43.82; silver, \$13.42. Average result of 25 assays from Bohalt lode, gold, \$66.32; silver, \$9.85. Average result of 50 assays from Kansas lode, gold, \$80.89; silver, \$15.20. Average result of 50 assays from Burroughs lode, gold, \$50.12; silver, \$9.70. Average result of 50 assays from Illinois lode, gold, \$40.60; silver, \$20.92. Average result of 20 assays from Prize lode, gold, \$50.64; silver, \$16.42. Average result of 20 assays from Missouri lode, gold, \$50.12; silver, \$11.01. Average result of 150 assays from Guenell lode, gold, \$40.31; silver, \$10.26.

The Consolidated Gregory

Is a mining property owned by T. J. Richman Esq., and at present being worked under lease by H. Haniugton. This property is located on the southeast, and in the vicinity of Central City, Colorado Territory. The lode or ore body runs southwest by northeast, and like nearly all others in this district, is a regular contact vein, having distinct walls of a micaceous granite on both sides; in some places it is pure granite. This mine has been lying idle for the past four years, until in October last (1873), when a combination of the Black Hawk, Briggs and this mine started up together to rid this lode of water, (these three mines being on the same vein).

Hoisting Works, Shafts, etc.

Their hoisting works are run by a steam engine of 50 horse-power, with hoisting apparatus, pumps, etc., complete in every particular. Their main shaft is 450 feet deep, with a double compartment. They are, however, working this mine at a depth of 600 feet through the Black Hawk shaft. The ore body in this mine runs from 3 to 30 feet in width, and averages about 6 feet thick. Of the ore extracted about 90 per cent. is free milling, that averages some \$15 per ton in gold; the other 10 per cent. is smelting ore and produces about \$100 per ton. At the present writing, they are working 50 men, but will soon put on 100 men. They are extracting only about 20 tons of ore daily—using over half of their working force doing dead work, opening up drifts, etc. They own a 50-stamp mill, located in Black Hawk within one mile of their mine, but not at present working; they intend very shortly to start that up. The first mine struck in this camp was the Gregory.

The Buell Mine

Was formerly known as the Leavitt mine, and consists of the following locations: the Leavitt, Vasa and Kip, on which U. S. patents have been granted. It is owned and superintended personally by Bela S. Buell, Esq. This mine is being developed through one principal shaft, which is down 350 feet vertically, striking the vein or ore body at the depth of 300 feet. There are four othershafts on this mine, varying from 230 to 265 feet deep. From the main shaft some four principal levels have been run upon the vein in opposite directions, aggregating some 1,500 feet, and other levels and drifts in this and other drifts amounting to some 2,000 more. The ore body in this mine runs northeast and southwest, and in character very much resembles the Gregory.

The Extent of this Mine,

Over which Mr. Buell holds U. S. patents, is 2,400 feet; the main ore body of this district, of which this is a part, is traceable and has been prospected for over two miles in extent. There are some fifty men regularly employed at this mine, and are extracting some fifty tons

of milling ore daily, that averages about \$10 per ton; the average for the year 1873 was \$11.23 per ton; and varied from \$5 to \$15 per ton. By the above it will be seen that the ore of this mine is of a low grade, yet the mine is one of the best paying in this district. The vein matter in this mine runs from three to fifteen feet in width. The smelting ore taken from the mins in the past averaged about \$100 per ton, of which they used to extract from five to thirty tons per month. At present all ore extracted is free milling. Mr. Buell is now engaged in erecting

New Hoisting Works and Mill

In connection with each other, to be run, however by separate engines. The mill will have sixty stamps, with all the equipment to make it as complete a mill as any in this Territory. The engine for the mill will be of one hundred horse-power. This mill is expected to be in operation by July 1, this year. It will have a capacity of sixty tons daily. Mr. B. is leasing the New York mill, at Black Hawk, located some 1½ miles below his mine at Central, Colorado. The New York mill has fifty-five stamps and is run by steam during eight or nine months of the year and the other four months by water. This mill's capacity is about fifty tons daily. This mine is not for sale. I will send the continuation of this letter in time for your next issue. L. P. Mc.

Robinson District, Nevada.

EDITORS PRESS:—Thinking you might like to know what we poor, forsaken miners are doing, I thought I would drop you a line, although I am better with the pick and hammer than with the pen. We are a slow moving people, but then we have an abiding faith in the future of this camp. Our great drawback is the

Lack of Capital,

And the intelligent application and use of it, to develop the vast resources of this really rich (in mineral) district. What we really want is a good company to take hold and build smelting works, and buy the ore on the dumps, (provided they do not want to purchase the mines,) paying the owners cash in hand. There would be no trouble in getting any amount of ore which would pay the smelters a large profit. There has been too much trouble already with superintendents that cared nothing about the interests of their employers, or at least the interest of the stockholders.

There are but three companies doing anything at present, the Watson, Ward Ellis and Hayes.

The Watson Co.,

Under the management of D. T. Elmore, superintendent, are working about twelve men at their mine, the North Star, (located at Hercules Gap). I am informed by Mr. Elmore that the mine is looking exceedingly well, and that they are taking out some rich ore. The mill of the company was to have started up on the company's ore on the 20th, but for some cause did not, (owing, I presume, to the reads being unfit for hauling, and a rather small supply of quicksilver). I have no doubt, however, that they will commence by the first of May.

Superintendent B. F. Ward reports that the

Ward Ellis

is looking the best it knows now; they are getting some fine ore, and so far as developed, it bids fair to be the mine of the camp. Lately they have been troubled by water, and the ground is caving. Mr. Ward is having the mine timbered in a thorough manner, and will then go ahead with his developments. Nine men are employed here.

At the Hayes Mine.

Nelson Allan, lately the foreman, is now superintendent. A contract has been let for sinking the main incline seventy-five feet, when a new level will be opened. The mine is opened and partially prospected now to the depth of 185 feet. There is a great deal of low grade ore already developed; ore, which with an honest deal in milling etc., would probably pay the stockholders a profit. A new shop has been built and other improvements made, which makes it look as though business was meant, and faith in the future of the mine was not wanting. Seven men are employed besides the contractors.

Mr. Frank Enas, our enterprising restaurant keeper, has had several men employed on one of his mines all winter. I am happy to state that lately he has struck a body of ore that assays all the way from \$80 to \$200. Several other parties are also prospecting and taking out ore and filing it on the dumps. At some future time I may write you again and let you know how we are prospering. JASPER.

TRANSIT OF VENUS PARTIES.—Two parties will start from San Francisco about the middle of August, to observe the transit of Venus in Japan and China. Professor Davidson, of the Coast Survey, will have charge of the party going to Japan, and Professor Watson, of Ann Harbor University, will take command of the party going to Pekin, China. Professor Titman, of the Coast Survey, will accompany Davidson, and Thomas F. Woodward, also of the Coast Survey, will be detailed for duty, and probably be assigned to Watson's party. Capt. Woodward will not be required to report at Washington, but report to the head of his party, in San Francisco. Professors Davidson and Titman are here daily, studying their future work at the Observatory, in order to be well prepared.

Cinnabar Mining District.

The northeastern corner of Sonoma county has heretofore been chiefly noted as the site of the Geyser springs, which are visited by tourists from all parts of the world. There was in 1860 a mining excitement in that section, which died out from lack of capital to prosecute discoveries, and the belief which prevailed at the time that the Almaden mine was inexhaustible and would supply quicksilver in quantities equal to the demand for all times, at rates cheaper than it could possibly be mined elsewhere. A diminished supply from Almaden, and an increased demand for quicksilver in the past few years, greatly stimulated the search for this metal. About a year ago valuable discoveries were made near the Geysers and Cinnabar district was organized. The main range of the Mayacamas mountains forms the northeastern boundary line between Sonoma and Lake counties. Between Pine and Cobb mountains, links in the main chain, rises Big Sulphur creek, flowing through a deep gorge formed by Cobb mountain and the Hogsback, a spur running nearly parallel with the main range. In the cañon formed by these two mountains, the Geyser springs are located.

Little Sulphur creek rises in Pine mountain, flows west of the Hogsback range around Geyser Peak, and unites with Big Sulphur, isolating, as it were, this immense upheaval, whose highest point, Geyser Peak, is 3,500 feet above the sea level. On the opposite side of Little Sulphur there is a parallel range of almost equal length which, to the westward, breaks into irregular hills terminating finally in the Russian river plain. We have now Cobb mountain in the main range for a background, a parallel range known as the Hogsback on Geyser mountain, and still another parallel range of almost equal altitude—the trend of each being southeast and northwest. Little Sulphur creek flows through Pine Flat, which is situated between the two ranges last named. As the mountains approach each other the valley is pinched out and the creek, leaving the flat, flows through a steep and precipitous cañon.

The main quicksilver lode of Cinnabar district is supposed to come through Pine mountain into the Hogsback or Geyser range near Pine Flat. The ledge runs along this range in the direction of Geyser Peak, near which it crosses the ridge, running from thence in the direction of Cloverdale. It is said that the outcrop has been traced until it terminates with the coast at a point in Mendocino county. Commencing at Pine mountain, we have on each side mines of great promise, the Georgia, Occidental and its extensions on the west side, and those of the English company, including five locations on the eastern side. Between Pine mountain and Pine Flat, a distance of four miles, there are a number of other promising mines.

Near Pine Flat and in the central range above described the outcrop of the ledge is hold and prominent. We have in this mountain, on one side, the Sonoma and its two extensions, the Rattlesnake, the Mohawk, and the Missouries, Nos. 1, 2 and 3. On the other side of the ridge, just above the Little Geysers, are the Bell mine and the Flagstaff. To those who have a general knowledge of the country the above description will give an idea of the direction of the ledge and location of the new mines. The Great Western, in Lake county, near St. Helena, is supposed to be upon the same ledge, and also the Pope Valley mine, in Napa. The Healdsburg and Pine Flat road will wind up the slopes of the most westerly of the parallel ridges we have described, entering Pine Flat at its head, which is near the point where the parallel ridges leave the main range. For this reason the mines are all easy of access from the town of Pine Flat, which it now seems is destined to become a place of much importance.—*Sonoma Democrat.*

SACRAMENTO SMELTING WORKS.—Julius Wetzel, Samuel Poorman and G. M. Gerrish, Directors and Superintendent of the Sacramento Smelting works, will leave for Utah this afternoon to buy ore for the works, and make arrangements for procuring a continuous supply. The building is now all finished. One of the furnaces is completed, and the other will be ready for work this week. These are cupola furnaces, and combine all the modern improvements of volatilizing chambers to oxidize all that comes over the top of the furnaces. There is a Stuyvesant blower put up, which came from Boston, and is the largest on the Pacific coast. The engine, manufactured by Horace Adams, is 40-horse power, full. The capacity of the works is 40 tons a day—two furnaces, but the building was erected with a view to erect additional furnaces when necessary. Water jackets and water lining are put around the furnaces, and they are of the most approved style. A. Henley, who contracted to do the brick work, has done a good job, and so also have the other contractors. The fire-brick, fire-sand and fire-clay used came from Salt Lake. The fire-brick used was made near Sacramento, and is known as Addington's brick. It is said to be of superior quality. The probability is that the fires will be started by the 10th of May, and the works will be run continuously after that. The machinery is all new, of the latest and most approved pattern, and there is little doubt but that there will be good work done.—*Sacramento Union, April 30th.*

The annual product of sulphur from the Sicilian mines is nearly seven million hundredweight, while that from all the rest of the world is only about 150,000 hundredweight.

SCIENTIFIC PROGRESS.

Photographic Engraving.

The subjects suitable for printing blocks, of the kind now to be described, are those known as line and dot subjects, that is, pen and ink sketches, line drawings, engravings, and such like, to the exclusion of objects in pure graduated tint, like a silver print from a negative of a natural subject having graduation of tint.

A plate of glass is coated with a solution of beeswax in ether, the relative proportions of the two being about half an ounce of wax to ten of ether. This leaves a very thin coating of wax upon the plate, which is still further attenuated by rubbing with a cloth. The object of this waxing is to prevent a too close adhesion of the gelatin coating, to be next applied.

To prepare the sensitive surface, gelatin is steeped in water for half an hour or upwards until it has become swollen from the absorption of water; most of the superfluous or unabsorbed water is now poured off, and the vessel containing the gelatin is placed in hot water, or otherwise subjected to heat, by which the gelatin immediately becomes liquefied. To this is added sufficient of a saturated solution of bichromate of potash to render it of an orange color, yet not sufficient to cause the salt to crystallize out and show it upon the surface of a glass plate, coated with the mixture. The film is dried and then removed from the glass, which is permitted to be done by the agency of the wax substratum. It is now ready for exposure.

Suppose now, that a reproduction of an engraving or piece of ordinary print or sheet of music be the subject that is to be produced; a transparency—not a negative of this subject—must have been obtained and superimposed upon the side of the gelatin pellicle next to the glass plate. After exposure to light for a quarter of an hour—more or less, according to the light and quality of the negative—this gelatin film is pressed into contact with any handy flat surface, such as glass or metal, care being taken that the surface that was next the negative be placed outside. It is now sponged copiously with, or immersed in cold water, by which a considerable amount of relief is obtained, the parts corresponding with the block of the original print or drawing being seen standing in high relief, while the whites are sunk. This, it will be seen, supplies the conditions for a surface block to print in connection with type, all that is now wanted being the conversion of the soft gelatin into hard, unyielding metal.

The gelatin relief or mold obtained in the manner described is, first of all, made surface-dry by means of bibulous paper, and is then lightly dusted over with finely pulverized plumbago or bronze powder. A cast from this surface is then taken by means of molten beeswax, which, when cold, readily parts company with the gelatin relief, owing to the intervening sprinkling of plumbago or bronze. This wax cast is then sent to the electrotypist, who, in a few years afterwards, will deliver a metallic cast, mounted upon wood and ready for working in the printing press. This process originated with Mr. Thomas West, of London.

—British Journal of Photography.

The Coming Transit of Venus.

At the Greenwich Observatory a very ingenious little apparatus has been constructed in order to train the assistants in photographing the transit of Venus. It consists of a mirror placed upon a heliostat that represents the sun, so that whenever there is sunshine the model is as bright and luminous as the orb of day itself. Traveling in front of this light is a strip of glass carrying a tiny disk of platinum to represent Venus, and this is made to move by clockwork along the same path that the planet will take across the sun's disk. Viewed by a telescope from below the sun, the planet and the rate of motion are exactly the same as the original will appear to our observers in December, 1874. It is furnished with a tell-tale attachment that points out mistakes in faulty observations. Photo-astronomers will practice on this model until thoroughly conversant with the nature of the work to be performed.

Mr. Janssen's method for photographing the transit of Venus is as follows: The photographic plate is in the form of a disk, fixed upon a plate which rotates upon an axis parallel to that of the telescope. Before it is placed another disk, forming a screen in which is a small aperture, in order to limit the photographic action to the edge of the sun. The plate which carries the sensitive disk has 180 teeth, and is placed in communication with an escapement apparatus actuated by an electric current. At each record the pendulum of a clock interrupts the current and the plate turns one tooth, so that at each second a fresh portion of the plate is exposed. Thus in as many seconds 180 images of the sun and the planet can be obtained. When the series relating to the first contact is obtained, the plate is withdrawn and another substituted, which gives the second contact, and so on for the four.

—College Courant.

NITROUS OXIDE.—Jolyet and Blanche state that experiments made on pigeons and dogs show that nitrous oxide is not a true anæsthetic, but that it produces insensibility by asphyxia.

What is Steel?

Under this head Mr. Elbridge Wheeler, of Philadelphia, claims to have solved this problem and we give place to his remarks on this subject: There has of late been considerable discussion upon the subject of iron and steel, and we think, according to the best information that can be obtained, no one ever had better opportunity for testing the relative properties of steel and iron than Sir William Armstrong, with the kingdom of Great Britain to back him.

Sir William says: "It is impossible that I can hold any other opinion than that the vibratory action attending accessive concussion is more dangerous to steel than to iron;" and we think that years of experience in the manipulation of iron and steel fully attest the correctness of his opinion.

What we desire to impress upon the public mind is the importance of the two metals combined for such purposes, and in such proportions as are best adapted for the uses they may be intended; and further, to give a few facts in the working of steel by our process, which we think of great utility, and which, so far as we know, has never been accomplished by any other process.

We contend that steel cannot be made to answer the purposes of steel and iron at one and the same time; that is, in fact it must be either steel or iron—hence high grades and low grades of steel, as they are termed, and the lower grades but little if any better than the best grades of iron.

It has been said that no one could tell where iron leaves off and steel begins, but we think steel commences where iron presents carbon, and steel is no longer steel when it has lost its carbon, for it is carbon that makes steel.

At a recent convention of the American Railway Master Mechanics' Association, held at Baltimore, it was contended that steel axles did not wear as long as iron. The reason is obvious. No engineer would think of using a car axle made of steel proper—that is, of steel high in carbon, which would give the necessary wearing property—but must have steel that will stand the axle test of iron; consequently it is but iron, or a very low grade of steel, which for wearing purposes is no better than iron.

A similar difficulty arises in the manufacture of railroad rails. Steel that is best adapted to wearing purposes is liable to sudden fracture, and would not be considered safe "under accessive concussive strain," quoting a well known authority; therefore, the Bessemer steel rail has but the slightest amount of carbon, or barely enough to distinguish it from iron.

We claim that we have a process that will make safe and reliable high grades of steel under any and all circumstances, giving longer life to rails and axles, and safe and reliable as the best iron, by combining iron and steel together.

It is a well known fact that ingot steel is more or less open, porous, or spongy, and that no amount of blooming or hammering unites or welds the particles, from the fact that a welding cannot be taken upon the ingot after leaving the mould; by our process we can safely bring an ingot to a welding heat, and finish it into a bar at the same heat without in the least detracting from the quality of steel.

THE ACTIVE PRINCIPLE OF YEAST.—It is stated in a foreign scientific journal that M. Hoppe-Zeyler has recently made a communication on the separation of the active or active matter in yeast from the yeast itself. This matter is procured in the form of a white powder, soluble in water, and which may be preserved intact in a dry state or in pure alcohol. Beer yeast in an active or living condition retains this substance, and will not yield it up to water; but when the yeast is killed by means of ether, the yeast readily abandons the ferment to the water and the active substance or principle is obtained by evaporation. The aqueous solution of this ferment, or active principle, acts in the same manner as the yeast itself, and rapidly transforms sugar into alcohol.

PREPARING AMMONIA SALTS.—Bobrownicki, of Paris, proposes to prepare ammonia salts from the ammonia liquor of gas works by acidifying and then treating it with fluoride of silicon, chloride of silicon, hydrofluoro-silicic acid, or an alkaline silicate. The silicon compounds carry down the suspended bodies, and those in solution, and hold them in a solid or half-solid form. Bobrownicki calls the precipitate a silicoid. It furnishes the crude material for preparing ammonia salts in the usual manner.

A NEW METHOD, by Mr. Wilson, for lighting street gas lamps is as follows: The lamp has two burners; one, very small, burns all the time. When the gas pressure is raised, a small gas holder, on the top of the column, is elevated, affording a passage for the gas to the larger of the two tips, which is lighted by the small jet. Thus all the street lamps in the district may be lit automatically.

WITH respect to unalloyed copper, M. Riche finds that its density, when alternately submitted to mechanical treatment, tempering and annealing, is variously affected according as the metal is protected from or exposed to access of air. In the former case the mechanical action increases, and in the latter case diminishes the density. The introduction of a small proportion of iron gives considerable tenacity and hardness to copper.

MECHANICAL PROGRESS.

Puddle Walls.

A correspondent writes for information relative to making a fish pond in a valley by constructing a dam across from one side to the other. The essential idea in a dam is its capacity for holding water. To this end it must be of sufficient substance, so that its weight shall secure it from being overturned or pushed away by the pressure of the water. It must also be constructed so as to be watertight.

To secure this last requirement the most effective method is to include within the dam a puddle wall. The correct method of puddling, so simple in itself, is not always practiced. The popular ideas in regard to this important part of the work are erroneous. By many persons it is supposed that the best material for the purpose is clay. This is an error. Pure clay is, in some respects, the worst. Again, it is supposed that the work must be compacted by a rammer. Ramming is not effective in compacting it. There are still other erroneous notions entertained on the subject, but we will perhaps best expose the objectionable methods by simply stating the correct one. If the puddle is to extend across a valley, commence by removing from the surface, where the wall is to stand, all rubbish, brush, grass, roots and other perishable material, as well as all surface soil down to the solid natural gravel or ground. In doing this, excavate a trench equal in width to the thickness of the wall. Make the bottom of the trench level across the bottom of the valley, and extend it into and up each side hill in level benches or steps, so that at all points the wall shall have under it a level surface to stand upon.

Next, the material. This should be a gravelly loam, taken from a bank where alternate layers of gravel and loam, or clay, are found. Screen from it by a rake all stones larger than an egg. Spread it to an even depth of four inches in the lowest trench. Sprinkle water over the whole surface by a hose or buckets until the material is soaking wet, when another layer of dry material four inches deep is to be spread over the first one. A convenient method of regulating the depth is by setting up staked intervals stakes projecting eight inches above the bottom of the trench with notches cut four inches from the top. In placing the first layer, the workman is guided by the notches. The second layer is carefully graded to the top of the stakes. Now place a plank, equal in length to the width of the trench, across it near one end. Standing at one end of this plank with a shovel, hold it upright, the back from you. In this position push the shovel to the bottom of the trench by aid of the foot on top of the blade, and then push the handle horizontally from you with force. Withdrawing the shovel, move along the plank the width of the shovel, and placing its point in a line with the position it before held, again press it to the bottom of the trench and horizontally from you. Continue this operation until you have moved along the entire length of the plank. In doing this, you have formed a wedge-shaped opening across the trench.

In returning along the plank, slice off, in the same manner, about an inch in thickness from the edge of the opening nearest you, pushing it compactly upon the material previously packed. Continue this process, cutting slice after slice, until the edge of the plank is reached. Turning the plank over gives room for more work. Follow this operation until the whole of the material is cut and compacted. In making these cuttings, the water which was put upon the lower layer of four inches, is squeezed up through the whole of the upper layer, and the whole thickness of material is rendered of the consistency of putty. The next morning the puddle will be found sufficiently hard to walk upon freely. Then repeat the entire process of spreading the two separate layers of four inches each, watering the first layer and cutting and compacting as before. By this method, double layer upon double layer is to be laid until the top of the wall is reached. Some parts of the operation may appear unimportant and thus be neglected, but many who have so thought and acted have found to their sorrow, after the completion of the work, the necessity of adhering strictly to what experience has shown, in some of our largest engineering works, to be the true method of making puddle walls.

The thickness of the wall should be in proportion to its height and length. For small ponds, a wall four feet broad at top and gradually widened downwards at a rate of one and a half inches per foot of height on each side, or three inches on both sides, will be of ample strength. The puddle wall must be covered from the air on all sides by the filling and stone work used to form the dam.—Sci. American.

IMPROVEMENTS IN THE MANUFACTURE OF FLOOR CLOTHS.—In these glue or gelatine is first combined with any suitable vegetable or animal oil or mixture of such oils, the combinations being effected by intimately mixing the oil in a solution of the glue or gelatine in about its own weight of water, the solution being maintained at about the temperature of boiling water. The combined glue and oil is then intimately mixed with any suitable powder. The plastic mass formed by combining the ingredients as described is applied or spread by rollers or other means, and whilst in a heated state to a backing of jute cloth or any other suitable woven fabric.

Copper Boilers.

In the production of a good copper boiler quite a number of processes are necessary. Such boilers vary in capacity from thirty-five to eighty gallons. The former are about thirteen inches in diameter and about fifty-eight inches in height, and the latter twenty-eight in diameter and of the same height. Ordinary sheathing copper, weighing about two pounds to the square foot, is generally used. It is not necessary to employ heavier sheathing, as the pressure within the boiler is seldom over sixty pounds to the square inch, unless the water is allowed to become overheated so as to produce steam.

Sheathing measuring four by five feet is used for the smaller boilers, and eight by five feet for those holding eighty gallons. The sheet is first bent into shape by hand and hung upon a rod over a fire and the two edges brazed together; the boiler then possesses the appearance of a cylinder open at both ends. The brazing takes about ten minutes. The seam formed in this operation is, of course, rough, and the next process is to render it smooth by hammering. The latter operation, however, leaves the copper near the seam quite hard, and the boiler is next hung upon a rod and heated over the fire to soften it. The cylinder is then put "in pickle," or to speak more scientifically, it is immersed in a bath of nitric acid and water, contained in a box five feet long by two wide and two feet deep, and lined with tin. The proportions of the pickle vary according to the season. In winter the solution is made stronger than in summer; that is, the proportion of water to acid is less in winter than in summer. The cylinder remains in the solution from one to two hours, according to the season, in winter longer than in summer.

When the boiler is removed from this bath it is washed inside and out with water and rubbed with sand. It is now hung over the fire again, and its interior surface is tinned by rubbing pieces of solder up and down the boiler, assisting the operation with a swab. This operation generally does not take over fifteen minutes. The boiler must now be cleaned with weak nitric acid again, after which it is washed, placed upon a horse, and the exterior carefully swabbed. After this the boiler is laid upon a mandrel, and the seam hammered again, this time with a polished hammer, to make it perfectly smooth and level with the rest of the surface. The boiler is then rolled. The machinery by which this is accomplished is peculiar, and may be thus described: A common railroad rail is laid upon a heavy frame, the upper surface of the rail, however, having been planed off. A carriage rolls along the frame and is so arranged that the weight mainly rests upon a small iron or steel wheel which bears upon the rail. The copper cylinder is passed around and is supported by the rail, and the carriage, which is weighted with 600 lbs., is rolled over it. This presses the seam neatly down and gives a finish to the boiler. The edges of the cylinder are then tinned over preparatory to affixing the heads, as it is necessary to protect every portion exposed to the action of the steam. The heads, which have previously been spun from circles of copper and grooved in whatever style may be thought most ornamental, and afterward tinned, are then soldered on.—Iron Age.

A NEW AND PRACTICAL IMPROVEMENT IN UMBRELLAS.—We have been shown an umbrella which, by its simple and ingenious construction, can in a moment's time, when desired, be folded up and packed in a valise, or carried in the pocket. The ribs are cut in two parts, and secured together by means of a slide, so that when the umbrella is folded one section of the ribs slides along the side of the others, thus reducing the ribs to one half their length. When the ribs are extended and ready for use, they are held in position by an extra set of braces, which serve the double purpose of holding the ribs at their full length, and giving extra strength to the umbrella. The stick is jointed in the center by a link and slide ferrule, and is folded up with the ribs.—Technologist.

A CHANCE FOR INVENTORS.—An exchange says: A common, well built country wagon, weighing about 800 pounds, will carry 3,000 on any fair country road, and without injury pass over obstructions which cause it to fall one, two, or more inches, the paying weight being about 79 per cent. of the whole. The ordinary box car in use upon our railways at the present time weighs about 10 tons; its maximum load is generally about 11 tons, while its average load is about eight tons; the paying weight being from 44 to 52 per cent. of the whole. It does not seem reasonable that the weight of a car constructed to run upon a smooth, even track, without a fall, should be so disproportioned to the load carried. There is here a chance for inventors to devise a light form of freight car, strong enough to carry 11 tons.

WRITING INK is one of the things in which modern science seems to have made very little improvement. A recent analysis of the ink found on a manuscript of the year 910 showed that its composition was similar to that of the ink now in general use. In printing inks, however, modern science has made many improvements, of which every advantage has been taken.—Newspaper Reporter.

BOAT PLUGS.—A new invention consists of a ball-valve so placed in the bottoms of boats or other vessels as to remain open when out of the water, but instantly and automatically to close on being placed in the water.

New Incorporations.

Meetings and Elections.

PROOFER S. M. Co.—May 4.—J. D. Fry, A. K. P. Harmon, James A. Pritchard, W. E. Hale and Charlee E. Elliott. The shaft is down 740 feet, and is being sunk at the rate of 10 to 12 feet per week. A drift has been

KOHLER'S REDUCTION WORKS.—May 2.—President: R. J. Kohler; Vice-President: Abner Sedgley; Secretary: Harrison P. Eayre; Treasurer: Abner Sedgley; General Superintendent: R. J. Kohler; Superintendent of Construction: Abner Sedgley. Trustees: R. J. Kohler, Harrison P. Eayre, Wm. Meeke, Abner Sedgley, Jacob Kohler, Edward Kohler.

Mining Accidents

On the morning of the 2d instant a fearful accident happened in the Yellow Jacket mine, caused by the giraffe parting from the cable in some manner and running down the main incline, a distance of 600 feet, with frightful velocity. In the bottom of the incline were six miners at work—Cornelius McCarthy, Richard Pearce, Samuel Odgers, Thomas Odgers, Charles Bennett and Francis Polkinghorn. McCarthy and Pearce were crushed to death, their bodies lying horribly mangled and almost unrecognizable. Samuel Odgers had the left side of his jaw broken, and was otherwise seriously hurt and injured. Bennett was cut about the shoulders severely. Thomas Odgers had one foot crushed and his back badly hurt. Polkinghorn received a severe cut on the side of the head, and was bruised on other parts of his body. McCarthy, one of the killed, was a native of the county of Cork, Ireland, and married; aged twenty-eight years. He was a leading member of the Gold Hill Miners' Union, and a highly esteemed citizen. Richard Pearce was a native of Cornwall, England, twenty-two years of age, single, and a young man of fine abilities. The Gold Hill News says that how the accident happened seems to be a complete mystery, except that by examination it was shown that the wire cable, where it was riveted to the sheikls which attaches it to the giraffe, had pulled or torn completely out, and that the giraffe also had the usual safety attachment, but which from some unaccountable cause did not operate as it should.

The Coroner's jury returned a verdict exempting any one from blame, but recommending that some measures be taken for the prevention of such accidents.

This *Foothill Tidings* states that a man named Hsammel, underground foreman in the Idaho mines, while engaged in "firing a pass," was struck on the head by a falling rock, which rendered him for the time insensible, fracturing the skull and otherwise injuring him severely. This "firing a pass" is rather dangerous work. A pass, or chute, for the passage of rock from one level to another, becomes choked; it cannot be opened by hand when the obstruction is far up, and resort is had to powder and shell. A cannon is placed at the mouth of the chute, aimed directly at the obstruction and fired, often breaking the wedged pieces of rock and liberating the whole mass at once; but if not, it must be fired again. We explain for the benefit of our non-professional readers who might not know what "firing the pass" meant. This mine in which this accident occurred, the Idaho, employs some 300 men, and, although accidents are not frequent, three happened there last week. George Lord, foreman of engineers, while working at the engines of the old hoisting works was struck in the eye by the rebound of a cold-chisel, inflicting a painful though not dangerous wound. Pat Nevins had his thumb mashed by a drop of the mill battery, while at work adjusting a stamp-head.

At the Empire mine, Grass Valley, a miner, named G. Richard Williams, was caved upon and had his right leg broken.

MINERS complain that the Virginia City labor market is overstocked, and that an unusual large number of skilled miners are out of employment at the present time.

BULLION.—The amount of bullion dispatched last week from Pioche, by Wells, Fargo & Co., is \$65,667.21; and Pritchard's freight line, \$7,239.30; total, \$82,906.51.

Rumors are prevalent of a recent strike of rich diggings in the hills in the vicinity of Reess river.

Mining Stocks.

The mining stock market still continues depressed, and the transactions at the Board show light sales and low prices. The rise predicted for the first of May has failed to put in an appearance. Still the mining prospects continue good. As far as the situation in Washoe is concerned, the *Enterprise* says: The low price of stocks does not at all discourage our mining men; More machinery is now arriving and being set up in this section of the State than at any other period in the history of the country. The ore-producing mines are all looking and yielding unusually well, giving encouragement to all who are delving in this range of the great lode to continue their explorations till they reach productive ground. The richest deposits of ore often lie but a few feet from the most barren rock, therefore good fortune may be near at hand when no promise of it cheers the labors of the miner. At best, the opening up and development of mines is a tedious business, therefore all who have to do with them must exercise the virtue of patience. The many companies prospecting are earnestly and honestly engaged in such work as seems best calculated to make known the value of the ground upon which they are located, and while this is the case, stockholders should be content to await the result of explorations in progress, resting assured that no man would be more rejoiced should valuable developments be made than those who are directing and are immediately connected with the work.

Prominent fluctuations in stocks for this week were as follows: Belcher has run between \$81 and \$87; Best and Belcher, \$21 and \$27.50; Maldonian, \$15 and \$21; California, \$33 and \$40; Cons. Virginia, \$73 and \$85; Crown Point, \$82 and \$86; Exchequer, \$19.75 and \$27; Gould & Curry, \$17 and \$22; Hals & Norcross, \$31.50 and \$41; Kentucky, \$11.50 and \$14;

Ophir, \$12.50 and \$17.25; Overman, \$23.50 and \$45; Savage, \$61 and \$64.50; Seg. Belchar, \$64.50 and \$81; Sierra Nevada, \$15 and \$17; Union Cons., \$10 and \$14; Yellow Jacket, \$64.50 and \$82, Enrska Cons., \$16.75 and \$18; Raymond & Ely, \$22 and \$24.

Prominent declines from highest prices of last week were as follows: Alpha Consolidated, \$2.50; Belcher, \$5; Caledonia, \$3; California, \$4.50; Consolidated Virginia, \$2.50; Crown Point, \$6; Exchsquar, \$8; Gould & Curry, \$2; Hals & Norcross, \$3.75; Kentuck, \$2.25; Ophir, \$4.75; Overman, \$5; Savage, \$2.50; Ssg. Belcher, \$14; Sierra Nevada, \$2; Union Consolidated, \$3; Yellow Jacket, \$2; Golden Chariot, \$2; Raymond & Ely shows an advance of \$2, and Eureka Consolidated an advance of \$1.

The Silver Cord M. Co. propose to increase its capital stock from \$1,200,000 to \$2,400,000, in 24,000 shares of \$100 each.

The call of Philip Falk, President of the Page & Panaca M. Co., Ely district, has been responded to by the stockholders, and many of them have paid up their assessments before the time required by law, in order to place the financial condition of the company on a good footing.

SAN DIEGO MINES.—There are now three steam quartz mills at work in San Felipe cañon, Banner district, San Diego county. The Chariot mine, the "banner mine" of the district, is expected to send down a great deal of bullion this summer. Around Julian City, affairs are not so lively as they were; a large part of the business formerly done there being now done in the cañon below, where the mills are.

THE Richmond Company at Eureka shipped 20,000 pounds of bullion on Monday of last week.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

California.

ALPINE COUNTY.

SILVER CLOUD.—*Chronicle*, April 25: After a suspension of ten years, work was resumed this week on the Silver Cloud mine. It is intended to sink 300 feet.

AMADOR COUNTY.

THE QUICKSILVER MINE.—*Dispatch*, May 2: Reports from the Amador quicksilver mine continue to be more and more flattering, and its richness is satisfactorily proven.

PROSPECTING.—*Ledger*, May 2: The recent discovery of cinnabar in El Dorado county has infused a spirit for prospecting among many of our citizens, and in their researches for quicksilver, many discoveries of metal-bearing rock have been made, some of which may eventually prove of value. We were shown a few days ago an ore, that greatly resembles tin, very heavy, and very rich in whatever metal it may contain. We were likewise shown a specimen of chrome iron, which will evidently assay 70 per cent. A heavy ledge of manganese is known to exist west of us, which assays 50 per cent, and asbestos has been found in several localities in the county—at one place, said to be somewhat abundant.

PLYMOUTH.—Reports from Plymouth are very encouraging. The Phoenix mine is still yielding excellent rock and in any desirable quantity; the mill and mine are kept easily and cheaply supplied with wood, timbers, lagging and other material required in the mine, by floating the same down the canal that affords motive power to drive the mill.

THE ALPINE.—The prospect in the Alpine is very flattering, and as work progresses the mine gives still further evidence of soon proving a valuable and permanent mine. Placer mining is being carried on to a considerable extent in the vicinity of the town, and a number of claims are paying well.

THE DISCOVERY NEAR VOLCANO.—The discovery near the Marklee mine still continues good, and yielding largely. The claim is on Russell hill, a locality in which extraordinary rich deposits have been found. In the recent discovery, the largest nugget yet found weighed 15 ounces, with a large number of others varying from one to three ounces. The claim bids fair to be lasting.

The tunnel now being driven by McKay & Co. in Murphy's ridge is progressing rapidly, with the most flattering prospect of developing as valuable quartz veins as have ever been discovered in the county.

Work is still progressing along the gravel range of hills, along the graded road leading to Ione city, and in many of the claims very flattering prospects have been discovered.

CALAVERAS COUNTY.

MINING ITEMS.—*Citizen*, May 2: At Mokelumne Hill several large hydraulic mines have been opened and hoisting works and a mill are being erected on Lamphear's quartz ledge near town. This mine has been prospected to considerable extent and it is the opinion of mining experts that all needed to make it a paying ledge is capital sufficient to work it. At Mosquito Gulch the San Bruno quartz mine is paying \$60 per ton with plenty of the same quality of ore in sight. The last clean-up netted \$12,000. At West Point the severe winter has retarded mining, but several large mines will be worked this summer, and a number of small pocket ledges which are good for large wages to the owners. Rail Road is taking a rest at present, although considerable prospecting is being done by private individuals. At El Dorado, Rodesino is getting good prospects in his ledge and will soon start the mill. Treat & Wylie have commenced work at Gascon Hill and if their hydraulic pays there is a large extent of country equally good, only needing capital to bring water on it and furnish pipe etc. At the Sheep Ranch, the Ferguson & Wallace mine is steadily holding the even tenor of its golden way, turning out \$90 to the ton.

DONNELLY'S MILL started up last week on rock from Potter & Morse's mine, a short distance down the creek. Wood has better rock than ever before.

The Echo hydraulic claim, 5 miles from Murphy's, is the largest in that section of country. At Douglas Flat mining is as brisk as usual. The deep placer mine here will undoubtedly last many years.

ANGELS is at present dull. Although there are a number of arastras grinding out gold.

EL DORADO COUNTY.

REPUBLICAN.—May 2: The Oregon mill is now engaged in crushing rock from the Rose mine. A run on rock from the Oregon mine will be made soon.

FRESNO COUNTY.

COPPER.—*Expositor*, April 29: The Ne Plus Ultra Copper Mining company will shortly ship between 70 and 80 tons of ore to San Francisco. The ore is being hauled from the mine to the railroad. If the Railroad company would reduce the freight on copper ore to about \$40 per car load from Berendo, it would be the means of starting up four or five copper mines in the vicinity of Buchanan. At the present price of freight none of the mines can be profitably worked.

KERN COUNTY.

MINING DITCH.—*Miner*, May 2: Our enter-

prising mining man, E. R. Burke, has inaugurated another big project, which is the construction of a mill race, that will be ten miles in length, and powerful enough to run the hoisting works and pump at the mine and the eighty-stamp mill. It is a big job, but the mind, which has brought Kernville and the two adjacent towns into note and revived the interest of the Southern mines is equal to the task.

EIGHTY STAMPS.—The ground on which this large mill is to be built, has been graded. Stamps, machinery, etc., are en route. The Big Blue mine with these additional stamps will lower those 2,000 tons of rock, which have been accumulating ahead of the stamps during the past year.

NELLIE DENT.—Over 100 ft. have been sunk on this mine. They are now cross-cutting on the ledge, but have not got through. The mine is a twin sister of the Big Blue ledge.

PROSPECTING still continues on the extension of the Joe Walker.

NEVADA COUNTY.

IDAHO.—*Grass Valley Union*, May 5: Gross yield for the month of April \$63,000. The usual monthly dividend has been declared, payable immediately. It will amount to \$38,750, or \$12.50 per share. A larger dividend could have been declared, but the company is now incurring extra expenses in putting in a new engine, air compressor and the Burleigh drill. Four of these drills will shortly be put to use. They will be driven by compressed air from machinery stationed at the surface. The drills will be set to work in about one month.

EUREKA.—The ground between the fifth and sixth levels continues to pay well. The yield for the month, with ten stamps running, was \$24,000.

MAONTA.—This new mine is giving every encouragement of future richness. A good deal of annoyance is experienced from this surface water yet, but with the discontinuance of the rains this drawback is becoming of less serious moment. In the mine there are two distinct ledges, upon both of which drifts have been run. One crushing has been made the past month of 100 tons which yielded \$19 per ton. There are now over 150 tons of rock on the dump.

COE.—The main shaft of the Coe is down 506 feet. No stopping is being done at present, but all the work is directed to getting the levels opened so that a large body of ground may be available for stopping out.

NEW YORK HILL.—The developments of the past month have been most encouraging. The rock in the lower tunnel has improved greatly in appearance, and some of it will go at least \$100 per ton.

SLATE LEDGE, or better known as Perrin's mine, is working steadily, but not with a large force of men. The incline is now in 625 feet. The stopes are looking well.

EMPIRE.—The general appearance of the mine is good. A great deal of prospecting has been done for several months past in running drifts for further developments, and with encouraging results.

PROSPECT MINE, or West Idaho, on Slate creek, is energetically worked. The tunnel being driven for the ledge is in 300 feet, and the presence of quartz stringers in the heading indicates that the ledge is likely to be struck at any moment. The shaft on the croppings is now down 45 feet.

TOWN TALK gravel mine is running night and day, working a force of from 26 to 30 men. The main tunnel is in 1,500 feet, and other tunnels are being driven to prospect new ground. The month's run has not been up to the average yield, but the prospects for the future are very encouraging, and the extent of ground to be worked is almost unlimited. The mill is driven by water-power, and a hardy-gurdy wheel is used. The power is directly attached to the cam-shaft, which makes a simple and complete arrangement, and altogether the cheapest running mill in the district.

DARTMOUTH has a perpendicular shaft 55 feet deep, from the bottom of which a drift is being run north-west. This drift is now in between 300 to 400 feet. The gravel they get is washed in a sluice, and the cement all goes through the batteries at the mill, which is run by an undershot wheel. We believe this is the only mill that uses this power, at least around here. The Dartmouth is working on rock that in the halcyon days of '52 was discarded as not worth working, but Capt. Miller has successfully shown that this regarded poor ore will pay with modern machinery and knowledge.

OTHER GRAVEL MINES.—The Independent, adjoining Town Talk, is still running the new tunnel, which is in 800 feet. No gravel for washing is being taken out at present.

Excelsior is also running tunnel. Not yet in to gravel.

Consolidated Blue Gravel has been idle all winter. Expects to start up soon.

SOLANO COUNTY.

COAL DISCOVERY.—*Chronicle*, April 25: John Stills, of Green valley, has discovered coal outcroppings on his ranch, and the indications are favorable to the presumption that he has a regular lead.

SONOMA COUNTY.

NEW DISCOVERIES.—Quite an excitement was created during the early part of the week by the announcement of extraordinary discoveries of quicksilver in the vicinity of Mount Jackson, four miles in a northerly direction from Gnerneville. The rumors were vague and the reports highly colored. The new mines are distant about 27 miles from Santa Rosa. We visited and examined the mines and returned the same

day; distance traveled on horse-back not less than 57 miles. We think that there is an excellent prospect for a mine here which would fully justify the expenditure of a sum sufficient to determine its value.

TRINITY COUNTY.

MINERSVILLE.—*Journal*, April 25: From Jacob Bowerman we learn that miners at Minersville are hard at work, and prospects cheering. Minersville is the land of nuggets; the last one picked up was by Mead & Alden, and weighed \$81.

DOWN THE RIVER.—W. T. Malone, from Cox Bar, tells us that miners in that part of the county are well supplied with water and are making good use of it.

TULARE COUNTY.

HO, FOR THE MINES!—*Times*, April 25: The rush to the new mines has already commenced. At the present time many parties are encamped at the foot of the snow line, hoping to be the first to enter the mineral regions on the disappearance of the snow, while many others are now on their way to the mountains. There is no doubt but that thousands will wend their way in that direction during this rapidly approaching mining season.

YOLO COUNTY.

COAL AT BUCKEYE.—*Mail*, April 30: An old "49er" and an "honest miner," has placed upon our table some specimens of bituminous coal which he found on the ranch of S. M. Enos, about seven miles west of the village of Buckeye, Yolo county. These specimens, he says, were taken from the surface of the ground with a pocket knife, and, of course, can only be the color of what may be found by a more thorough investigation. There has been no excavation to ascertain just how deep the vein may be, but the ledge from which these specimens were taken is sufficiently solid to satisfy him that there is coal there, and that it is continuous.

Nevada.

WASHOE DISTRICT.

CONSOLIDATED VIRGINIA.—*Gold Hill News*, April 30: The sump for the shaft is finished 25 feet below the 1,500-foot level. The main south drift, on the 1,400-ft. level, and the north drift from the north winze, have been completed, giving a fine circulation of pure air, which will cool and greatly facilitate work in that portion of the mine. The ore breasts from the 1,000-ft. level down to the 1,400 are looking splendidly throughout, and promise a long and rich yield for the future. The bullion production of this mine will amount to the neat little sum of \$400,000 for the present month.

OPHIR.—The ore developed in both the winzes from cross-cuts Nos. 1 and 2, on the 1,300-ft. level, continue to show quite favorable, the ore giving good assays, with a fair promise of the development of a considerable body. The south drift on the 1,300-ft. level only lacks about 8 feet of connection with the north drift on the same level from the Virginia Consolidated, which, when completed, along with the connection of the winze and up-raise from the 1,465-ft. level, will give a fine and perfect ventilation of the entire mine to that depth.

HALE & NOACROSS.—Sinking the main incline is progressing 20 feet per week. In the west cross-cut, on the 1,900-ft. level, the ledge has been penetrated 80 ft., developing small bunches and streaks of ore, but finding nothing that will pay for extraction.

SERRA NEVADA.—Sinking the main shaft is making good progress. The drain tunnel is finished and connected with the shaft 165 feet below the surface, which will make a great saving in the cost and labor of pumping the water when it may become necessary. Putting in the foundations for the new machinery goes steadily on. The sluice tunnel is finished and a raise is being made from the end of the drift up to the cement and gravel bodies above. Daily yield 65 tons of ore, keeping the mill steadily running.

BELOHER.—Daily yield, 550 tons of ore. The ore-breasts and stopes on all the different levels are both looking well and yielding splendidly. The mills are all running and the future prospects of the mine look brighter than ever.

CROWN POINT.—The ore stopes on the 1,200, 1,300 and 1,400-ft. levels are all looking well and yielding the usual amount of rich ore. Prospecting throughout the mine is progressing with the usual energetic vigor, the mills are all running up to their full working capacity, and the future prospects appear bright and hopeful.

UTAH.—The ledge on the 400-ft. level has been prospected and proven to be over 100 ft. in width, with as finely developed clay walls and intervening matter as in any mine on the Comstock lode. Sinking the main shaft for a new level will be commenced on Monday next. It is the intention to sink 300 ft. before again drifting.

IMPERIAL EMPIRE.—Sinking the main incline is making good headway, the bottom in fair working ground. The main east drift on the 1,850-ft. level has penetrated the west wall of the ledge, and is now running through quartz, with occasional bunches of clay and porphyry. This quartz gives low assays.

GOULD & CURRY.—Sinking the double winze below the 1,700-ft. level is making the usual steady progress. The Burleigh drills employed seem, however, to meet the full requirements of the situation, and enable good progress to be made.

SILVER HILL.—The machinery is all working with the utmost perfection. The up-raise in the old St. Louis chimney from the south drift on the first station level shows a steady im-

provement, and promises the development of a good body of ore.

SUTRO TUNNEL.—The main header is in 5,837 feet, with the face in hard blasting rock. The new Burleigh drilling machines were started into operation on Saturday last. Drifting both east and west from shaft No. 2, on the line of the tunnel will be commenced in about two weeks.

LEO.—The ledge matter continues wide between the walls, and the under ore vein carries several seams of good looking quartz, varying from one to four inches in thickness, which are quite likely to concentrate into an ore body farther ahead.

CALEDONIA.—The main west drift at the fourth station level, to connect with the air winze from the level above, is making rapid headway.

KOSUTH.—The main south drift is in 202 feet, the entire drift running through a solid body of ore for the last 30 feet. In this ore gold largely predominates and a fair average of assays show it to be worth about \$35 per ton.

BALTIMORE CONSOLIDATED.—The shaft is now down 715 feet. The erection of new machinery is at a stand-still for the present, owing to the want of the necessary bed sills and other foundation timbers for the engines, which have not yet been shipped from the mountains.

MINT.—The new hoisting machinery is working with utmost perfection. The shaft is now down 175 feet, and will be pushed rapidly ahead for the opening of a new level.

WOONVILLE.—The sinking during the last few days has been considerably impeded by a strong flow of water, although there is not enough as yet to entirely stop work.

OVERMAN.—The main west drift, on the 1,200-ft. level, is making steady progress, the face in very promising material, indicating a near approach to the main ledge.

CHOLLAS POTOSI.—All work on this lower levels is suspended for the present, in order to renew the foundations for one of the hoisting engines, which was injured by the heat of the fire at the time the hoisting works were burned a year or two since. Daily yield of ore, 130 tons, the assay value of which is \$32 per ton. The ore breasts are all looking well and yielding finely.

SAVAGE.—The material in the face of this cross-cut on the 1,900-ft. level is considerably softer, and shows evident indications of a near approach to the ledge.

SUCCESS.—Sinking the main shaft east of the hill is making fair progress. The shaft is now down 455 ft.

DAYTON.—The ore breasts throughout the entire mine are both looking well and yielding finely. Two mills, Woodworth's and Briggs', are kept constantly running crushing ore from the mine.

SOUTH STAR.—There are over 2,000 tons of ore on the dumps for milling as soon as a mill can be procured.

GLOAZ CONSOLIDATED.—Sinking the main incline is making excellent headway, the rock in the bottom blasting out splendidly. The north drift at the head of the incline is in 25 ft., this entire distance through good milling ore.

BUCKEYE.—The south drift at the 450-ft. level has developed no new or extensive body of ore as yet.

NEW YORK CONSOLIDATED.—Owing to some unavoidable delays the new machinery has not yet been started up, but will be in a very few days. There is on hand at the mine of material and supplies, consisting of timber, wood, iron, steel, tools, etc., the equivalent of \$16,000. Grand total expenses during the year, \$35,000.

FLORIDA.—Assays of ore taken from winze No. 2 range all along from \$16 to \$20 per ton. Working operations are impeded somewhat, owing to the encountering of a large body of water.

UNION CONSOLIDATED.—The face of the north drift on the 1,300-ft. level from Ophir shaft is showing a continued improvement, and promises good ore developments in that quarter when cross-cuttings shall have been commenced.

LADY BRYAN.—Work on this new hoisting works building, and erecting the new machinery is making steady progress.

MO MEANS.—The west tunnel is still making good headway, the rock in the face gradually softening, and showing evident indications of a near approach to the ledge.

LADY WASHINGTON.—The erection of the new machinery is making steady progress, and will probably be ready to resume sinking the shaft by the 10th of next month.

EUROPA.—Sinking the winze from the north cross-cut on the tunnel level is making steady progress, the bottom in vein matter of a very promising character.

ALHAMBRA.—The new hoisting works is completed and the machinery all in splendid running order. Work has been resumed in the shaft.

SENATOR.—The water is drained from the shaft and sinking is resumed.

TYLER.—The shaft is completed to the 300-ft. level, and cutting out for a new station at this level was commenced this morning.

NEVADA.—The south drift from the tunnel level is still showing a steady improvement in the quality of the ore penetrated.

The Pacific Mail Steamship Company save \$13,000 a round trip between this port and Panama by the use of the new screw steamers instead of the old side-wheelers.

AFTER a suspension of nearly two years, work was resumed on the Brownville quicksilver mine, situated about four miles from Vallejo, on Monday.

USEFUL INFORMATION.

Salt and its Uses.

A correspondent of the *Country Gentleman* thus writes of this well-known but not very well understood necessity of life:

Salt is a chemical compound, consisting of 60.68 per cent. of chlorine and 39.32 of sodium. These two substances, thus combined, make pure salt, unless some other thing be combined with them. When other substances enter into the combination, they are impurities—some of them only adding to the weight, and doing no other injury, others destroying the value of the salt as a preserver of meat.

The principal impurity usually found in the salt made from sea water, in the English and French, and in the Syracuse salt, is sulphate of lime, (common plaster of Paris,) which does no other injury than to add to the weight, thus causing the consumer to suppose he has purchased fifty-six pounds (a bushel) of salt, when in fact, according to the extensive chemical determinations of that great authority, Prof. Cook, now in the service of the State of New Jersey, he generally buys in salt made from sea-water 2.04 per cent. of sulphate of lime, in the Chesire, 1.35; in the Dieuze, 1.70, and in the Syracuse, 1.14.

The impurities that injure salt are known as the deliquescent chlorides, so called because they absorb moisture from the air and cause the salt to become damp. Thus the purchaser of salt should take care to see the salt he buys is dry. This is, to men who have no better means of judging, the best test they can have, and even an expert judge would trust his decision quite readily upon the feeling of a handful of salt. If when he closed his hand upon it and then freed the salt it fell apart like dry sand, and there was a sharp, angular feel to the grain, he would say that the salt was free from the injurious chlorides of magnesium and lime. But if the handful of salt retained the form given it by slight pressure, and it felt soft and clammy, he would say it would do to salt cattle, hides and like uses, but that it was unfit to put in butter or to salt beef or pork.

Some of your readers may wish to know more exactly what these chlorides are. For their information I will say that, in connection with salt, they are found in a fluid form adhering to the surfaces of the particles, and may be washed away in the process of manufacture by the use of proper skill and care. So the makers of the salt of the Bay of Biscay, on the coast of France and Spain, place the salt as it is made on platforms, where it is washed, and when it has become hard it is broken up, piled in heaps, and then washed and allowed to drain until the chlorides are carried off.

Chemically stated, the chloride of calcium (lime) consists of 63.35 parts of chlorine and 36.65 of calcium; the chloride of magnesium consists of 73.64 parts of chlorine and 26.36 of magnesium. These chlorides have an exceedingly bitter taste, and not only injure the salt by causing it to imbibe moisture, but, by their acid, eating qualities, causing beef to become hard and dark colored, the rind to slip off from pork when it is boiled. Fish, under their action, become hard, dark colored and tasteless. Butter and cheese have a bitter taste imparted by these substances, and are soon spoiled by them.

Prof. Cook spent much time in the examination of salt, and to know all about the salt of Europe he went there and exhausted the subject, and as the result of his labors the following table of analytical results is given, of the presence of the deliquescent chlorides in the best known salts sold for consumption:

Salt made from sea water, seventy-three parts in 10,000; Cheshire, commonly called Liverpool "stoved," four parts; Cheshire, commonly called Liverpool "common," twenty-five parts; Cheshire, commonly called Liverpool "rough," thirty-seven parts; salt made at Dieuze, (in the northeast part of France,) "fine," twenty parts; salt made at Dieuze, "medium," twenty-six parts; salt made at Syracuse, "solar," four parts; salt made at Syracuse, "boiled," two parts.

Thus Prof. Cook found that the salt of Syracuse was only equalled in its freedom from these injurious chlorides by Liverpool (England) stoved salt, as compared with the "solar," and that the "boiled" salt of Syracuse had only one-half the quantity contained in the Liverpool-made salt; but why should the Syracuse solar salt have four parts to the boiled two? The solar forms in large, irregularly-shaped crystals, that have cavities and sunken places, from which it is difficult to wash and drain the sticky semi-fluid chlorides, unless the crystals are broken down by grinding.

Having Prof. Cook's analysis before them, the salt-makers turned their attention to the discovery of some process by which they could get rid of the impurities, and make pure salt. In this they were successful. Professor Charles A. Goessman, a chemist of established reputation, was employed to perfect the methods that the salt-makers had themselves devised of removing the delinquent chlorides, and the result was pure salt, which was put into the market under the name of factory-titled dairy salt. In 1861, while the processes adapted for making entirely pure salt were much less perfect than they have since been made, some of this dairy salt was sent to Prof. Cook for his opinion. Of this salt he said: "A satisfactory evidence of the purity of salt is its dryness. I have had this specimen in a wooden

salt-box for four months, and still it loses less than one per cent. of water by heating it to melting. Your factory-titled possesses no deliquescent properties, and contains no active substance except pure salt."

Butter, to remain of the first quality, must have salt that is pure, and it is for butter and cheese and table purposes that this exquisitely pure salt is mostly used. The chemical processes to which it is subjected, and the grinding is very fine, add about one-eighth of a dollar to the cost of a bushel—equal to sixty-two and half cents a barrel.

COLORS FOR FIREWORKS.—Those who are interested in home-made fireworks may learn something from the following hints given by the *Scientific American*: Red fire: sulphur, 1 part; sulphuret of antimony, 1 part; niter, 1 part; dried nitrate of strontia, 5 parts. Blue fire: Tersulphuret of antimony, (orpiment) 1 part; sulphur, 2 parts; dry niter, 6 parts. This is the Bengal blue light. Green fire: Boracic acid, 10 parts; sulphur, 17 parts; chlorate of potash, 73 parts. Yellow fire: Sulphur, 16 parts; dry carbonate of soda, 23 parts; chlorate of potash, 61 parts. Violet fire: Charcoal, 8 parts; sulphur, 10 parts; metallic copper, 15 parts; chlorate of potash, 30 parts. Orange fire: Sulphur, 14 parts; chalk, 34 parts; chlorate of potash, 52 parts. Purple fire: Lampblack, realgar and niter, of each 1 part; sulphur, 2 parts; chlorate of potash, 5 parts; fused nitrate of strontia, 16 parts. By parts are meant equivalent proportions, ounces, pounds, etc. The different ingredients are to be separately reduced to powder, sifted through lawn, and kept in well corked wide mouthed bottles until used. Care must be exercised in handling, especially the chlorate of potash, when in contact with combustible materials. The materials must be carefully mixed on a sheet of paper with a wooden stirrer with a light hand, avoiding excessive friction. They should not be mixed long before using, as they are apt to deteriorate by long keeping and even to inflame spontaneously. The nitrate of strontia, alum, saltpeter and carbonate of soda, before being weighed, should be heated until their water of crystallization is driven off and they fall to powder.

CANNON MADE OF ICE.—A hollow cylinder will bear a greater strain than a solid one. Many of us know by experiment what a hard pressure an egg will resist when placed endwise between the hands. This curious strength in a round but weak substance is due to the exact, orderly arrangement of the particles, i. e., in perfect curves. A memorable illustration was seen in the mock artillery set to play guard in front of that creation of imperial whim, the ice palace of Catharine of Russia. Before the palace stood six cannons of ice, and two mortars formed of cast pieces. The cannons were six-pounds, which are commonly loaded with three pounds of powder; these, however, with a quarter of a pound, and carried a ball of stuffed hemp, and sometimes of iron. The balls, at a distance of sixty paces, passed through a board two inches in thickness, the ice of the cannons could not have been more than three or four inches in thickness, and yet it resisted the force of the explosion.—*American Manufacturer.*

In kerosene lamps the light often is unsatisfactory while all is apparently in good order. It should be borne in mind that, though the wick is but very gradually burned, it is constantly becoming less able to conduct oil. During several weeks some quarts of oil are slowly filtered through the wick, which stops every particle of dust or other matter that will with the utmost care be in the best kinds of oil. The result is that the wick, though it is of sufficient length and looks as good as ever, has its conducting power greatly impaired, as its pores, so to speak, or the minute channels by which the oil reaches the place to be burned, become gradually obstructed. It is often economy to substitute a new wick for an old one, even if that be plenty long enough to serve for some time to come.

TO PREVENT THE RUSTING OF IRON.—A correspondent sends us the following suggestions: I have tried many things, but found nothing better than boiled linseed oil to protect instruments and tools, (files, saws, guns, etc.) from rusting. It even works the best with a kettle used for heating water for bathing. Wipe the metal with a cloth dipped in the oil, and let it dry, which will require only a few minutes. If it is unnecessary to have the iron bright and shining, you need not scour it before the application of the oil; this will combine with the rust and form a firm, durable coating.—*Journal of Chem.*

RAISING WRECKS.—In raising sunken vessels, it has been common to use flexible air-tight bags, which, when properly secured to the vessel, are inflated with air by pumps. A recent improvement, by Mr. Sowerbutts, of England, consists in supplying acid and alkali to the bags, which, on being mixed, generate carbonic acid within the bags and produce the necessary inflation, no air pumping being necessary.

WHEN fuel is burned in an open fire place, at least seven-eighths of the actual or potential heat passes up the chimney unused; about one-half being carried off with the smoke, and one-fourth with the current which flows in between the mantel-piece and the fire, while the remaining loss is represented by the unburned carbonaceous matter in the smoke,

GOOD HEALTH.

Brief Thoughts on Habit.

Our habits are the best illustration we can give of the very intimate relation between our minds and our bodies.

1. Every person has his modes of thought and action, and these are but habits which we have inherited from our ancestors, or acquired ourselves. Indeed some physiologists go so far as to teach that the reason why the body grows up as it does, is because of the power of habit for ages.

2. It is a matter of universal experience that training for special aptitudes is more effective when exerted on the young and growing child, than when brought to bear on the full grown man or woman. The training in early life gives the organs of the body a tendency to grow to certain modes of action. In after life these modes of action are difficult to acquire. In other words, we find it easy and almost automatic to do what we have done before, and to think and feel what we have thought and felt before. This tendency is stronger in the nervous system than in the other organs of the body.

3. The reason why old people remember so much more distinctly what they learned in early life than that most recently learned, is because the force of habit, while the body was in its full vigor, has fixed these impressions more thoroughly in the nervous tissues of the growing brain. They endure to the end of life.

4. In mature life it is difficult to form new habits of thought, or to master new subjects, unless they fit in with what we have already learned. Things seem very unreasonable to us that do not match with our previous knowledge, though they are perfectly true, measured by the standard of those who have formed different habits of thought.

5. Habit shows its power over both mind and body concerning the things we eat and drink. People who, from long habit, have got used to certain articles of food think they cannot live without them. They are used to them, and whether best or not is a question never to be thought of.

6. It is more than probable that the habit of drinking liquors would never be acquired to any great extent after the age of thirty. Let a boy be well fed and know nothing about the use of alcoholic beverages till a man, and he would rarely form the habit of using them. "I once knew a family reduced to poverty," says Carpenter, "who declined to eat a rich barley soup because they were not used to it." It was hard to form a new taste after the habits of the body and mind had become fixed. The same writer gives another case where all the workmen of a large outfitting establishment refused to work because they were required to make a slight alteration, not more troublesome, in the pattern of a particular garment. And still another of an effort on the part of manufacturers of cheap prints for the humbler classes, to change the styles a little, which failed. They had been in the habit of wearing a particular pattern so long it had become a part of themselves. The least departure from it could not be tolerated. The tissues of the body get into bad habits as well as the nervous system. After nasal catarrh has once been established it is often kept up from mere force of habit. People cough from habit, spit from habit, go to sleep and wake at particular hours from habit. We once knew a thief who stole from habit. His faculties were used to working in this way and could work in no other.

7. Where habits are wisely and judiciously formed in early life the tendency is an extremely useful one, enabling us to work with ease instead of with difficulty. Habit renders all things easy. Without habit it requires a strong will to bring us up to the point of doing what we ought to, or must do.

8. It is not wise to be a slave to even good habits; to be so we cannot do any work except in a particular way, sleep except in a particular bed or room, or eat only a particular food.

9. To break up a bad habit requires a powerful effort of the will. Nothing so weakens this faculty as the force of bad habits. Every victory of habit over the will leaves the victim weaker and weaker, till at last his power of resistance is completely annihilated.

10. The formation of habits should begin with birth, especially as regards eating, drinking and sleep. The regularity of these early bodily habits will help to shape the mental habits of after life. Nothing tends so to develop the vice of self-indulgence in children so much as to allow them to eat, sleep, study and play when they please, without reference to order and discipline. A mother related a case to me the other day, of her child, which had been used to nursing twice during the night, thus disturbing the sleep of the mother and injuring her health. She resolved to break up this habit. The first night the child awoke as usual for its food. The mother refused it, and the result was two hours of lusty squalling. It almost made the mother relent, but she persevered. The next night the same was repeated, only in a less degree. The third night the child did not cry over ten minutes, and this was the end of all her trouble. The child did not reason on the subject; it had no will in the matter. The strong force of habit made it cry for its accustomed food at a certain hour, and as soon as a new habit was formed it took the place of

the other, the little fellow being equally satisfied. Mothers would save themselves much care and trouble if they would study the subject of habits thoroughly, and then adopt a wise course with their little ones.

11. Military drill in schools for the young, or gymnastic drill, has great value, from the fact that it not only promotes a healthy physical development, but it helps to form habits of strict order and prompt obedience. When soldiers go to battle if strict discipline is maintained they can lead a forlorn hope; but the moment the ranks are broken, if they cannot form again, all is lost.

12. The habit of doing its duty is a very important one for a child to learn. It generally has a good idea of its own rights, but knows nothing of the rights of others. Duty teaches this, especially when right and justice are made a part of it.

13. Lastly, love and affection should grow into habits. Fathers and mothers, sisters and brothers must set the example. There is no moral health or happiness without love. It is the mainspring of all healthy action, the greatest power given to human beings.—*Herald of Health.*

THE CINCHONA ALKALOIDS.—Dr. H. C. Wood, in his excellent "Treatise on Therapeutics," just issued, has the following remarks on cinchona:

"The physiological action of cinchona is similar to, but less powerful than that of quinia. Thus Conzen (quoted by Husemann) has found that its action on infusoria and on fermentation is similar to but weaker than that of its sister alkaloid. Upon dogs, according to Bernatzki's experiments, the lethal dose of cinchona is to that of quinia as 5 is to 4. The history of cinchona in the organism appears, therefore, to be parallel with that of quinia.

As an antiperiodic cinchona exerts a similar influence to quinia, but is probably about one-third weaker than that alkaloid, and must be used in correspondingly larger dose. Dr. J. B. Hamilton (*Indian Medical Gazette*, November, 1873) affirms as the result of experiment that cinchona as a prophylactic against malaria is very superior to quinia.

As a tonic I have never been able to perceive that cinchona acts differently from quinia.

The London *Lancet* (February, 1873), referring to the cinchona alkaloids, says: Considering the expense of quinine, it is somewhat surprising that these alkaloids have not been more generally used in the treatment of malarious fevers, especially as there does not appear to be any doubt in the minds of those who have tried them as to their efficacy."

MILK DIET IN DYSENTERY.—Dr. Barret states in the *Archives de Medecine Navale*, that he has made use of milk in chronic dysentery among soldiers and sailors returning from China. He considers a milk diet superior to all other treatment in such cases. The milk must be pure, unmixed with water, as fresh as possible, and not boiled. Sufficient milk was given to a patient, but nothing else allowed to pass his lips. Diarrhea, if it appears, lasts but a few days. No change of diet is to be made, and no medicine given. If the physician fears the persistence of the diarrhea, a small quantity of bismuth may be prescribed. If the milk pass through the bowels undigested, pepsin will remedy the defect in the digestive process. After a time the faeces become solid, the patient thinks himself cured, and craves other food. This is the dangerous period, for too early relaxation of the diet may cause a relapse. White of eggs, rice cream, and the lightest possible things are to be admitted sparingly; and when the patient feels convalescent, and will endure the restrictions no longer, he is to return by the slowest degrees to his former diet.

THE NEW BLOODLESS OPERATION.—The plan of operating lately introduced or revived by Professor Dittel, of Vienna, appears to have become suddenly fashionable. The London *Lancet* gives an account of the mode by which it was suggested to Dittel. It seems that some months ago he was called to see a young girl who was suffering from severe nervous symptoms, and who was evidently dying. Next day, on making a post-mortem examination, he found that the rubber band of a hair net which had been worn day and night for a month was deeply imbedded in the pericranial tissues, and had in one part cut through the walls of the skull and was pressing on the dura mater, which was in a state of acute inflammation. On inquiry it was ascertained that the girl had a cruel step-mother, who greatly objected to the loose and dishevelled looks of her daughter, and insisted, therefore, on the child wearing a net to keep the hair in place.

USE OF LEMONS.—When persons are feverish and thirsty beyond what is natural, indicated in some cases by a metallic taste in the mouth, especially after drinking water, or by a whitish appearance of the greater part of the surface of the tongue, one of the best "coolers," internal or external, is to take a lemon, cut off the top, sprinkle over some loaf sugar, working it downward into the lemon with the spoon, and then suck it slowly, squeezing the lemon and adding more sugar as the acidity increases from being brought up from a lower point. Invalids with feverishness may take two or three lemons a day in this manner with the most marked benefit, manifested by a sense of coolness, comfort and invigoration.

TABLE OF CONTENTS.

GENERAL EDITORIALS.—Society of Engineers of California; Improved Truss for Bridges; California Earthquake and Stone Wars; Litigation Among the Powder Companies, 289. Placer County Mining News—Banks, Blasting, Etc.; Mining Education in California; The Negley Amendment; Poison Oak Remedies, 298. Improved Hydraulic Motor; Improved Chimney Stacks; Congress and the Patent Laws, 297. Telluride Ores on the Mother Lode; Academy of Sciences; Patents and Inventions, 300. **ILLUSTRATIONS.**—Graham's Improved Braces for Truss Bridges; Section Showing Braces, 289. Walter's Hydraulic Motor; Brownell's Improved Chimney Stacks, 297. **CORRESPONDENCE.**—Notes of Travel in Colorado Territory; Robinson District, Nevada, 290. **SCIENTIFIC PROGRESS.**—Photographic Engraving; The Coming Transit of Venus; Nitrous Oxide; What is Steel? The Active Principle of Yeast; Preparing Ammonia Salts, 291. **MECHANICAL PROGRESS.**—Puddles Walls; Improvement in the Manufacture of Floor Cloths; Copper Bolsters; A New and Practical Improvement in Umbrellas; A Chance for Inventors; Boat Pumps, 291. **MINING STOCK MARKET.**—Tables of Daily Sales and Prices and Comparative Prices for the Week; Notices of Assessments; Meetings and Dividends; Review of Stock Market for this Week, 292. **MINING SUMMARY** from various counties in California and Nevada, 293. **USEFUL INFORMATION.**—Salt and its Uses; Colored Fire; Cannon Made of Ice; To Prevent the Rusting of Iron; Raising Wrecks, 295. **GOOD HEALTH.**—Brief Thoughts on Habit; The Quincha Alkaloids; Milk Diet in Dysentery; The New Bloodless Operation; Use of Lemons, 295. **MISCELLANEOUS.**—Transit of Venus Parties; Cinnabar Mining District; Sacramento Smelting Works, 290. The Pine Flat Quicksilver Mines; S. F. Refining Works; Mineral Land Decision; Relative Size of Blood Corpuscles; New Hot Water Tunnel; State Mineral Lands; American Flag Mine, 294. Metallurgy of Bismuth; Klamath County Mines; Charcoal Coke for Smelting at Eureka; Pioche Mines; The Prospector, 298. Five Millions of Dollars for our Sugar Annually; Wyoming Iron, 299.

Are We to Have a Flood?

The unusual continuance of the spring rains the present season, may well suggest the heading of our article. In the earlier days of California it was not unusual to see our larger mountain streams overflowing their banks in May and June, and completely submerging the whole tule country of the Sacramento and San Joaquin rivers. The occurrence, when it did happen, was in seasons in which large quantities of snow had accumulated upon the Sierras during the winter, to be suddenly melted by late and warm rains, to be sent in torrents to the valleys, and, on their way, flooding the alluvial of the rivers, to the great destruction of the farmers' crops, and sometimes the property of cities upon their borders.

That Sacramento is perfectly safe from any future flood we have not the least doubt; but how is it with those fine, extensive alluvial that border the American river? We hope they may experience no overflow, though we are not without misgivings. The best of the reclaimed delta islands, Sherman and others, will doubtless stand firm in their levees, and thus escape the damaging effects of former overflows; but should it be otherwise, an immense amount of damage to growing crops would be inevitable.

CALIFORNIA RICE CULTURE.—Mr. J. H. Taylor, of Livermore, has some three acres of upland rice now growing and looking finely. He sowed 100 pounds of seed obtained in New York, and two pounds from the Agricultural Bureau, at Washington. Several years since, Mr. T. sowed one pound of seed, which grew well until two feet in height, when it was destroyed by stray stock, that devoured the straw with avidity. Mr. T. has sowed this experimental crop broadcast, but recommends sowing in drills, 18 inches apart. He believes the upland rice will grow on any good barley land. We invite him to furnish us the result of his pioneer efforts in rice and cotton raising at Livermore.

The work of rebuilding the burnt district, at Colfax, Placer county, has commenced.

Placer County Mining News—Banks, Blasting, Etc.

Mr. J. H. Brown, of Forest Hill, Placer county, has several men at work on his claim, the New Jersey, a mine only needing development to yield rich returns. Mr. Brown, who is probably the "oldest resident" on the divide, having been there since 1851, affirms that capital only is wanting to make the Forest Hill mines as profitable as they were in 1859 and 1860.

At Forest Hill on the morning of April 29th, at 8 o'clock, Mr. N. J. Kabath, of the firm of Kabath & Ladd, agents of the Lafin & Rand Powder Co., fired by electricity the largest blast that has ever been shot off on the divide. The claim operated upon is known as the "Paragon," situated at Bath, and owned by Wheeler and Breese. The amount of powder used was 700 kegs, or 17,500 pounds. The blast was acknowledged by many practical miners who

witnessed it, to be the most successful and effective that had taken place in that section. In preparing the ground for this blast, drifts were run in the shape shown in the preceding diagram.

The drift from the face of the bank was 110 feet long. From the end of this a drift was run one way 70 feet, and the other way 60 feet. From the end of the 70-foot drift an L was run towards the face of the bank 55 feet; from the end of the 60-foot drift a short drift, 30 feet long was also run back towards the face of the bank. In the drift to the right 400 kegs of powder were placed, and the opposite side, 300 kegs. The mouth of the drift was tamped for 75 feet from the near end, and the T drifts were tamped 10 feet each way. Plenty of space was left in the L drifts for the expansion of gases generated by the explosion of powder. The tunnel was 4½ feet high and five feet wide, and the bank was 140 feet high. The electrical apparatus by which the blast was fired was 450 feet from the mouth of the tunnel. The whole length of wire was about 1,500 feet.

It will be seen from the cut, and what has been before remarked, that there was 25 feet of tamping—ten feet on each side and that in the width of the tunnel—between the two L drifts, not counting the 75 feet between that and the outer air. If this blast had been fired by means of fuses, and one side had gone off before the other, much less execution would have been done. Being fired by electricity, the discharge was simultaneous and was exerted on both sides of the tamping at the same instant, so that the explosive force of the powder was exerted in the proper direction only. The powder was placed in the drifts in iron kegs. The drifting necessary to put off this blast cost \$300, and powder, materials, etc., cost \$2,700 more. As the owners estimate that from the effects of this single blast, they will be able to clean up about \$200,000, the outlay of \$3,000 was extremely small in view of the benefits derived. The system of bank blasting will probably double the consumption of powder in California in a few years, with good results to the miners.

The Dardanelles claim, owned by Mr. Jones, is panning out well. It is stated that \$80,000 has been offered for this claim by a San Francisco company, but \$100,000 is asked. The last clean-up for a run of one week was \$9,000. This was last week; the gold weighed 30 pounds.

At Michigan Bluffs, the Big Gun claim of Van Emmon & Bros., gives employment to 20 men. The "Whisky" is making preparations for a new start, and expect a rich strike. Some \$45,000 has been expended on the Hazard claim, owned by a San Francisco company, and they are now doing well.

The Meares, Pond, at Todd's valley, are working several claims, which are paying them well.

At Yankee Jim's they expect a busy time this season.

The toll roads between Auburn and Forest Hill are in excellent condition.

MINING SALE.—A cotemporary states that Dr. A. Anderson, of Vallejo, has been one of the lucky ones connected with the cinnabar excitement in Lake county. He has disposed of a mine, in which he has a half interest, for \$20,000. This mine is known as the Sulphur Bank, and is located on the Clear Lake shore, two miles from Borax Lake.

The water has been turned into 4,100 feet of new pipe just laid by the Northerly Five Cent Hill Mining Company. This will be of benefit to the placer mines in the vicinity of Greenwood.

Mining Education in California.

We recently made some remarks to the effect that there was no better place, perhaps, in the world, for the student of mining engineering in all its branches, than at our State University, providing the necessary facilities for pursuing studies were furnished. Of course, as far as the acquisition of book knowledge is concerned the locality where the student "absorbs" such knowledge is of no moment; but in this study, more than all others, a practical education is necessary and students must be able to make geological tours, visit mines and mills in operation, have a well-furnished chemical laboratory and a good mineralogical collection close at hand, and above all good, practical and efficient instructors.

Since the former article referred to was published, the Regents of the University have decided, among other improvements, to commence the instruction in mining at the University, and a special committee is to be appointed to consider and report what is feasible. There are to be in the University two Faculties, one of Letters and the other of Science. The Faculty of Letters shall maintain two courses of instruction, one corresponding to the usual classical college, and one in which special prominence shall be given to the modern languages and literature. The Faculty of Science shall maintain five courses of instruction, which shall be announced as colleges, namely, the College of Agriculture, the College of Mechanic Arts, the College of Mining, the College of Engineering, and the College of Chemistry. Plans shall be taken to make the instructions in each of these thorough, systematic and complete. Scientific students may be required to attend some literary studies, and literary students may be required to attend some scientific studies, in order that a liberal culture as well as special proficiency may be attained.

In carrying out the plans proposed it is to be hoped that the committee will consult with a few practical mining men as well as those connected with educational institutions. If every effort possible is made to cause this department to be as practical as is consistent, it will be of great value to the State. The students ought to know how to handle a pick and shovel, put in a blast, place a set of timbers, lay tracks and lagging, sharpen a pick or drill, and do other things of like character that every common miner knows. They ought to be able to replace a shoe or die, prepare their plates, regulate the cams to get the right drop, know how much quicksilver to put in a battery, charge a pan, clean up a battery with plates, blankets or pane, retort the amalgam, make a bar, clean the quicksilver, and do the general work around a mill. We mention these, since they are subjects frequently neglected in favor of more scientific knowledge.

When young men are advanced far enough to be able to get a position as superintendent of a mine or mill they will not have to do such work as we mention, but until they are able to get such a position they must expect to accept subordinate places. The great fault with most of them is that they suppose themselves capable of accepting positions of superiority as soon as they leave school, and are rather surprised and offended if they do not get an opportunity to display their talents. The truth is that in the mining regions, scientific miners are looked down upon unless they prove by their works that they are fully as well posted in minor details as in more advanced knowledge. When they are known to possess the necessary qualifications of both the common miner and the educated metallurgist, they will be recognized according to their merits.

If our university can succeed in sending out young men fitted to accept any position about a mine or mill, it will have accomplished much good; for the advanced and theoretical knowledge of such, after being increased with experience, will create a class of men much needed. The university has a good laboratory, a quartz mill has been given to it, and now it wants samples of all the improved machinery of the day. Means should be provided for the students to take extended trips into the mining regions where large operations are being carried on. Will not some of the many gentlemen who have made their fortunes from the mining interests of this coast have generosity enough to start this fund with a liberal donation? If properly inaugurated, others may become willing to aid the cause and build up a department of mining in the university which shall be a credit to the State. Who speaks first?

GUERREVILLE mining district, in Sonoma county, the seat of the latest quicksilver excitement, commences at a point on Russian river, at the mouth of what is known as Porter creek, thence along said creek to the head of the main branch, to the head of East Austin creek, thence west on a line to West Austin creek, thence southwest to Poll Mountain, thence south to the mouth of Russian river, thence up said river to the place of beginning.

COMSTOCK ORE.—The following is a statement of the amount of ore shipped by rail during the month of April from the Comstock mines to the various mills in the vicinity: Number of car loads, 3,772; number of pounds, 56,580,000.

The new town in Highland district is to be called Williamsburgh.

The Negley Amendment.

"There are none so blind as those who won't see," and a majority of the papers on this coast are perfectly blind with respect to the effect of the different mining bills now before Congress especially the Negley amendment. They persist in calling it the "Sutro amendment," and state that it is wholly in his interest, simply because a clause in the amendment specifies that the rights of the tunnel company "shall not be in any way affected." Common sense is not enough to teach any one that if there is no clause in an amendment which changes any former law, the former law will stand as it is; and in this case there was no need for the clause quoted above, as the vested rights of the tunnel were not affected by it. Commissioner Drummond, of the General Land Office, in a letter publicly states that so far as the rights of the tunnel are concerned, the amendment does not change any existing law, and that Sutro's rights are as good now as they will be if it passes.

The only question at issue is this: "Shall the productive Comstock mines define their boundaries?" The owners do not want to do so, and because Mr. Sutro supports this amendment—somewhat unadvisedly, we think—and he is an unpopular man, as most persistent men are, the owners of these mines desire to make the bill odious by throwing it on to his shoulders. Sutro naturally wants to protect whatever rights he has under the law, and no one can blame him for so doing; but if he had not made himself so prominent in this matter, the question might have been better understood.

The idea of Mr. Sutro "running" Congress is twaddle. Rich men like Jones and others would do it if they could, but because they cannot, they pitch into Mr. Sutro because Congress wants to recognize rights which a former Congress has conferred. There is a large amount of telegraphic "boob" on this subject coming from Washington from day to day, and so very one-sided that it looks to impartial observers as if the owners of those productive mines had captured the sender of these dispatches. We are glad to see that the *Chronicle* of this city has been just and fearless enough to speak the truth about this matter and has suppressed many of the foolish statements forwarded to it. Many of the other papers, in their enmity to the tunnel scheme, have mis-stated the whole case.

If these productive mines on the Comstock define their boundaries as this bill compels them to do, many more mines will be patented and worked than at present, the titles of those claims to the eastward will be settled and they will be marketable, which they are not now. There is no reason to tug in the Sutro question at all, whatever his rights are they are not affected. The statement that suit will be begun by the Comstock mines against the tunnel is improbable, as there is as yet no cause for suit. When the tunnel reaches the lode and the royalty is demanded there will be time enough to renege the demands in the courts; at present there is no cause to.

Poison Oak Remedies.

A lady recently informed us that "soap root," which grows wild in most hilly districts in California, macerated and applied, gives almost instant relief to the surface affected by poison oak. As soon as dry it seems to form an airtight covering. We have seen it tried with effect; but as to whether in bad cases it is sufficient without any further means of eradicating the poison from the system, we can not say. Mrs. Sherwood writes to the San Francisco *Call* as follows: "We tried several cures, but all failed but the following, which was sent from your paper. It did not act so quickly as promised in the recipe, but was very effective:

"Dissolve one ounce of gum shellac in six ounces of sulphuric ether; cork tightly in a bottle. Bathe the surface where the irritation appears with cold water, and wipe dry; then apply the above ointment. The ether will evaporate, leaving an elastic coating of gum, impervious to the air. In about two minutes the most distressing case of poison oak can be relieved entirely of all unpleasant sensations. As the coating peels off, apply more of the ointment, and in twenty-four hours the cure is performed."

[We presume that collodion, which is gun cotton dissolved in sulphuric ether, will answer the same purpose. It may be obtained at any druggist's, and when applied to the surface with a brush, immediately forms a thin coating impervious to air or water.—En: CALL.]

The last angustion on this subject is that a simple mustard plaster answers all purposes in effecting a cure for poison oak.

The San Francisco Microscopical Society held its annual reception on Monday evening last, when a number of microscopical specimens were exhibited to the guests. The society is now in a flourishing condition, has a good membership and several very handsome instruments, which latter are not put away under glass, but made good use of by the members.

The St. John quicksilver mine near Vallejo, Solano county, produced 192 flasks of mercury in April, worth about \$22,000.

Improved Hydraulic Motor.

The accompanying illustration represents an improved hydraulic motor, invented by Wm. Walter, of Arkada, Washington Territory, the object of which is the utilization of the power of small streams of water for various purposes, with or without requiring dams, as all the water can be conveyed through flumes or pipes. The inventor claims that, by the use of his invention, small streams, which have hitherto been useless for water-power, may be applied to impart motion to stamping, pumping, sawing, and other machinery. The invention consists in the application of the stream or body of water to a vertical cistern and cistern-valve, which is balanced by a weighted lever, so that, on floating, the water rushes into a horizontal pipe and trough, filled with water. The forward motion of the water, in connection with the closing of the cistern-valve, produces a forward motion of a piston-valve at closed end of the horizontal pipe, which is connected suitably to the machinery to be driven by it.

The drawing represents a vertical longitudinal section of the motor. *A*, is a trough or ditch, constantly filled with water; *B*, a horizontal pipe placed lengthwise therein, the shorter end, *a*, of which has a larger diameter than the longer end, *b*. To the wider part of the pipe, *B*, is connected, in a suitable manner, the vertical cylindrical cistern, *C*, having about the same diameter as the pipe, *a*. Its upper funnel-shaped end, *d*, conducts from the pipe, *c*, the stream of water to the cistern, *C*. The shorter end, *a*, of the pipe, *B*, is closed and provided with a well-fitting piston-valve, *D*, which is connected in some suitable manner to the machinery to be operated. The end of the cistern, *C*, communicating with the pipe *A*, is provided with a ring, *g*, rigidly connected to the cistern, *C*, the opening of which is about half of the width of that of the cistern. A cylindrical body or valve, *E*, of wood or other material, as heavy as water, extends through the full length of the cistern, *C*, its diameter being of such width that one-half of the volume of the cistern is taken up by it. The valve, *E*, is pivoted at its upper end to a lever, *F*, sliding in a guide-rod, *h*, and having its fulcrum in standards, *G*. To the other end of the lever, *F*, is suspended a weight, *W*, slightly lighter than the valve, *E*. A projecting band-spring, *i*, acting on the stop, *k*, of the standards, *H*, accelerates the down-stroke of the valve, *E*.

The operation of the motor is accomplished by filling the trough, *A*, pipe, *B*, and cistern, *C*, with water; the valve, *E*, closing the opening of the cistern in the ring, *g*. When the stream fills up the cistern entirely, the valve, *E*, will float as soon as there is some pressure from below to start it. By lifting it slightly the water in the cistern will rush under the valve, *E*, and carry the same upward. It will, in one or two moments, pass through the ring, *g*, into the larger part of the pipe, *B*. The valve, *E*, having no floating pressure from below, in connection with the action of the spring, *i*, of the lever, *H*, on the stop, *k*, is carried back and closes the ring, *g*. The water in the pipe, *B*, being in rapid forward motion or current, causes, by the sudden closing of the valve, *E*, the forward motion of the piston-valve, *D*, with power created. The return of the piston, *D*, by means of the spring, *j*, draws the body of water back, and gives, therefore, pressure enough to float the valve, *E*, and repeat the same operation.

The power of the motor may be used fast or slow, as required—30 to 45 strokes a minute, down to one stroke in ten minutes—with but slight alterations in the proportions of the parts. The power may be utilized in crushing quartz and stamping bones, sawing with sash saw, pumping, etc.

The inventor tells us that in building the machine, the piston, *D*, opening in the ring, *g*, and pipe, *B*, are the same diameter. The length of the pipe, *B*, is about three times the height of the cistern, *C*, or fall of water. Lumber, very thick and strong, is the cheapest material for the cistern and pipe for a large motor, well fastened to the solid mud sills. If made of lumber, (square), the ring, *g*, is not needed and the enlargement of the pipe, *B*, can be made inside of the same and only into two of the planks. Really it is not necessary at all, for it is merely for a stop to the piston, which stop can be made outside and have no head to the piston.

In the trial made by the inventor, *A* was made five feet high and six inches in diameter, and the pipe, *B*, was 14 feet long and three feet in diameter. The mechanism was very poor, and the piston roomy, but it raised a stamp weighing 24 pounds, six inches high. Two quarts of water will escape per stroke, in slow motion. The inventor thinks more perfect workmanship would permit the motor to turn a crank with a fast motion, the fall of the head to force the piston one way and the snout the other. The spring, *i*, must be made so that it can be fastened long or short, and the machine can be regulated with the spring and weight.

The slow motion is caused by a spring catch to the valve, *E*, or lever, to catch, until a float in the cistern will touch it off again. The valve, *E*, is provided with a guide-rod, *h*, on top, to keep the same in its place. The spiral spring, *F*, is not needed when machinery is attached, as it shows in the drawing, but there will be another place found for it in fast motion. In slow motion a mere weight will do to bring it back,

Improved Chimney Stacks.

We illustrate in this issue an improved form of chimney stack, recently patented through the Scientific Press Patent Agency by J. Browell, of this city. The main features of the invention are its strength and lightness. In a country like this, where we are frequently subject to earthquakes, chimneys constructed on the principle of this one are less dangerous than the heavy brick structures in such general use. Mr. Browell claims that his chimney is earthquake proof, and is at the same time efficient for the purposes for which it is made. Fig. 1, in the cut, represents a perspective

WALTER'S HYDRAULIC MOTOR.

view of chimney; Fig. 2, part of chimney with ventilator; letter *A*, the base upon which chimney, *B*, rests, which is usually above the fire-place. The sections of chimney, *C*, *C*, *C*, are constructed of fire-clay, earthenware, cement, or artificial stone, which are made in the form of a tube and placed one upon another. For protecting and securing the joints,

works, 600 feet long, which has 250 feet pressure, giving a good hydraulic force. Four hydrants are attached, with 250 feet of carbolized hose, to be ready in case of fire.

The laborers employed at some mining works in Missouri are debating the question as to whether, when the whistle blows for dinner, they

BROWELL'S IMPROVED CHIMNEY STACKS.

a metallic band or ring, *d*, is employed; the annular channel is filled with cement or other hardening fire-proof substance, which hermetically seals the joints and fixes the bands in place. Outside of the chimney, *C*, *C*, *C*, is a metallic tube, *G*, which is larger than the chimney, *C*, *C*, *C*, so that space is left between the two for ventilation. The rods or bars which secure the chimney are represented by *R*, *R*.

The construction of the chimney is easily seen by referring to the cut. In the manner which it is made, a chimney can be put in the second story of a house or anywhere else, without the necessity of building from the ground. The longitudinal rods have the effect of keeping the stack perfectly firm and solid. The weight of a chimney is very sensibly diminished by using one of this construction. They can be readily set on any fire-place, or outside of brick or frame buildings; in fact, can be placed in any part of the house with perfect safety, without going to the foundation. They can be applied to cooking stoves, ranges, blast furnaces, pottery kilns, etc. The sections of pipe are joined together in their upright position in a novel manner, and the joints are thoroughly protected. The chimneys can be transported readily from one place to another, and can be set up by any mechanic.

For further information concerning this chimney, address the inventor, Mr. J. Browell, at No. 442 Jackson street, in this city.

UNDERGROUND CONNECTION.—The Gold Hill News of the 22d, in speaking of the California mine says: The connection between the north drift on the 1,300-foot level and the south drift on the same level, will be complete by to-morrow morning. The connection of these drifts is quite an important event as there will then be a complete underground connection of all the mines on the ledge extending from the Ophir on the north to the south line of the Hsie and Norcross.

The Consolidated Virginia Company have laid a six-inch water pipe to their crushing

Congress and the Patent Laws.

This week the following dispatch came from Washington to the daily press: The bill reported from the Committee on Patents authorizing the extension of the patent to John Marsh for a trimming attachment to sewing machines, passed, 95 to 85, after a long discussion.

Here then is another case upon which those opposed to the patent system of the country will seize, to illustrate the evil effects and monopolizing influence of patents, when the Patent law is not to blame, but rather the Congress that will not let the patent law alone. In a recent issue of the *Bulletin*, we noticed an editorial on this subject headed, "The Protection of Inventors," which, although true as far as it went, did not fairly state the whole facts, and especially that portion which goes to show the real cause of the trouble complained of. It is an easy task to pick out certain special cases and use them to illustrate the evil working of any law, no matter how just that law may be in the generality of cases. In the article referred to, the India rubber patents and sewing machine patents are employed to illustrate the monopolizing character of patents, when the fact is, that these patents would long ago have been thrown open and free to the public by the expiration of the patents protecting them, had not Congress by special act extended them. This being the case, the monopoly of these inventions can be attributed to special legislation and not to the system of granting patents for original inventions.

No one will assert for a moment that the inventor or discoverer of the process of vulcanizing India rubber, or the inventor of the sewing machine was granted more than he deserved when the exclusive privilege of working his invention for fourteen or seventeen years was given to him, if that privilege had ended when the patent expired; but if Congress saw fit to extend the patents after that time, we do not see how we can attribute the monopolizing influence which that extension created to the patent law. The trouble is with Congress, and not with patent law. If a man discovers or invents something that was not known before, and by that discovery or invention produces something of value to the world, is it not right that he should be benefitted by the results? The world got along quite well before he made the discovery or invention, and it is not going to be greatly inconvenienced by having to pay the small amount of profit in the shape of royalty that is imposed on patented articles for the term or duration of a patent. We agree that in some particulars our patent law can be improved, so as to benefit both inventors and the public; but the idea of Congress, as is proposed, passing a law establishing a fixed royalty of ten per cent. on all patent inventions, irrespective of their value characters, is to us a gross absurdity. Few inventors will devote their time and expend their money in investigating and experimenting upon new ideas, if their reward is to be thus curtailed.

THE COINAGE AT THE SAN FRANCISCO MINT in April was \$1,752,000, making \$7,983,000 for the first four months of this year. Of this total amount \$6,940,000 was in double eagles; \$793,000 in trade dollars; \$143,000 in half-dollars; \$98,000 in quarter dollars; and \$9,000 in dimes.

MONTEREY COAL.—Reports from the newly discovered coal fields near Monterey are very cheering. Investigation has proved that large, well-defined ledges of a superior quality of coal exist there, and that the coal is easily extracted, and lies convenient to a cheap and rapid route of transportation to a market.

MINERS' STRIKE.—Late advices from London state that there seems to be no prospect for the settlement of the strikes at Durham Crossing. Seventy thousand miners and laborers are now out of employment, and great distress prevails among them. Many are preparing to emigrate.

Sacramento men who have a fancy for mining enterprises appear to have quite generally dropped gold and silver hunting, and are now getting interested as fast as possible in quick-silver claims.

Lewis, Bnll & Co., owners of the famous Legal Tender Silver Mine, in Montana, have negotiated in the East, for concentrating machinery, which will be shipped and placed in operation at Clancy, the present season.

PLACER mines have been discovered on the head waters of the Bruno, about 70 miles northeast of Elko, Nev. They are said to be "Chinese diggings," which will not pay white men to work.

ASSAY OFFICE AT HELENA.—The bill providing for the establishment of an assay office at Helena, Montana, has been passed by Congress.

New placer diggings have been discovered below the mouth of South Boulder, in Jefferson county, Montana. It is claimed that they will yield \$5 a day to the man.

GULCH mining is starting up quite lively in Montana.

The Hoosac smelting furnace is being put in repair for the summer campaign. When fully at work, seventy tons of ore will be reduced in twenty-four hours, and extra teams will be put on to haul the bullion to the railroad.

The Eberhardt mill, says the White Pine News, has been compelled to shut down, owing to the impossibility of getting ore down from the mine. The snow on part of the road is eighteen feet deep.

Those interested in Guerneville district, Sonoma county, think that the quicksilver mines discovered there will be as rich as those at Pine Flat.

JOHN R. TAYLOR has discovered rich specimens of cinnabar on Cache Creek, ten miles north of Bertlett Springs.

OVER 800 bars of bullion were brought into Los Angeles, one day last week, from the mining districts of the lower counties.

Metallurgy of Bismuth.

In reply to a correspondent's questions on this subject we insert the following paper, originally contributed to *Les Mondes* by M. A. Valenciennes, director of the factory of chemical and pharmaceutical products of the central pharmacy of France, at St. Denis.

It is well known that the bismuth of commerce has been for a long time extracted from the mines of Saxe, and that the preparation of this metal was very simple, as it was only necessary to heat the ore in melting-pots to separate the pure bismuth from its gangue.

The consumption of bismuth having increased of late years, the production of the mines of Saxe became at last insufficient, and the price in 1869 reached 55 fr. the kilogramme, while twenty years ago it hardly fetched 11 fr. Then there appeared in the market a new ore of bismuth, originally from South America, and rich enough to be brought to Europe, in spite of the expense of transport.

M. Dorvault, director of the central pharmacy of France, purchased in 1869 a considerable quantity of ore from Bolivia, and entrusted me with its metallurgical treatment in the factory of chemical and pharmaceutical products at Saint Denis.

This ore occurs in a vein of metal near the copper and silver mines situated in the chain of the Andes, close to the town of Azucar, in Bolivia. The proprietors of these mines have tried, but without success, to extract the bismuth upon the spot. The ore is brought on the backs of mules to the port of Cobija, whence it is embarked for England. It is composed of sulphide of bismuth mixed with sulphides of iron and of copper. Its gangue is mainly quartz; its richness in bismuth is very variable. In examining a medium sample coming from different lots, I have found the following proportions in a hundred parts:

Bismuth.....	22-30	30-05
Iron.....	16-20	16-90
Copper.....	9-50	12-15
Sulphur.....	19-50	16-90

Antimony, lead, and silver are also present in small quantities.

When the composition of this ore is compared with that of the samples described in treatises of mineralogy, a notable difference is observed. The latter come from the southern countries of Europe, and while they contain a great quantity of sulphide of lead mixed with sulphides of copper and of bismuth, or perhaps with sulphides of silver and of bismuth, that of Bolivia, on the contrary, contains but very little lead and silver, and a much greater proportion of sulphides of iron and copper. From the point of view of bismuth intended for pharmaceutical purposes, this composition is interesting, for the metal obtained contains but very little lead, the iron and copper, with sulphur, separating readily by the dry process, while the lead is very difficult to eliminate.

In order to avoid the transport of these rough ores to Europe with their gangue, an attempt was made to melt them in a blast furnace. Coal being scarce in those mountainous countries, the Indian miners employed a dried moss with a very thick and resinous root. They thus obtained some bismuth, and some matte formed of sulphides of bismuth, of iron and of copper; but they were obliged to abandon this procedure, because of the great loss of bismuth.

Among the samples brought by M. Dorvault, were some of the mattes resulting from these operations; but they did not contain upon the average more than 18 or 20 per cent. of bismuth.

Treatment of the Ore.

The ore, powdered, is roasted at a red heat for 24 hours in a reverberatory furnace, of which the bed is flat. A little coal dust is thrown in from time to time, and the mass is frequently stirred with iron rables. The ore, oxidized by this operation, is then mixed with three per cent. of coal, and a liquid composed of lime, soda and fluor spar. This mixture is introduced into a reverberatory furnace with a concave sole furnished with a tap-hole for running off the slag. At the commencement of the operation, the damper is shut in order that the reducing flame produced may assist the reaction of the coal upon the oxide of bismuth, and also to prevent the volatilization of that oxide. During the operation, which lasts for two hours, the mass is frequently stirred. The register is then opened, and the fire is urged to a white heat. At the end of two more hours, the mixture is perfectly liquid, and ready for drawing off into a casting-ladle lined with earth. On taking out the stopper the melted mass flows out, and the ladle is raised and left alone until the matter has become quite cold. There are found in the ladle three distinct layers which are divided according to their density. At the bottom, a layer of bismuth; above that, a matte composed of sulphides of bismuth and of copper; lastly, vitreous scoriae containing the iron from the ore in the state of silicate.

This bismuth, in a rough state, contains two per cent. of antimony and lead, and two per cent. of copper, besides a very slight portion of silver. When it is intended for the preparation of nitrate of bismuth, for use in pharmacy, it is only necessary to melt it to a red heat with some niter, in order to separate the antimony. The copper, lead and silver are eliminated by the wet process.

The matte drawn out from the top of the layer of bismuth contained, upon the average, from five to eight per cent. of bismuth. They were reduced to powder and calcined. The product of the calcination was afterwards smelted, the same result being obtained as in the first operation; the mattes from this second

fusion gave no more than one or two per cent. of bismuth. It was impracticable, by the dry method, to more effectually separate the bismuth, because it formed an alloy with the copper. In order to exhaust these last workings the wet process had to be employed.

Treatment of the Melted Ore.

This product, as we have said above, results from the first fusion of the ore, which separates it from the gangue. It is composed of the mixed sulphides of bismuth, of iron and of copper. We have treated it by two methods.

The first, a direct method, consisted in treating the pulverized substance by iron, without previous calcination. It was mixed with twelve per cent. of iron filings, twenty per cent. of vitreous scoriae, and a small quantity of soda. This mixture was put into the reverberatory furnace, and, after four hours' submission to a white heat, the whole was in full fusion. It was run off into a ladle, and after it had become cold there was found a layer of bismuth, a matte composed of sulphides of iron and of copper, and some vitreous scoriae. The bismuth thus obtained has less copper than that prepared by the previously described method, but it contained some antimony. This operation succeeded well, and was more expeditious than the first; but it had one considerable inconvenience, that the melted sulphide of iron attacked the sole of the furnace so strongly that it was impossible to continue the operation.

The first described method was therefore adopted. After the roasting, the ore, mixed with a flux, was carried to the smelting furnace. The flux employed was the same as that used for the natural ore, except that a little silicious sand was thrown in to replace the quartz of the gangue. The same results were obtained as in the treatment of the native ore.

It may be seen by the statement of these facts that the metallurgy of bismuth bears a certain analogy to that of lead, when the sulphide of bismuth from Bolivia is employed.

We have had occasion to examine a French ore containing some bismuth, at the same time that we were reducing the ore from America. This ore was found at Saint Angel, near Ussel, in the department of La Corrèze, and was sent to me by M. Jules Brougnart. It consisted of wolfram and oxide of bismuth.

After several ineffectual efforts to extract bismuth from this ore in the dry way, I had recourse to the following method: The ore was finely pulverized and digested, in two portions, with hydrochloric acid. The acid liquids were decanted, and one-half of the acid was neutralized by soda. Afterwards the solutions were poured into a large excess of water, when a precipitate of oxychloride of bismuth was found. This was washed, made into a paste with water, and left in contact with thin plates of iron. The bismuth thus reduced by cementation was dried and melted with an alkaline flux. This metal contained some traces of lead and silver.

The portion of ore insoluble in the hydrochloric acid was ignited at a red heat with nitrate of soda. The product exhausted by boiling water gave tungstate of soda.

Klamath County Mines.

The *Eureka Union* of the 25th publishes the following items from this out-of-the-way locality, of which the outer world has heard little or nothing during the past winter:

The Black Bear company are taking from their lower level rock of exceeding richness. Sometime back this company discharged several of their hands on account of running short of provisions to feed them. The stores in that section are out of sugar, out of candles, out of potatoes, and out of numerous other articles of prime necessity. A train of mules was expected at Sawyer's bar from Arcata about the time he left. As soon as the roads and trails are open, so that supplies can be shipped in freely, the Black Bear company will employ from 50 to 75 more men than they have at present, and a much larger force than they have ever employed before. The company have in contemplation to build a new mill the coming summer. The Klamath company are running a tunnel to strike the ledge at the lower level, and as soon as they strike it they will put on a largely increased force. There are yet on the mountain, between Etna and Sawyer's bar, about seven miles of snow—four on this side of the summit, and three on the other. This snow is of great depth, and will not disappear, if left to the slow process of melting, for weeks, and even months. The necessities of the people on Salmon, however, require that the trail should be open at an early day, as they are out of several of the necessities of life, which they are accustomed to get from Scott valley. To assist nature in the removal of the snow-blockade, they have taken up a subscription with which to hire a force of men to shovel the snow from the trail. In this movement they are joined by the people of Rough and Ready and vicinity. From what Father Callaban says, we judge it is much on the Salmon now as it was here in the starvation winter of 1852, "though with a variation;" there is there now money, money everywhere, but not a potato to eat; here there was money, money everywhere, and nothing but a potato to eat.

CHINAMEN are placer digging in the gulches of Greenhorn mountain. When you ask them how much they make a day, they invariably answer: "Sometime one bittee, sometime one dollar hop."—*Havilah Miner*.

Charcoal Coke for Smelting at Eureka.

In an article on the mines of Eureka district, question of fuel, etc., the *Eureka Sentinel* of a late date says:

The charcoal question is now being very extensively discussed, and should be, because it is one of no little interest to our citizens. The available fuel supply is every day becoming scantier and scantier under the increasing demands which our furnaces have each successive year made upon it. It is well known that charcoal is one of the chief agents employed to promote the prosperity of our camp, and anything that tends to both cheapen and increase its supply must be a matter of some concern to all interested. There is but very little wood of any sort available for coal to be met with on the hills within a radius of 25 miles of Eureka, and the area of the circle is every day rapidly extending itself. Coal or coke we must have, if we would continue smelting operations. Should the former give out, or the price per bushel advance to such a figure as would render it too dear for profitable use, it follows that the only substitute we can fall back upon to supply its place with any degree of profit to consumers, is the latter article. Cheap transportation is the great desideratum; upon it depends the future of the district, though there are some to be found in our midst, property owners, too, who are prone to think otherwise, and a railroad built upon any plan but their own, a useless and profitless undertaking. Such persons live but for the present. Progress and speculation are no parts of their creed. This class of persons not infrequently forget that the permanency and prosperity of a camp are often measured by the energy and enterprise of its population. Great natural resources, whether of the mineral or vegetable kingdom, will not, of themselves, do much good without they are utilized and made available for purposes of commerce and speculation. What benefit to the world or its commerce would the colossal wealth now lying within the confines of the Richmond, Eureka Consolidated and K K properties be, were it not brought forth from where for ages it has lain, to be disseminated among the people of the district?

The completion of the narrow-gauge, now in course of construction, upon which work was resumed on the 12th instant, will prove a certain and effective panacea for whatever difficulties may arise from a want of fuel. There were probably 360,000 bushels of charcoal on hand at the commencement of last season's operations. Are there as many now? No; nor are there likely to be for some months to come. The Consolidated may have 2,000 to 3,000 yet unused, while the past week has not given to the Richmond much above 12,000 bushels more, so that taking these two extremes and adding them will show us the small amount on hand as compared with last year. The amount that has been burned during the past winter is also very small. The severity of the weather retarded wood-chopping, pitting and burning. One hundred and seventy-five thousand bushels will cover about all that is now ready to be hauled. Let's see what the probable consumption would be for the next eight months, from May to January. Suppose eight of our furnaces should run for that period and were to consume daily for that time an average of 1,700 bushels each, we would require 13,600 bushels per day, 408,000 per month and 3,264,000 bushels for the eight months. But since there is no furnace will make a run of that duration, we must allow for stoppages, cleanings and repairing, say five days each or forty days altogether, in which 544,000 bushels would be consumed. Deducting this last sum from the former we will still leave a residue of 2,720,000 to be supplied during that period to meet the requirements of smelting. To produce this enormous amount among the hills will absorb for eight months the united labor of 5,440 men. The product of each man's labor for one month is generally estimated at 500 bushels. From this estimate we can see that it will take 680 men per month constantly employed to produce the 2,720,000 bushels that will be needed. Messrs. Reilly & Lockwood have not employed more than 108 men at coal burning the past winter, while Mr. Whisler did not work more than 80 men during the same period. These three men do not contemplate increasing their force more than 200 or nearly 400 altogether, which would leave the remaining 280 men required to be supplied by the remaining parties engaged in the business. With such a state of things staring us in the face how can it be expected that we can, with any degree of exactitude, judge of the amount of coal to be received this season?

Messrs. Reilly & Lockwood are about to inaugurate a new era in coal burning. They have already let their contract for the erection of several kilns wherein to burn coal, whose capacities are to be 50 cords each. They are to be built of stone and to be similar in construction to lime kilns, only that instead of being opened at the top similar to them, they are to have conical-shaped roofs with an aperture at one side, through which the wood will be put lengthwise into the kiln preparatory to burning. It is not claimed that this process will have any material influence in reducing the price, though it will give more and a better quality of coal than that produced by the old method of pit burning. The labor dispensed with in one department will be required in another; because it is manifest that the stationary character of the kilns will necessitate the wood being hauled from longer distances to them than was found to be needed under the old system.

Having pursued this vexed question so far,

it will be necessary, in order to do it justice, to present some pertinent facts in relation to the arguments adduced in favor of

Coke

As an article of fuel. The Dunderberg company has ordered 100 tons of this article, which it is in daily expectation of receiving from the West. That it will soon supersede charcoal in this camp, is among the certainties of the future, and this not so much on account of the price of the latter as from the increased scarcity of the wood from which it is produced. Should the charcoal rates advance within the next month or two, a crisis is imminent, for the mining superintendents are apparently not very willing to adapt themselves to the views expressed by our coal producers, and will, they say, should these views be put in practice, immediately order large supplies of coke from California and elsewhere. The Pancake article will soon be made available, too. Then much of the anxiety of smelters will be removed. Coke can be laid down here for present uses at \$60 per ton. One ton of it will reduce within a fraction of eight tons of ore, while the same quantity of the other, containing 125 bushels, at 16 pounds per bushel, will not smelt more than five tons. Coke, it is alleged, is, even with those equalities of results, cheaper than charcoal at 35 cents per bushel. The cost of 125 bushels of the latter at 30 cents per bushel is \$37.50, while the cost of the same weight of coke is 60 per cent. greater; but since it will smelt 60 per cent. more ore than the former, we find that it is fully as cheap as coal at the aforesaid rate. Now, from this showing, we can see that should charcoal advance to 35 cents, as it is claimed it will and must under the pressure of demand, seeing there is little or no coal on hand, the furnace men will be compelled to fall back upon coals entirely for smelting and other purposes. Should it, however, advance to only 32 cents, they will still demur, since they claim that an advance of six per cent. in the price would be even more than they could afford to pay; and if they cannot pay six per cent. they certainly will not pay 15 per cent., which an advance of five cents per bushel would make it.

Pioche Mines.

The *Pioche Record* of the 26th ult., says: Matters in our mines since our last report have been without any change of a character that calls for notice. There are about the same number of men at work in the respective mines, and about the same amount of ore being extracted. To the two great mining enterprises of the place, the Raymond & Ely and the Meadow Valley, these remarks are especially applicable. In others of lesser note there is perhaps more variation. The Silver Peak on Thursday struck a body of ore which looks as if it might prove to be of considerable value and extent. The Newark has acquired the title of the Amador Tunnel Company, including its mill. We understand the superintendent of the Newark intends to commence shipping ore in a few days. We learn that steps are being taken to pay off the incumbrances of the Caroline, and to resume work in a very short time.

While we were making our rounds yesterday collecting the data for our mining review we had the pleasure of meeting Col. W. H. Raymond, with whom we had a long conversation. In the course of our talk we naturally drifted into a discussion of the prospects of Pioche. The Colonel expressed himself very hopefully, and is evidently determined to fight it out on this line if it takes all summer, and the winter too, for the matter of that. Speaking of the present dullness of Pioche, Colonel Raymond reminded us that last year at this time not less than 200 tons of excellent ore were being extracted daily, and at present there are not probably more than 70 or 80 taken out of the ground, averaging one day with another.

The amount of bullion dispatched the past week by Wells, Fargo & Co. is \$65,667.21, and Pritchard's freight line \$7,239.30; total, \$82,906.51.

THE PROSPECTOR.—He leaves the haunts of civilization in early spring. The first bird who trills his notes (i. e. the bird that catches the worm), is anxiously looked for. His notes are a signal for new discoveries to be made and new districts to be formed. Mounted on a sorry broncho with long-eared burros packed with bacon, beans, flour, etc., with very few of the luxuries of life, plenty of ammunition and a trusty rifle, away he goes. Across torrents, without any bridges, and over mountains, without trails; traveling at night on the snow crust, paddling by day through the mire, goes the early prospector. Nothing stops him; he travels, eats, drinks and sleeps; but that is not all. Along the mountain sides he is constantly looking and watching for indications. No piece of rock, however small, and which differs in any way from the general country rock, escapes his notice. Should it be favorable for gold, it is soon prospected; if silver, he looks for more, and wending his way toward the source, finds more and more, till at last he is rewarded by finding the outcrop of the lode. Does he stop here? Not much. He looks for more lodes and finds them too, locates them, makes known his discoveries, names a district, immortalizes himself, owns plenty of mines, makes a sale, spends his greenbacks, gets up his broncho, packs his burros, goes for another discovery, and repeats this over and over, till he passes on to another world to—prospect. —*Colorado Express*.

Five Millions of Dollars for our Sugar Annually.

This is the amount of money paid annually for sugar entering the State through the port of San Francisco. The money for this sugar all goes to foreign countries, instead of remaining here as it might do, if our people had the will to inaugurate a beet sugar factory in one certain county in the State, and we mean Los Angeles county. We have just returned from a visit to that county, made for the express purpose of judging of the suitability of the lands there for the production of the sugar beet, and the facilities presenting for the successful prosecution of the beet sugar industry. We find in the valley of Los Angeles a tract of land so nearly limitless in extent, of such superior excellence for the growth of beets, so favorably situated for purposes of shipment of anything that may pertain to an establishment of the kind, their proximity to exhaustless beds of excellent peat, and mountains of asphalt available for fuel, the ease with which artesian water can be procured for factory purposes or irrigation, all point to the irresistible conclusion that it is the place where every pound and every dollar's worth of sugar needed for the supply of the entire Pacific coast of the United States can be easily and profitably produced.

The here inauguration of this industry upon a limited scale, anywhere within the broad sweep of that great and luxuriant valley, would at once add a ten-fold value to thousands of acres, and would alone amply reimburse the proprietors of the soil for making the necessary outlay. Appropriate a body of land to this purpose, reserving yet other acres by the thousands, to be eventually incorporated into one grand concern for the manufacture of beet sugar on a scale commensurate with its importance, and, under proper management, the same could be made so largely paying as to astonish even its most enthusiastic projectors and supporters.

Two crops of beets in a year from the same ground, the seeds for which can be planted with success every month of the year; no provision necessary to secure the winter's factory's supply of beets from frost, and the constant operation of the works during the whole year—instead of only six months, the extreme length of the sugar campaign in Europe—give to Los Angeles county advantages possessed by few, if any, and excelled by no other country in the world.

Wyoming Iron.

The following information is taken from the columns of the Nebraska Herald: By the courtesy of the general superintendent of the Union Pacific, Mr. T. E. Sickles, we had the pleasure of meeting Mr. Potts, a practical iron manufacturer of Pennsylvania, who has just returned from a visit to Wyoming, where he has been carefully examining the quality and quantity of iron ores in that territory, lying along the Union Pacific. We were pleased to hear from him that many of these ores, enough to operate a thousand furnaces, came under his own eye during a brief visit to that country, and that he has no doubt that these ores are equal to the best of those which have enriched Pennsylvania and the country. Fuller details are withheld by Mr. Potts, who is here as a representative of the Union Pacific, and who will report all the facts, together with his opinions of the practicability of iron manufacture in Wyoming to general superintendent Sickles.

Mr. Potts is a practical operator, and is here for the purpose of opening the way to the establishment of extensive rolling mills in Wyoming, for the Union Pacific company. He will be followed by experts who will trace and map out the veins of iron ore with their locality, that the railroad company may have complete data upon which to base their proposed operations. It is not doubted from what we have known heretofore about the intentions of the company that this visit of Mr. Potts is preliminary to the immediate construction of rolling mills in Wyoming, which are rendered necessary by the condition of the iron on the railroad, which must be re-rolled to save enormous outlays for the reconstruction of the track. Although this is now in good order, the necessity for new rails is foreseen, and must be provided for at an early day. An enterprise so important to the road and the country will be but the beginning of others, which will develop in the future great wealth in Wyoming, and which will give employment to large volumes of well paid, skilled labor.

A Good Binder for \$1.50.

Subscribers for this journal can obtain our Patent Elastic Newspaper File Holder and Binder for \$1.50—containing gilt title of the paper on the cover. It preserves the papers completely and in such shape that they may be quickly fastened and retained in book form at the end of the volume, and the binder (which is very durable) need continuously for subsequent volumes. Post paid, 25 cts. extra. It can be used for Harper's Weekly and other papers of similar size. If not entirely pleased, purchasers may return them within 30 days. Just the thing for libraries and reading rooms, and all who wish to file the Press. 1ambp

THE NEW U. S. MINING LAWS.

The new laws of 1873, governing the location and purchase of Placer and Quartz Mines, and Agricultural Lands in Mining Districts of the U. S., printed in circular sheet, for sale at this office. Single copies, 25 cts.

The Mining & Scientific Press.

Started in 1860, is one of the oldest weekly journals now published in San Francisco. It has been conducted by its present proprietors for ten years, during which period it has been repeatedly enlarged and constantly improved. The active and steadfast efforts of its publishers have gained for its conduct an amount of practical experience greater than any other publishers have accumulated on this coast, of a weekly journal.

The sum paid by us for the best editorial talent obtainable for our special class journal; for engravings, for interesting news and correspondence, and for printing a large-sized, handsome sheet, is unequalled by that of any other American weekly west of the Mississippi. As a PRACTICAL MINING JOURNAL it has no rival on this Continent.

It is the only MECHANICAL, and the only SCIENTIFIC Journal of the Pacific States.

Every Miner, Assayer, Millman, and Metallurgist in the United States should take it. Every Pacific Coast Mechanic, Engineer, Inventor, Manufacturer, Professional Man, and Progressive and Industrial Student should patronize its columns of fresh and valuable information. Every Mining Engineer, Superintendent, Metallurgist, Mine Owner and Mine Worker in the world should profit by its illustrations and descriptions of New Machinery, Processes, Discoveries and Record of Mining Events.

Every intelligent thinker in the land, in high or humble situation, who would avoid literary trash for genuine information, should SUBSCRIBE AT ONCE.

GRAND INDUSTRIAL EXHIBITION,

To be held under the auspices of the

MECHANICS' INSTITUTE

OF SAN FRANCISCO, CALIFORNIA.

Opening on August 18th, 1874.

The Board of Managers herewith announce that a grand Industrial Fair will be held in the city of San Francisco for 30 days, opening on August 18, 1874.

In view of the increasing commercial and manufacturing importance of San Francisco, its contiguity to and close connection with the various countries bordering on the Pacific, the managers have constructed a Pavilion having a floor area of 150,000 feet, and have invited to it all who are disposed to come and exhibit. All exhibitors will be placed on the same footing. Motive power will be furnished free.

The building will be open day and evening, and every facility will be extended to exhibitors and visitors.

Application for space must be made without delay to the Secretary of the Board of Managers, 27 Post street, San Francisco, and all inquiries will be answered and information extended promptly.

No space can be secured unless applied for before the 20th of July next. A. S. HALLIDIE, Pres. 13v28-3m

J. H. CULLIVER, Sec'y.

HEALD'S BUSINESS COLLEGE
BRYANT & STRATTON
24 POST ST. SAN FRANCISCO
FOR ALL TO ALL SEND FOR CIRCULARS

The object of this school is to impart a thorough education in business affairs. It is open to persons of both sexes and of all ages. There is an English Department for those not sufficiently advanced for the Business course. Sessions continue day and evening throughout the year. Students can enter at any time. All wishing to be successful should secure a practical education at this College. Send for "Herald's College Journal," and learn full particulars. Sent free to all by addressing E. P. HEALD, Pres. Business College, San Francisco, Cal. 2v27-1y

Capital required: Nerve and Honest Industry

THE FAR WEST,

The Great Treasure Chamber of America.

All about its Resources, Mines, Railroads, Lands, Indians,

Climate, and Developments Illustrated and Described in

Placer Mining Land for Sale.

In many of the States of the U. S. of Colombia immense banks of auriferous gravel exist, which wait only for capital to be developed into rich paying properties. The gravel banks are similar to those of California. Several companies are now operating there with success, and there is plenty of room for others. The owners of these lands are anxious to sell or lease to capitalists, or are willing that experienced California gravel miners should work them on shares. Water and timber abound in the localities of the mines. The interior of the country is healthy, and the elevation is such, that the climate is excellent. Mr. Ricardo Morales, Colombian Consul in this city, is empowered to negotiate for the sale or lease of different tracts of land in the State of Cauca on very easy terms and liberal conditions. The lands may be obtained for trial for a number of months, in order that purchasers may know what they are trying. At the office of Mr. Morales, No. 710 Washington street, in this city, may be seen different samples of gravel, cement and gold from these mines, with maps of the country and the tracts of mining ground. He will be glad to furnish any information desired by those who intend going to these new mines, either by letter or personal interview. Mr. A. C. Fernandez, who has just returned from these mines, may also be seen at the same office.

SCIENTIFIC PRESS.—The attention of our readers is called to an interesting article on the Mining Industry of Northern Sierra, on the first page of this issue, from the SCIENTIFIC PRESS, San Francisco. This is the ablest, most instructive and influential Mining Journal published in the Great West, and should be liberally patronized by all our mining friends.—*Mountain Messenger*, April 25.

GENUINE CHESTER EMERY.

REDUCTION IN PRICE.—The great in-
crease in the production of the Chester
Emery Mine enables us to reduce the price
to seven cents for grain and four cents for
flour, with important discounts to dealers, manufac-
turers and larger purchasers. The genuine Chester
Emery is made from the purest and hardest crystals,
and its cutting and polishing qualities are superior to
any emery used in this market.

Francisco, Cal.

POSTPONEMENT.—The above sale is postponed
until Monday, the 18th day of May, 1874, at the hour of
12 o'clock m., at the office of said Company, Room No.
7, No. 401 California street, San Francisco, Cal. By
order of the Board of Directors.

Office—Room No. 7, No. 401 California street, San
Francisco, Cal.

Continental Silver Mining Company—Loca-
tion of principal place of business, San Francisco,
State of California. Location of works, near Treasure
City, White Pine County, Nevada.

NOTICE is hereby given, that at a meeting of the Directors,
held on the 4th day of May, 1874, an assessment (No. 4)
of the capital stock of the corporation, payable immediately
in United States gold coin, to the Secretary, at the office of the Company, 118
Front street, San Francisco, California.

Any stock upon which this assessment shall remain un-
paid on the 7th day of June, 1874, will be delinquent, and
advertised for sale at public auction, and unless payment is
made before, will be sold on Tuesday, the 29th day of
June, 1874, to pay the delinquent assessment, together with
costs of advertising and expenses of sale.

THEODORE BLANKENBURG, Secretary.
Office, 118 and 120 Front street, San Francisco, California.

Diamond Silver Mining Company.—Loca-
tion of works, East Tintic Mining District, Juab
County, Utah Territory. Principal place of business,
San Francisco.

NOTICE is hereby given that at a meeting of the Board of
Directors, held on the 18th day of April, 1874, an assess-
ment, No. 1, of ten (10) cents per share was levied upon the
capital stock of the corporation, payable immediately in
United States gold coin, to the Treasurer, J. F. Fish, at the
office of the Company, No. 123 Post street, San Francisco,
California.

Any stock upon which this assessment shall remain un-
paid on the 1st day of June, 1874, will be delinquent,
and advertised for sale at public auction, and unless pay-
ment is made before, will be sold on Thursday, the 26th day
of June, 1874, to pay the delinquent assessment, together
with costs of advertising and expenses of sale.

Office—No. 123 Post street, San Francisco, Cal.

Geneva Consolidated Silver Mining Compa-
ny.—Principal place of business, City and County of
San Francisco, State of California. Location of works,
Copper Creek Mining District, White Pine County, State
of Nevada.

NOTICE is hereby given, that at a meeting of the Board of
Directors, held on the second day of May, 1874, an assess-
ment of twenty-five (25) cents per share was levied upon
the capital stock of the corporation, payable immediately
in United States gold coin, to the Secretary, at the office

of the company, Room 14, No. 302 Montgomery street, San
Francisco, California.

Any stock upon which this assessment shall remain un-
paid on the eighth (8th) day of June, 1874, will be delin-
quent, and advertised for sale at public auction, and unless
payment is made before, will be sold on Monday, the
twenty-ninth (29th) day of June, 1874, to pay the delin-
quent assessment, together with costs of advertising and
expenses of sale.

Office, Room 14, 302 Montgomery street, San Francisco,
Cal.

Jefferson Gold and Silver Mining Com-
pany. Location of principal place of business, San Fran-
cisco, Cal. Location of works, Brown's Valley, Yuba
county, California.

NOTICE.—There are delinquent upon the following
described stock, on account of assessment (No. 2) levied
on the 26th day of March, 1874, the several amounts
set opposite the names of the respective shareholders
as follows:

And in accordance with law, and an order of the
Board of Directors, made on the 25th day of March,
1874, so many shares of each parcel of said stock as may
be necessary, will be sold at public auction, at the office
of the Company, Nos. 214 and 215 Pine street, San Fran-
cisco, Cal., on the first day of June, 1874, at the
hour of 12 o'clock m., of said day, to pay said delinquent
assessment thereon, together with costs of advertising
and expenses of sale.

Office—No. 214 and 215 Pine street, San Francisco, Cal.

Land Purchasers' Association—Office, No.
425 Kearny street, San Francisco, Cal.

NOTICE is hereby given, that at a meeting of the Directors
or Trustees of this corporation, held on the 14th day of
April, 1874, an assessment of ten dollars per share (being
the 40th monthly installment on the subscription to the
stock) was levied upon the capital stock of said corpora-
tion, payable immediately, in United States gold coin, to
the Secretary, at No. 425 Kearny street, San Francisco,
California.

Any stock upon which this assessment shall remain un-
paid on the 18th day of May, 1874, will be delinquent, and
advertised for sale at public auction, and unless payment is
made before, will be sold on the 30th day of June, 1874,
to pay the delinquent assessment, together with costs of
advertising and expenses of sale.

Office, No. 425 Kearny street, Room No. 2, San Fran-
cisco, California.

N. B. This assessment is levied to pay the balance due
for grading Washington street.

Mansfield Gold Mining Company.—Loca-
tion of principal place of business, San Francisco,
California.

CAST STEEL SHOE AND DIE COMPANY,

OFFICE—Room 28, Hayward's Building, 419 California St., S. F.

Patented CAST STEEL SHOES & DIES for Quartz Mills.

Price, 20 cents per Pound.

CAST STEEL DIE.

CAST STEEL SHOE.

An improvement greatly needed—being Stronger, more Durable and Economical than Cast Iron; as the Dies, when worn down, can be welded to the Shoes as easily as bar steel; never break; keep their full striking surface. Battery of five shoes crushes one-ton more ore in 24 hours than Cast Iron Shoes, will wear as long as four sets of Cast Iron Shoes, and can be worn down to 1/2 inch in thickness. The studs can be welded into Picks, Hammers, etc.

—ALSO—
Cast-Steel Tappets, Cams, Hammers, Gearing and Castings
OF ALL KINDS, A SPECIALTY.
It takes forty days to fill orders.

CALIFORNIA BRASS FOUNDRY,

No. 125 First street, opposite Minna, SAN FRANCISCO.

ALL KINDS OF Brass, Composition Zinc, and Babbitt Metal Castings, Brass Ship Work of all kinds, Spikes, Sheathing Nails, Rudder Braces, Hinges, Ship and Steamboat Belts and Gongs of superior tone. All kinds of Cocks and Valves, Hydraulic Pipes and Nozzles, and Hose Couplings and Connections of all sizes and patterns, furnished with dispatch.

PRICES MODERATE.

Machinery.

TREADWELL & CO.'S

UPRIGHT SAFETY ENGINES,

2 to 10 Horse Power.

MADE BY THE N. Y. SAFETY STEAM POWER CO.

Has tubular boiler, and therefore is secure against the dangers common to shell boilers. Power is taken from near the base, which avoids vibration or top-heaviness. Occupies but two feet square of floor space and is so simple a boy can run it. All its parts are easily accessible—a great advantage. Is complete in itself as a Portable Engine and Boiler, or the engine can be detached from the boiler and run independently, if required. Its main points are SIMPLICITY, SAFETY and ECONOMY. For printing offices, laundries, tanneries, ranches, small repair and machine shops, or for boistering wherever a small and safe power is required, they are peculiarly adapted.

Refer to the following parties who have them in use

E. DETTRICH & CO., Bag Factory, San Francisco;
PACIFIC CHEMICAL WORKS, San Francisco;
ST. IGNATIUS COLLEGE, San Francisco;
STEAMER "PELICAN";
STEAMER "COQUILLE";

CROCKER'S PATENT TRIP HAMMER QUARTZ BATTERY.

This machine, complete, weighs 1,500 lbs. Has an iron frame, two steel arms with stamps weighing 17 lbs. each, which strike 20-60 blows per minute, in a mortar provided with screens on both sides, and crushes FINE 600 lbs. per hour, requiring one-horse power to drive it. Has been thoroughly tested, and is guaranteed to give good satisfaction. PRICE, \$600.

G. D. CROCKER,
17v26-4f 315 California street, San Francisco.

TO HYDRAULIC MINERS.

I warn Hydraulic Miners not to be misled by the advertisement of Mr. F. H. Fisher. Said Fisher has been beaten in every suit to which he has been a party (respecting Patent Rights on Hydraulic Machines), whether as plaintiff or defendant.

His patrons have already paid over Five Thousand Dollars for license to use machines purchased of the self styled

"Only Reliable Party in the Business Who Protects His Customers."

Fisher's Machine is worthless unless the discharge pipe is furnished with appliances, the patent for which is owned by Messrs. CRAIG, and which Fisher is enjoined from making.

The Machine itself is also an infringement on another patent owned by the same parties.

All persons infringing on either of these patents

WILL BE PROMPTLY PROSECUTED.

I am sole LICENSEE to sell Machines manufactured under Craig's, Rice's, Macey's and Hoskin's patents.

I Guarantee Full Indemnity to all my Customers.

Machines of all sizes always on hand.

If you want a Machine that will give satisfaction, and do not want to pay for it twice over, buy an Improved LITTLE GIANT.

ASSAYERS' MATERIALS
—AND—
Chemical Apparatus,
Having been engaged in furnishing these supplies since the first discovery of mines on the Pacific Coast.
Our Gold and Silver Tables, showing the value per ounce, Troy at different degrees of fineness, and valuable tables for computation of assays in Orais Grammes, will be sent free upon application.
7v25-4f **JOHN TAYLOR & CO.**

CALIFORNIA Quartz Crushing & Ore Sampling MILLS.

Nos. 413 & 415 Mission st., bet. First & Fremont, S. F. public.

Ours is the OLDEST, LARGEST and MOST EXTENSIVELY KNOWN establishment of this kind on the Coast.

Our mills are under the direct supervision of one of the most experienced Samplers and Millmen in the country, and we purpose carrying on the business upon a scale commensurate with the wants of the mining public.

We have the best facilities for Crushing, Sampling and Pulverizing all classes of Gold, Silver, Copper and Lead Ores and other minerals.

We also crush and pulverize all kinds of Marble, Fire-Clay, Bricks, Coke, Cement, etc., upon the shortest notice, for which we have special mills.

Reliable information furnished to miners and ore dealers concerning shipping rates, water prices, etc. Prompt execution of all orders. Faithful attention to business entrusted to us.

Abundant storage room without extra charge.

Ja31-4f "JIM" WHITLATCH, Sup't.

E. N. RIOTTE, JAS. L. BEYER, S. O. BROWN.

AUBURN MILL COMPANY, Reno, Nevada.

Purchase Silver Ores in quantities of ten tons and upwards, delivered on board the cars at San Francisco or Oakland and at the annexed Net Rates, with no charge for SAMPLING OR REDUCTION. On lots of less than 10 tons, freight to Reno will be deducted.

Special Rates for Gold Ores.

On Gold contained in Silver Ores to the amount of \$30 and upwards, 63 per cent. will be paid. When less than \$30, and above \$10, the amount will be added to the Silver value. Sacks promptly returned free of charge. Ores sampled by Battery or Sampling Mill as shipped may elect, and returns made promptly by cheque on San Francisco.

Varney's Patent Amalgamator.

These Machines Stand Unrivaled.

For rapidly pulverizing and amalgamating ores, they have no equal. No effort has been, or will be spared to have them constructed in the most perfect manner and of the great number now in operation, not one has ever required repairs. The constant and increasing demand for them is sufficient evidence of their merits.

They are constructed so as to apply steam directly into the pulp, or with steam bottoms, as desired.

This Amalgamator Operates as Follows.

The pan being filled, the motion of the muller forces the pulp to the center, where it is drawn down through the aperture and between the grinding surfaces. Thence it is thrown to the periphery into the quicksilver. The curved plates again draw it to the center, where it passes down, and to the circumference as before. Thus it is constantly passing a regular flow between the grinding surfaces and into the quicksilver, until the ore is reduced to an impalpable powder, and the metal amalgamated.

Settlers made on the same principle excel all others. They bring the pulp so constantly and perfectly in contact with quicksilver, that the particles are rapidly and completely absorbed.

Mill-men are invited to examine these pans and settlers for themselves, at the office, 229 Fremont Street, San Francisco.

Morris' Settler and Amalgamator.

PATENTED MARCH 25, 1873.

An important improvement in milling. Cheap, light, efficient and durable. Gains Quicksilver on working tailings. Is discharged from the surface in the center instead of the side, by means of a Siphon which extends to near the center of the Settler. Heaviest casting weighs only 135 pounds. The sides and bottom of the Settler are made of wood, as also Mullers, placed vertically—the friction of which brightens the quicksilver. One of these machines is in daily operation at No. 616 Merchant street, (basement) San Francisco. Parties desiring information as to rights of use, purchase, etc., can address,

OF SUPERIOR QUALITY, FRESH FROM THE MILLS. It being constantly received and transported into the interior, is delivered to the consumer within a few days of the time of its manufacture, and is in every way superior to any other Powder in Market.

We have been awarded successively

Three Gold Medals

By the MECHANICS' INSTITUTE and the STATE AGRICULTURAL SOCIETY for the superiority of our products over all others.

HERCULES POWDER.

We wish to call the attention of miners and others of our readers to a few points of superiority of the HERCULES POWDER over all other strong explosives.

First—Its strength is greater than that of any other in use. The materials of which it consists are compounded upon strictly scientific principles, and not a simple neutral absorbent employed that will hold a quantity of nitro-glycerine. It is the opinion of the best chemists to whom the matter has been submitted, that no mixture has been employed that so thoroughly promotes the whole tremendous force of the explosives employed, and at the same time neutralizes the offensive gases caused by the explosion. With this Powder one half the time is saved that is lost by using any other strong powder, before you can resume work after a blast.

Second—UNIFORMITY.—The materials of the mixture are chemically prepared, and therefore greater uniformity can always be depended upon and the best results attained. This is a great advantage over any that varies in its strength, as those must which are mixed with any natural earth.

Third—SAFETY.—So perfect is this mixture that no accident can happen with it from premature or accidental explosion, if persons will half follow the rules laid down for its use. No powder has ever been invented where so few accidents have happened with it in proportion to the quantities which have been used.

Fourth—CARTRIDGES.—It is well known that nitro-glycerine has a tendency to decompose by volatilization. These are the "fumes" that are smelled on going into a mine or room where nitro-glycerine powders are stored. To prevent the escape of these "fumes" an almost hermetically sealed cartridge is employed, and so effectual is it that some cartridges filled with Hercules were exposed to a blazing California sun for six months last summer, with no perceptible loss of strength. This is a great advantage over the open paper usually used for cartridges.

Fifth—ECONOMY.—We believe that any miner who will take the trouble to investigate the matter will satisfy himself that full fifteen per cent. is saved by using the Hercules over any other strong powder manufactured.

QUERY—IS THIS WORTH SAVING? WE SHOULD THINK SO. TRY IT.

Sold by the CALIFORNIA POWDER WORKS, 314 California Street, San Francisco, Cal. Also, all grades of Black Powder, Fuse, Shot, Caps, etc.

VOLUME XXVIII
Number 20.

Prevention of Overwinding at Hoisting Works.

We present to our mining readers this week diagrams of an improved detaching hook, lately described in the London *Mining Journal*; and which has been successfully tested at one of the large collieries in England. It is the invention of Mr. W. Walker, M. E., of Silthurnby-the-Sea, England.

The improvement consists in so attaching the cargo or load to the lower end of the hook that when the pins are cut the weight of the load itself assists to take hold more rapidly. The principle of the invention has frequently been described as being admirably simple, and Mr. Walker claims that with this modification he has made it so perfectly adapted to this end he has in view that where it is used overwinding is rendered impossible, and perfect safety is obtained from this fact that if the load be raised above a certain point this weight of the load compels the rope to become detached, which detaching cannot take place until the jaw hooks have a firm hold on the supporting ring. It is remarked that the apparatus can be easily applied to every rope permanently raising or lowering a load, whether loose or secured in its traveling position by skeels or guides, and particular attention is drawn to the twofold cause of safety found in this hook. Supposing what is a practical impossibility, that the load did not force open the jaws, the bottom flange of the ring would press the clamp against the incline of the lower limbs, thereby causing the jaws to open and the jaw hooks to act.

In the above diagrams Fig. 1 is a front view of the hook, Fig. 2 an edge view, and Fig. 3 a front view of the whole apparatus, with the supporting ring and clamp in section, showing the hook just after the liberation of the lifting rope. The same letters refer to the same parts in both figures.

The lifting rope is attached to the shackle, A, and the load to the connecting link, B. The supporting ring, C (through which the rope is constantly working), is a fixture in a bulk of timber, or iron girder, at this pit top. The hook consists of a pair of jaws, D, D, working on a center pin, E, in such a manner that the weight of the load has a tendency to open the upper limbs, which clip the strong center pin of the shackle, A. The upper limbs are formed externally with jaw hooks, F, F. The jaws are kept together, and made to retain the shackle pin by means of this clamp, H, which is held in position by the pins, I, I. In case of overwinding, the jaw hooks (held together by the clamp) pass freely into the ring, C, but the projections, K, K, of the clamp coming into contact with the bottom flange of the said ring hold the clamp stationary, while the jaws are being pulled through, the result being that the pins, I, I, are sheared off, and the jaw hooks released from the restraint of the clamp. The internal diameter of this ring being the same as the width across the jaw hooks, F, F, the rope remains secure, until the jaw hooks reach the top of the ring, when, by the action of this weight of the load, they are forced open, and so hook on to the top of the supporting ring, C, as shown in Fig. 4, the rope passing harmlessly over the pulley. The recess, O, in the ring, C, is intended to meet an imaginary case that experiment shows to be almost impossible—that if the engine is reversed after the pins, I, I, are cut, and before the hooks reach the top of this ring, the jaws will then hook into the recess, and the load remain suspended in perfect safety. It will be observed that the upper edge of this ring, C, is curved to match the sweep of the jaw hooks when opening. By this arrangement all shock is avoided.

It is a great advantage with hooks of this class that they can be almost instantly re-adjusted after the occurrence of an accident, neither rope nor cage being injured by the overwind. Although increased care on the part of the engineer will, doubtless, do much to diminish the number of accidents from overwinding, the present invention appears to be well worthy of general adoption, since it is one of those which it is not likely to tend to cause carelessness, as by the use of a suitable seal on the soft pins every case of overwinding could be readily detected, and adequately punished by fine or other-

wise, whilst neglect would not be attended, as at present, by loss of life. The invention displays ingenuity, and appears likely to give satisfaction.

Kitts' Improved Header Beam.

To harvest the extensive grain fields, which are so characteristic of California, farming,

them horizontally into it, or secured upon it across its upper face and held down by an iron plate.

Mr. Kitts constructs the beam quite narrow and of considerable depth. To secure the necessary amount of rigidity he secures a flat iron bar or plate, C, along the front of the beam. He secures the guards in the beam by bending their rear ends at a right angle to the forward part, so that the bent portion can be driven

DEVICE FOR PREVENTING OVERWINDING.

requires quick work; and quick work is always accompanied with a certain amount of carelessness. This carelessness, in connection with the faulty construction of harvesting machinery,

down into the beam from the top and thus lost the guard and end extend out in front of the beam. The beam and plate are notched opposite each guard, so that when the guard is driven down into the groove or notch, its upper

KITTS' IMPROVED HEADER BEAM.

occasions great waste. It has been stated that enough grain is wasted in a single season to pay for harvesting the entire crop. One of the most serious causes of this waste is the falling of the heads of grain in front of the header after they have been cut by the sickle, owing to the angle at which the sickle and beam must work, especially in short grain. Numerous devices have been resorted to in order to ensure the lodgment of the cut grain upon the draper. Our illustration represents one of these devices, which was recently patented through the Mining and Scientific Press Patent Agency, by Philander Kitts, of Monticello, Napa county, in this State. The sickle beam, A, of a header is ordinarily made of considerable width and depth in order to secure a proper amount of stiffness or rigidity, and also to permit of the guard fingers being secured in it by driving

side will be even with the upper surfaces of the beam.

At the rear of the beam, A, he secures a double angle plate, D, so as to form a sort of trough within which the edge of the draper or carrying belt runs and is guided. This plate is secured so that its upper bend is a little below the upper edge of the beam, A, and as the beam is very narrow the sickle, E, beam A, and plate, D, will form narrow steps down which the cut grain and heads will fall easily upon the carrying belt, and there will be but little danger of waste or clogging, because of the nearness of the belt to the knives or sickle.

The ore stops in the east vein on the 1,400-ft. level of the Crown Point mine, are opening up splendidly, the ore being of a fine quality and the ore body of much greater width than it was on either of the levels above.

Work on Tunnel Locations.

An amendment to the Mining Law of May 10th, 1872, has been introduced in Congress, which provides that work done on a tunnel for the purpose of tapping a ledge shall be equivalent to work done upon the ledge. The Commissioner of the Land Office decided in August, 1872, that the expenditures in running a mining tunnel, before a lode was struck therein, were not tantamount to expenditures on the lode.

This construction of the law was approved by the Acting Secretary of the Interior, and accordingly, if work was not done on the claims themselves, in addition to work on the tunnel, the claims were subject to relocation as required by law. This amendment to the Mining Law of May 10th, 1872, changing the law in respect to work done on tunnels, and which is now under consideration in Congress, is as follows:

A BILL to amend the Act entitled "An Act to promote the development of the mining resources of the United States," approved May tenth, eighteen hundred and seventy-two.

Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled, That the fifth section of said Act be, and the same is hereby amended so that where a person or company shall run a tunnel for the purpose of developing a lode or lodes, owned by said person or company, the money so expended in said tunnel shall be taken and considered as expended on said lode or lodes, whether located prior to or since the passage of said Act; and such person or company shall not be required to perform work on the surface of said lode or lodes in order to hold the same as required by said Act.

CLAYTON'S MILL.—Our correspondent, I. P. Mc., informs us that this mill, which has 37 stamps, seven pans and is 60x125, containing the hoisting works for the American Flag mine, is one of the best arranged mills in Colorado Territory. An engine of 35-horse power is used in running the stamps, pans and hoisting machinery. This mill has been running almost constantly for the last three years and has crushed over 2,500 cords of quartz, most of which was onstom work. It will soon be run on the ore from the American Flag mine, which is connected with the mill by tramway, by which the ore is dumped in this battery room at comparatively little expense. The American Flag mine or the principal part of what is now being worked is owned by J. W. O. Clayton, proprietor of Clayton's mills, and as far as developed shows a fine body of ore. The main shaft is down 175 feet, from which two levels have been run west 150 feet, most of which is in excellent pay. Ore from this mine has run on an average about 8 ounces per cord, and can be broken, hoisted and milled at an expense of \$35 per cord. At present there are on the dump outside the mill about 150 cords of ore, besides perhaps 60 cords broken in the mine.

NEW MONTANA MINES.—We see by the *Montana Independent* that good mines have been recently found within one mile and a quarter from the mouth of Bear. The Dean brothers sunk a shaft to the depth of fifty-two feet and took out \$17 from the bottom of this shaft. They have since taken out as high as \$54 from a five-foot set of timbers. This new discovery will encourage the working of from ten to fifteen new claims, some of which will soon be proved, as the surface clay is of such consistency as to prevent the water from sinking to the bed rock.

NAILEIGH MINING DISTRICT.—This new district on West Walker river was formally organized last month. It is bounded as follows: Commencing at the Garrad Smelting Works, on Walker river, and running thence up the west branch of Walker river to a point opposite the mouth of Alkali valley; thence up Alkali valley to Spring gulch; thence to Churchill canon to the Wadsworth and Mason valley road; thence following the Mason valley road to the beginning.

THE Birmingham Iron Works of Connecticut have concluded a contract with the Union Pacific Railroad Company for the construction of rolling mills to be erected west of the Rocky mountains on the Pacific slope.

CORRESPONDENCE.

Mining in Plumas and Sierra Counties, No. 6.

[By our special correspondent.]

ERRORS PRESS.—Owing to being absent from this section of country some time past I have been unable to furnish you with my letters as usual. There will, I hope, be nothing to prevent your receiving them regularly in the future, until the series is complete.

Southeast from St Louis on the Slate creek side is the eastern channel of the

Great State Creek Basin,

The Star company tunnel, under the able management of Evan Jones, Esq., are at work in front, or what is sometimes called braw ground, and have as yet been unable to reach the deeper main channel, which winds along under the dividing ridge of Slate and Cañon creeks, being here over one mile in width. There is no doubt of the great wealth of this channel, whose treasure vaults must yield to the sturdy miner their golden wealth.

North of the Star company are the

Clipper Ship and Jenny Lind Companies,

Whose ground is lying at present dormant, on account of several owners in the same having become scattered throughout different parts of the country, their place of residence being unknown to the present occupants, who intend opening out the mines again, under the United States laws of May 10th, 1872, and to apply for a United States Patent to the same. Southeast of the Star is

The Caledonia Company,

In Cedar Grove district, owned by a body of men who are all company, and consequently are not working their mine with that energy with which it should be prosecuted, and would be if owned by capitalists. It is claimed they average less than seven hours per man each day, and still they realize large pay. This company is composed of twelve shareholders, and there are not over nine men working at a time on an average; still, with this number of men, they obtain from \$20,000 to \$35,000 per year. Adjoining the Caledonia company are the extensive claims of the

Excelsior Company,

Owned by Messrs. McCrory, Hendel and Small, formerly belonging to Deacon Long, who worked off a small part of the front ground by hydraulic process, in its primitive state, realizing over \$6,000 from but a small piece of ground worked. Here he lost the bedrock, and subsequently became deranged and committed suicide; his mine passing into the hands of the present owners. Immediately northwest of the Excelsior claims, the ground having all been front ground, has been worked in early days by many small companies, who have all taken over large fortunes. I am informed by Mr. McCrory, who owned 2½ claims (100 feet square constitutes a claim in this mining district), that in two years they took out the sum of nearly \$75,000 after building an expensive tunnel which cost \$30,000, and which I now understand is owned by Col. Baker, who also owns some mining ground immediately adjoining this worked out ground, and that of the Excelsior company, which is all piling ground and no doubt will pay well when the Gardner's Point and Grass Flat property has been worked out, which I fully believe will not occur during the present century. Southwest of Cedar Grove the channel is again extensively operated in the adjoining

Grass Flat District.

At Gardner's Point the first company we come to is the Comet & Challenge Consolidated Company, who own some 2,000 feet of front, extending back into the hill and containing from 200 to 300 acres of valuable mining land, the richness of which has been fully proven. Although for want of capital and a sluice tunnel the present owners are drifting in front ground and working under many disadvantages, they are working ground that pays them \$20 to one set of timbers in the main tunnel, 4½ feet apart, 6 feet high, and averaging 4½ feet wide. Yet the greater and richer portion of this mine is best adapted for hydraulic purposes, but as I said before needs capital. From my personal acquaintance many years ago with the late Col. Johnson—at one time a heavy owner in the Comet ground—I know that this company drifted from a small section of ground nearly \$150,000. But as the shareholders of the mine were not practical miners they worked the mine to a great disadvantage without surveys or system. The mine was allowed to cave in and lay idle for many years, until the present owners purchased, and are working it as above stated, having ground that is without a doubt richer than that of the far famed Cherokee mine, which produces over \$40,000 per month. Southwest of the Comet and Challenge Consolidated Company—now known as the Treasure ground—is situated the well known and immensely rich ground of the

Gardner's Point Property,

Now known as Col. Baker's claims, where any of your many readers can at any time be accommodated with a prospect which they would feel delicate in taking along with them on account of its great quantity of beautiful golden ore. It is not uncommon to see prospects of from \$5.00 to \$8.00 per pan of dirt taken from

next the bedrock or from 10 to 25 cts. 20 to 40 feet above the bedrock. From good authority I am lately informed that from one pan of gravel near bedrock and on the rim-rock \$150 were taken. The gravel banks of this mine are this year of a heavier quartz gravel and of deeper dark blue color. The banks are crumbled down by two little giants with an immense pressure of water. Everything is well fitted up and move along like clock work under the able management of Col. Baker and his assistant, D. E. Stover. This is the pioneer mine this year in commencing piling in northern Sierra, or southern Plumas counties. Their flumes end undercurrents, are all of the latest and most approved plan now in vogue; and it is presumed that not less than from \$75,000 to \$100,000 will be the net profits of this claim. The pay of the past washings averaged over \$100 per cubic yard and is now no doubt of a richer nature, as work is fast progressing toward the main channel. South of Gardner's Point and adjoining is the Rifle company, who have run a bed rock tunnel for drifting purposes from Grass Flat Ravine; but the owners not having coin sufficient to prosecute their work this mine lies dormant at present. Next comes the well known

Pioneer Gold Mining Company,

Containing some 360 acres of ground to which they have obtained quite recently a United States patent, their mineral location covering the whole of this immense channel passing through Grass Flat, proper, where the same is, perhaps, wider than at any other point, with the exception, it may be, of near Mount Pleasant ranch. In Grass Flat the channel is about 1¼ miles in width, and its rich gravel banks are many hundreds of feet in depth.

The company (a consolidation of several mines) have been at work on their present (lower) tunnel for over 10 years, which is in some 3,500 feet, besides a branch tunnel several hundred feet in length. Their present tunnel has been driven too high to work the deeper part of this great channel by drifting, and has not fallen enough to work any portion by hydraulizing. This company has spent not less than \$60,000 in prospecting their ground, but it is now beyond any doubt a well known fact that they possess one of the richest, largest, and best prospected hydraulic gravel mines in the State.

Just think of a mine covering 360 acres of mineral ground with a tunnel 3,500 feet run under it lengthwise, 3,000 feet of which has all been run in gravel, most of it over 20 feet above bed rock, that has yielded on an average \$1.32 per cubic yard and by the many shafts raised by the company, and the many shafts sunk by adjoining companies, all of them in gravel throughout which color has been obtained from top to bottom, and you will be able to form something like a correct idea of the immense number of tons of gold slumbering in this immense basin.

Laporte, May 1st, 1874.

Notes of Travel in Colorado.

[By our Traveling Correspondent.]

Bobtail Tunnel.

In continuing my letter of last week the first enterprise I shall mention is the Bobtail Tunnel Company, which is an incorporation of \$100,000, capital stock. A. N. Rogers is President and Superintendent, and H. Messenger Secretary. The principal office is at 25 Nassau street, New York City. John Stanton, Jr., of New York City, is the Treasurer. This company's works, tunnel and mine, are located at the lower end of Central City, Colorado Territory. The company was formed to tunnel Bobtail hill in a southerly direction, to cut the different ore bodies of said hill at right angles at a depth sufficient to drain them of water and give them an outlet for their ore without hoisting. But it was especially run to tap the Bobtail mine. This tunnel is now in 1,150 feet to where it intersects the vein of the Bobtail mine. At a distance of 570 feet from the mouth this tunnel cuts the Fisk lode, which is now being worked through the tunnel. The tunnel itself is 6x7 feet in the clear, and was originally intended for a double track, but has only a single track for ore cars; it was begun in the year 1863, by the original company, but was not completed until about February 1st, 1873, being abandoned for nearly one year during that time. It is estimated to have cost \$50,000 so far as the Bobtail lode (1,150 feet).

The Consolidated Bobtail G. M. Co.

Was incorporated with a capital stock of \$1,053,000. Geo. A. Hoyt is President, John Stanton, Jr., is Secretary and Treasurer, and A. N. Rogers is Supt. The company have run west on their ore body 500 feet, and for a distance of 250 feet east, and have developed the mine at one point 60 feet below the tunnel. The ore body in this mine runs from 3 to 10 feet wide, over one-half of which is milling ore, running from \$5 to \$300 per ton in gold. Of the whole amount of ore they extract, about 6 per cent. is smelting ore, and this carries some six ounces of silver to the ton. At the present writing they are working some 30 men in their mine, and extracting about 18 tons of all grades of ore daily. This mine is opened so that they are enabled to work a force of 150 men, but they are keeping back their workings for reasons best known to themselves; but the principal reason is the adjustment of the matter of drainage with other mines, concerning which I

will not attempt to go into detail at this time. The corporation also own a

Twenty-Stamp Mill,

Run alternately by steam and water power. It is complete in every particular, is situated on North Clear creek, some three-fourths of a mile from the mine, and is reducing some 385 tons of ore monthly from their own mine. The company are having considerable ore reduced at outside mills, and are selling ore to still other reduction works. They pass all their blanketing through the pans, of which they have six. The tailings are all washed down, saved, and sold to the smelting works. They have complete concentrating works, and but little goes to loss about this mill.

The Briggs Mine

Is owned by J. S. and C. H. Briggs, the latter named being superintendent and general manager; is located in Central City. The Briggs brothers have owned and worked the mine for the last fourteen years; there are two ledges or ore bodies running side by side in this mine, 240 ft. in length, known as the Briggs and Gregory; the former pitches east and the latter west, at an angle of about 12 degrees. The ore is mined principally for gold, but also contain 15 ounces in silver to the ton, about 10 per cent. of copper, a trace of lead, antimony and bismuth. The gold averages about \$150 per ton.

The Present Development

Of this mine consists of one shaft sunk on the Briggs lode to a depth of 560 feet, and one on the Gregory 300 feet deep, each sunk on the dip of the vein. Both hoisting works are run by the same engine, which is of about 100 horse power. This mine gives employment to about 20 men on an average, extracting about 35 tons of milling ore per day, and from two to four tons of smelting ore daily. They also have a 25 stamp mill of their own (of double issue) that has a capacity to reduce some 35 tons every twenty-four hours. The same engine runs the stamps and batteries that runs the hoisting works. I was shown some very fine specimens of free gold and sulphurets taken from this mine, that would grace any cabinet; it has the appearance of a very successful mine.

The Gregory Lode,

Formerly owned by the Black Hawk Gold Mining company, is at present owned by E. S. Jackson, of Providence, R. I. Mr. George E. Congdon is the resident superintendent; the company own numerous mines and mills. Their principal workings at present are confined to the Gregory mines, Nos. 1, 2 and 3, which they are developing through two principal shafts. Steam hoisting works are erected over each, with machinery adequate for the work to be done. Their principal shaft is down 586 feet on the dip of the ore body, (an angle of about 15°), except the first 240 feet, which is down vertical. Shaft No. 2 is down 531 feet. The former mentioned shaft is in two compartments, and has one fourteen-inch Cornish pump. The ore body in this mine runs from two to twenty feet thick, and averages about six feet. The ore is worked for the gold. When working in force they extract about 210 tons per week, 20 per cent. of which is smelting ore. This they dispose of in the vicinity for about \$150 per ton. The other 80 per cent. extracted is free milling ore and will average about one ounce of gold to the ton, (or as they figure it by the cord at seven ounces to the cord). At present they are only working sixteen men; preparing however for a larger force and future development. They own and run

Two Fine Mills,

Which combined have 85 stamps. One of these mills, containing 65 stamps, is run by steam; the other, a 20 stamp mill, is run by water. Combined they have a capacity of reducing 350 tons per week. The machinery of both these mills and at their hoisting works are a credit to any district. The rebellious ore of this country would puzzle many a Nevada and California mill-man, but here, after years of experience, they have learned to treat them so as to average from 65 to 70 per cent. of the assay value.

The Boston and Colorado Smelting Company.

The principal office of the company is in the city of Boston. The location of these works is in Black Hawk, Colorado Territory, and is generally known as Professor Hill's works; these are the only works of the kind in the United States, and there are but four others in the world, two of which are located in Swansea. Professor N. P. Hill is the General Manager of these works. Richard Pearce, F. G. S., is the Superintendent of the metallurgical and smelting department and among the first of his class in this country, a thorough metallurgist and perfect gentleman. The works of this company cover an area of some twenty acres; and ten different buildings are brought into requisition in the process of separation of the precious metals.

The Matte Process

In use here is a modified form of Ziervogel's process, which consists of the mixing of the silver ore of an adjoining district (Griffith or Georgetown) with the auriferous pyrites, containing copper as well, from this district. It is first worked in ordinary reverberatory calciners, for the silver. The iron pyrites are first roasted in heaps, to relieve them of the sulphur, and are brought down to contain only about five per cent. of sulphur. Afterwards it is passed to the smelters, which are reverberatory, and have a capacity of fourteen tons each daily. They have three of these, but only working two at this writing. For fuel, wood only is used. This matte previous to September, 1873, was sent to

Swansea to be refined, but this is now done here. The value of this matte is about \$1,000 per ton in gold and silver. They employ some 40 men in all departments, end turn out about 1,000 lbs of silver per week, that is 997 fine on the average. Since November, 1873, they have shipped about 10 tons of silver of the above named purity. In addition to the above, their present gold yield is about 1,000 ounces per week.

Collom Black Hawk Dressing Works Company.

A reduction works in course of erection, and nearly completed, by the above named company, is located in the suburbs of Black Hawk city. It is an incorporation of \$50,000 capital stock. Wm. Hancock, President; Peter W. Crosier, Secretary and Treasurer; Daniel Peters, General Manager, and Charles Collom, Superintendent. The general office of this corporation is at Trenton, New Jersey. The object of this company in erecting these dressing works, is to receive custom ores of a low grade, that cannot now be treated in this district and be made to pay. Some \$30,000 is being expended in the remodeling and erection of these works. The process is a wet one. The ore is first broken by the Blake rock breaker, partially screened, then passed through Cornish rollers, screened again, and passed through a combination of figs, each self-acting, when the different metals, according to their specific gravity, are separated. The cost of this will be about three dollars per ton. These ore will concentrate to about one-fifth. The capacity of the works will, it is estimated, be 100 tons daily, employing some 12 men.

L. P. Mc.

The Mining Interests of Calaveras County.

The condition of the mineral interests of the county—especially that portion of it bordering upon the Mokelumne—is extremely favorable. Both quartz and gravel mining are being successfully prosecuted, and the outlook for each of those interests was never more promising than at present. While it is true that in some portions of the county the results of operations in quartz are anything but flattering, yet such remarkable developments have recently been made in the northern and eastern sections of the county that failure, in isolated instances, does not darken the prospect in the least. In the West Point, Mosquito Gulch, Jesus Maria and Sheep Ranch districts the utmost activity prevails. Work is not only progressing upon ledges previously located, but new discoveries are being made, machinery erected, and everything connected with the business of quartz mining betokens present success and confidence in the future. In the West Point district—not to mention names—there are about twenty producing mines, and if the eagerness with which capital is seeking investment in that direction indicates anything, the number will be largely increased before the season closes. Every part of the district is occupied, and development is being pushed forward with a vigor never before noticeable. The Mosquito district has become one of the most promising in the whole mineral belt. The late unexampled yield of the San Bruno, together with very favorable results from other mines, are attracting general attention and have greatly stimulated enterprise. The ledges can be worked without any great outlay of capital, and as excellent milling facilities are afforded the district offers inducements second to none.

In the neighborhood of Jesus Maria some very rich discoveries have lately been made, and there is more prospecting being done in that locality than anywhere else in the county. Several sales of mining property in that district have recently been made to capitalists, and operations are being energetically urged in every direction. That district will give a good account of itself this season. Work is progressing upon a large number of mines in the Sheep Ranch district, prominent among which is the Wallace & Ferguson—a mine that for average richness of rock is not surpassed by any on the coast. The ore pays from \$60 to \$80 per ton, and it is mined and milled at a light expense. There are several other paying mines in the district, but the gross yield is nothing in comparison to what it would be if the required milling facilities were afforded. Generally speaking, however, the improved appearance and brightening prospects of the Gwin mine are doing more to strengthen faith and confidence in the permanency and extent of our quartz interests than all other circumstances combined. The Gwin is the representative mine of the county, and the fact that it is now emerging from the cloud under which it has for some time rested, with every assurance of a prosperous future, is regarded as a sure precursor of more permanent development in other localities.

Gravel mining is rapidly taking its place again as one of the leading interests of the county. A new era has opened in hydraulic mining, especially, revolutionizing the former method of working and achieving the most unlooked-for results. It is found by the system now in vogue that ground that would not pay "water money," worked in the style of former years, can be made largely remunerative, and hydraulics are being instituted in every direction. The success met with stimulates research, resulting in the location and working of paying claims wherever the necessary water can be obtained. Taking everything into consideration, the present condition and prospects of the mining interests of the county are encouraging, more favorable, in fact, than for several years past.—*Calaveras Chronicle*.

MECHANICAL PROGRESS.

Another New Motor—A Marvellous Claim.

The "Keeley motor" is the latest novelty which, it is assumed, is to take the place of steam. Mr. John W. Keeley, of Philadelphia, is the "inventor," and a number of prominent engineers of Philadelphia, New York, Jersey City, etc., certify to having witnessed the exhibitions, and tender their names as references for the correctness of the wonderful claims which are put forth with regard to its efficiency and practicability. The medium employed is said to be a cold "vapor" of a density that enables it, when admitted to a cylinder, with a piston one and one-sixteenth of an inch in diameter, to raise a weight of 150 pounds suspended from a compound lever, connected as 1 to 42, which is estimated as equivalent to a pressure of 7,800 pounds to the inch. Yet with all that pressure, coupled with expansive energy, it is claimed that neither the vapor itself nor the cylinder in which it was confined exceeded in temperature the common air which surrounded it! The inventor has demonstrated a pressure of 10,400 pounds to the square inch—the utmost limit of safety—but has not yet reached the full capacity of the invention.

The force is said to be derived from a peculiar "mechanical device" hitherto unknown. The power is produced "without heat, electricity, galvanism, magnetism or chemicals." The whole thing is simple, inexpensive and universally applicable.

The principle of application is to work with a small generator capable of sustaining a pressure of 20,000 pounds per inch; but to reduce this extreme pressure by allowing the vapor to expand into an intermediate chamber, from which it may be used at common steam pressure in any ordinary steam engine, in place of steam. No fuel is employed!

It is intimated that the invention was suggested by the remark of Faraday, that "every drop of water contains force elements equivalent to a very powerful flash of lightning." Perhaps Mr. Keeley has succeeded in developing and controlling that "force element;" if he has not done that he seems to have succeeded in hmbngging a goodly number of mechanical engineers of good standing among their fellows. "Every share of the stock has been taken, the offers of money having been greatly in excess" of what was wanted.

Keeley is not much behind the well-remembered charlatan Paine, who claimed that by his invention he could, with a two-quart cup, drive the largest sea-going vessels across the Atlantic at the highest rate of sailing speed; but those who invested in his enterprise made as little money as will the "eminent engineers" who are taking stock in the "Keeley motor."

PAPER IN THE ARTS.—The numerous uses to which paper and paper pulp are applied in the various departments of general industry, form one of the most interesting chapters in the history of recent mechanical and chemical progress. We have paper doors and window blinds, paper billiard balls, boats, and wash basins, paper clothes and curtains; and, not the least important, as recent experiments have demonstrated, paper car wheels. From an exchange we learn that a Connecticut railroad is about to make trial of these new wheels, which have been known to car builders for some time, though their general introduction has been hindered by the expense. These wheels are made by the following process: Sheets of common straw paper are forced into a compact mass by a pressure of three hundred and fifty tons. The solid mass of paper thus formed is placed in a lathe and turned perfectly round. After which, a hub is forced into a hole in the center, under a pressure of twenty-five tons. This paper wheel, or disk, is now forced, under a pressure of two hundred and fifty tons, into a steel tire, with a one-half inch bevel upon its inner circumference. Two circular iron plates are then bolted on to the tire to keep the paper filling in place. By this arrangement the steel tire rests upon the paper only, and is thus rendered more elastic, a quality of great importance, as regards both the safety and comfort of travelers.—*Builder*.

THE DIAMOND SAW MACHINE for sawing stone, which was noticed in these columns some months ago, is still making its way into favor. Those which have been put into operation still continue to give satisfaction, and the invention is gradually working its way outward from the home region of the invention. This invention will most undoubtedly prove a most important advance step in the important industry in aid of which it has been devised.

ALUMINUM FOR BURNERS.—J. Kidd, of 27 Leadenhall street, London, has patented improvement in gas burners, which consist in the application to argand or other burners of aluminum pure and alloyed, together with an adjustable check valve to the burner which regulates the light.

UNDERGROUND RAILWAY PROGRESS IN LONDON.—The length of underground railways now in operation in London is about twenty miles, and they are being extended in various directions. The additional track now in progress of construction is about four miles. The rails are laid at from 20 to 40 feet below the street pavements.

Machine Combinations.

The combination of several functions in the same machine is one that has much to do with manufacturing machinery, and constitutes what we may term a principle in construction.

The reasons that favor the combination of several functions in one machine, and the effects that such combination may have on the product of machines, are so various that it has led to a great diversity of opinions and practice among both those who construct and those who employ machines.

It may be said too, that a great share of the combinations we see in machines, such as those to turn, mill, and bore, slot and drill in iron fitting, are due not to any deliberate plan on the part of the maker so much as to an opinion that such machines are novel, and represent a double or increased capacity.

So far as this combination in machines been carried, that in one case that came under the writer's notice, a machine was arranged to perform nearly every manipulation required in finishing the parts of machinery; completely organized, and displaying a high order of mechanical ability in design and arrangement, but practically of no more value than a single machine tool, because but one operation at a time could be performed.

To direct attention to certain rules that will guide opinions and practice in this matter of machine combination, the following propositions should be considered.

First.—By combining two or more operations in one machine the objects gained are economy in framing, the same supports answering double purpose, and a saving of floor room.

Second.—In a machine where two or more operations are combined the capacity of such a machine is only as a single one of these operations, unless they can be carried on at the same time without interfering one with the other.

Third.—Combination machines can only be used with success when one attendant performs all the operations, and when the change from one operation to another requires but little adjustment and rearrangement in each case.

Fourth.—The arrangement of the parts in a combination machine have to be modified by the relations between them, instead of being adapted directly to the nature of the work to be performed.

Fifth.—The cost of special adaption and the usual inconveniences of fitting combination machines when their parts operate independently, generally equals what is saved in framing and floor space.—*Journal of Franklin Institute*.

COMPARTMENT SHIPS.—Notwithstanding the numerous losses of compartment ships, confidence in their superior safety has by no means abated. The late disasters to the "Ville du Havre" and the "Europe" are fully understood. Both of these, though compartment ships, went down very suddenly—the former in twelve minutes, because the doors between the compartments were left open, and the latter from some unexplained carelessness, although her abandonment is now believed to have been unwarranted. In contrast to the two ships here named, we have only a few days since learned of the unnecessary abandonment of a third—the "Amerique"—which was encountered the next day by a passing steamer, with only six feet of water in her middle compartment, and safely towed into port. This latter case affords a good illustration of the value of compartments.

It is obvious that, if a vessel were divided into the proper number of water-tight compartments, the chances of loss from leakage or collision must be very much reduced. So well assured are shipbuilders of this fact that this plan of construction will be more generally followed than heretofore, and the number and strength of bulkheads materially increased. Heretofore six or seven compartments have generally been given to a ship 400 feet in length. The compartments are now, however, being increased to double or treble that number. As an extreme example in this direction we may instance the new British war steamer "Indefatigable," which is to have 127 water-tight compartments. Perhaps compartment ships may yet lead to the desired solution of the shipping-in-bulk question in relation to California wheat crops.

IMPROVED STEAM CARRIAGE.—Mr. Charles Randolph, of Glasgow, has invented an improved steam carriage, adapted to street locomotion, which is said to be free from the objections urged against steam carriages in general. It is 15 feet in length, and consists of three divisions, viz.: the driver's box in front, the boiler and engine house in the rear, with a compartment for passengers in the center. It is carried on four wheels, two at each end. When filled with passengers, and provided with water, etc., for a journey, its entire weight is only about $\frac{1}{2}$ tons, and it will travel at the rate of about eight miles per hour on the average. A few weeks ago this machine was tested in the presence of the Duke of Sutherland, Lord John Hay and others, and the result of the experiment was in every way satisfactory. Mr. Randolph anticipates that the mode in which he applies steam power to his carriage may be adapted to tramway cars, omnibuses, etc.

IMPROVED CULINARY TONGS.—This is a pair of wire tongs, of which the middle part of the lower prong is bent upward above the other, and has a coil formed in it to give it elasticity, so that the points are held closely together. A thumb piece is affixed to the bend, by pressing down which the prongs are forced apart.

SCIENTIFIC PROGRESS.

The Magnetic Metals.

It is well known that, besides iron, there are a few other metals possessing magnetic properties, viz: nickel and cobalt in a strong degree; manganese and chromium in a feeble one. In the *Philosophical Magazine* we find a remarkable article on this subject, by Mr. W. F. Barrett, F. C. S., in which he endeavors to point out the similarity of these metals to each other in their physical and chemical properties. Thus, as to specific gravity, that of the thirty-eight known metals ranges from lithium 0.50 to platinum 21.5, a difference of nearly 21; whereas those of the three strongly magnetic ones are iron 7.8, nickel 8.3, cobalt 8.5, where the extreme difference is only 0.7. Their specific heat is nearly identical; their atomic one is the same; so also their conductivity for sound, heat and electricity. Their dilation by caloric, and the amount they lengthen by mechanical strain, are also identical. The enormous cohesive power of iron, nickel and cobalt, in the solid state, signalizes these substances as the most tenacious of metals, and their melting point is only exceeded by the platinum group of metals. They are not volatile at the temperature of the hottest furnace, but only by the electric spark, when they yield very similar spectra. As to their chemical properties, the combining weight of iron is 56.0; nickel, 58.5, and cobalt the same. Chemists class these three metals in the same group, from the similarity of their chemical behavior, and also the identity of their combining energy or atomocity. What has been said concerning the likeness of iron, nickel and cobalt, in many respects holds true of manganese and chromium. The former has lately been used to replace nickel in the alloy of German silver. The compounds of all these five metals are conspicuous for the brilliancy of their colors. This uniform coincidence suggests the practical inference that nickel and cobalt might be obtained in a malleable and ductile condition when submitted to a process similar to that by which wrought iron is produced.

Method of Assaying Lead Ores.

The ore or other substance is oxidized, and its metals converted into sulphates before reduction; the best agent for this purpose being sulphate of ammonia. The ore is mixed with an equal or double weight of sulphate of ammonia, according as it is supposed to be poorer or richer, and the mixture is ignited in a small crucible of porcelain, covered to prevent spitting. The mass, when cold, is treated with boiling water, acidulated with sulphuric acid and muriatic acid. By this means the sulphates and oxides of iron, copper, etc., are dissolved, while the lead and silver remain insoluble. This portion is washed by decantation, the washings being passed through a filter. This filter is next dried, and its ashes added to the dried insoluble portion. It is then mixed with muriatic acid and powdered zinc, in order to reduce the sulphate of lead and the chloride of silver. The metallic deposit is washed with water which has been boiled, or acidulated with sulphuric acid, and is then pressed into a compact mass. This is dried and heated with from $\frac{1}{4}$ to 2 parts its own weight of a flux composed of 13 grammes carbonate of potassa, 10 grammes carbonate of soda, 5 grammes of melted borax, and 5 grammes of farina. The whole is covered over with dried chloride of sodium, and the heat is raised by degrees to redness. When the whole is in a state of quiet fusion, it is submitted for a moment to a higher temperature. This process serves for determining lead and silver in white lead, red lead, ores rich in gold and silver, also antimony, tin and copper. If, in the assay of ores of gold and silver, the amount of lead is insufficient, pure oxide of lead is added.—*Chemical Review*.

REDUCTION OF SILVER SALTS BY HYDROGEN.—Dr. Russell, F. R. S., communicates to the Chemical Society, that thoroughly washed and purified hydrogen causes a precipitation of metallic silver from a solution of silver nitrate, the precipitation occurring much more readily in saturated than in dilute solutions. The gas employed was usually procured by the action of a saturated solution of copper sulphate on zinc, or by the action of water on powdered zinc and tin. After it has passed for about half an hour through a saturated solution of the silver salt, a dull greyish deposit is produced, which is succeeded by a bright crystalline deposit. A clear solution, through which hydrogen had been passed, became turbid and gave a precipitate of silver when heated. Similar effects were obtained when the solution was exposed to an atmosphere of hydrogen instead of causing the gas to bubble through it. The author has conclusively proved that these phenomena are caused by the hydrogen replacing the silver in the silver nitrate, producing hydric nitrate. But a secondary reaction also takes place between the nitric acid and the precipitated silver, which results in the formation of silver nitrate. Dilute solutions of nitric acid have little or no action on silver, as hydrogen precipitates silver as readily from a nitric acid solution as from an aqueous solution. It has long been well known that hydrogen will precipitate from their solutions the platinum metals and gold, and the above observations with regard to silver add to its importance as a reducing agent.

The Nebular Hypothesis.

Prof. Van der Weyde, of New York, in a lecture before the American Institute, some three or four years since, expressed the opinion that the nebular hypothesis of La Place might be modified, by the application of the demonstrated doctrine of the conservation of forces, to such a degree as to be elevated into a theory. This modification consisting in the substitution of gravitation as the principal cause of the contraction of the nebula, instead of cooling by radiation, has been accepted by La Place; *ergo*, instead of taking as starting point a nebula, expanded to an enormous bulk for reason of its high temperature, and contracting by the loss of heat, we accept now a cold nebula contracting by the action of gravitation to millions of nuclei, which in their turn, by the operation of the same law, fall together into different centers of gravity. Then, by the mutual destruction of the larger portion of their motion, heat is generated, which is greater in proportion to the amount of matter precipitated and the distance through which it fell; all according to the well-established laws of the mechanical equivalent of heat.

By modifying La Place's hypothesis in this way, we dispose of the fatal objection made to it by Prof. Pierce, that it does not account for the disposal of all the heat. Indeed, starting with a nebula expanded by a high temperature to an enormous bulk, far beyond the orbit of Neptune, La Place supposes it to cool until more than ninety-nine per cent. of its mass is concentrated in the sun, of which the temperature is still far beyond our conception. What then must have been the original temperature? and where has all this heat gone? No doubt that this hypothesis, accepted as starting point entirely too much heat, and is unable to explain what has become of it.

We see then how the principles demonstrated by the experiment of Count Rumford, who boiled water by horse-power; of Mayer, who heated air by compression; of Joule, who raised the temperature of mercury and other fluids by agitation, have served not only to solve the greatest mystery in the evolution of our planetary system, but of the universe in general.

Diamonds Made of the Carbon of Sugar.

Mr. Emile Mouier (France) publishes a statement in regard to the carbon of sugar. When large white crystals of sugar are perfectly burned, they leave only one hundredth part of one per cent. of ashes; and when heated to about 1,800° Fahr. in a closed vessel, without contact of air, the hydrogen and oxygen are distilled off, mostly in the form of watery vapor, while a very pure carbon is left behind, the quantity of which, according to the formula for sugar C₁₂H₂₂O₁₁ (corresponding with 72 parts carbon, 11 hydrogen, and 88 oxygen), should be 42 per cent.; practically, however, less than half this amount (18 per cent.) is realized as a very pure carbon, which is so hard that it will cut glass like a diamond, while its hardness is greater in proportion as the sugar is purer. But being quite porous, those parts which cut the glass are crushed at the same time. Mr. Mouier has succeeded in increasing this hardness by mixing the sugar with syrup, about 25 to 30 per cent., to a paste, which is then introduced into a porcelain tube hermetically closed at one end, and only partially closed at the other, so as to give escape to the gases, while it is burned at a red heat. In that way he obtained a carbon cylinder much harder which could cut glass, and was only crushed with difficulty, but still porous.

Honey also gives a dense carbon of the same properties as that described, and we should like to see experiments made by inclosing honey or sugar in cylinders of refractory clay, and exposing them to the flames of the hydro-oxygen blowpipe, or to submit them, as soon as most gases have escaped, to great pressure and heat at the same time. It may not be impossible to produce black diamonds in some manner of this kind.

Some of our readers may be aware that white transparent diamonds can be made, very small to be sure, but still genuine diamonds, by the slow crystallization of the carbon out of certain carbon compounds of organic origin; and it is believed that this is the true origin of the natural diamond.—*Manufacturer and Builder*.

HYDROGEN A METAL.—M. Dumas has communicated to the French Academy some curious experiments of MM. Troost and Hautefeuille on the hydrates of mercury or combinations of hydrogen with that metal. These combinations, it is said, so strongly resemble those which constitute the amalgams of mercury with silver and other white metals, that it is hardly possible to doubt that they are themselves amalgams, and hence that hydrogen is a metal, a fact apparently indicated in many other analogies.

A NEW COMET.—The discovery of a new and very bright telescopic comet is announced. Its appearance was first announced to the Academy of Sciences at Vienna; but it has since been carefully observed in this country. On the 17th of April it rose at 2 A.M., east one-half south, and a half hour earlier on the 24th. At that rate of motion it would rise at this time (May 8th) about half-past 12 A.M. Its motion is towards north and east.

A TEST for sulphate of alumina is that good alumina should be neutral, and such is almost soluble in absolute alcohol.

MINING AT COLUMBIA HILL.—The *Transcript* gets the following from a correspondent:

W. W. Nichols has been running regularly for several weeks, with every prospect of a large clean up. The mines of Hawley & Hustler on Kennebec Hill, are working, and at the last clean up were paying first-rate. The Eureka Lake company on Columbia hill, cleaned up last week in Richardson's mine, No. 1, and took out two hundred pounds of amalgam, which it is judged will refort \$20,000. The other mines in the vicinity are running with a full head of water, and every appearance indicates that more gold will be taken out this season than for many years past. Mining work all along the Ridge is lively, and the miners feel well.

MARBLE QUARRY.—Work has been resumed on the Placer county marble quarry, situated near Colfax, and large quantities will be shipped to San Francisco, during the coming season. U. S. Senator Jones, of Nevada, is to have a magnificent vault erected at Lone Mountain cemetery, San Francisco, the marble for which is mainly supplied from this quarry.

The new quartz mill of the California Consolidated company, near Nevada city, started up on Monday. The company now have two mills at work.

PLACER COUNTY.

QUARTZ MINES.—*Herald*, May 9: The Orleans is developed by two shafts 100 ft. apart and 75 and 85 ft. deep, connected by a drift 75 ft. from the surface. The main drift is 135 feet from the west shaft, and still driving east with fine milling rock and an abundance of free gold in sight. The entire length of openings show a compact and well defined vein of sulphureted ore, averaging about 3½ ft. in width. About 500 tons have been extracted and milled at the St. Patrick and Pugh's mills, which yielded from \$22 to \$25 per ton. The value of this mine can be well appreciated when it is known that the rock can be mined and milled at an expense not to exceed \$1.50 per ton, with mill on the ground.

The St. Lawrence mill is pounding on ore from the Hathaway ledge, which belongs to the St. Lawrence company. The mill is a first-class 12-stamp, water power, capacity 24 tons per 24 hours.

The Pugh mill runs exclusively on custom work, and has not lain idle a day for the past year for the want of rock.

The St. Patrick mill is at present lying idle, but will start up in about two weeks on ore from the Crater mine, which is being rapidly opened up by shafts and levels. The stopes are being prepared for extraction of ores.

The Bellevue mine is about one half mile distant. This mining property consists of a series of parallel veins, situated on Buckeye Hill. We find extensive surface works in progress. The Bellevue company evidently mean business, 6 shafts being sunk. Steam, water, horse and man power the auxiliaries. The principal works are on the Buckeye ledge, No. 1 and No. 2 shafts. Mr. Werry, who is foreman of this property, piloted us through the mine. In the face and back of the lowest level (240 ft.) the ledge is about 20 inches, well sulphureted, with free gold visible in the rock. A connection will be made with No. 2 shaft 200 ft. west of No. 1 in about six weeks, giving a solid block of ore 100 ft. by 200 ft. by 20 inches, or about 2,500 tons of high grade ore. Other levels will be immediately opened. The company are also developing several other veins of the series with good results. The present work is simply one of development, no ore being extracted but such as being taken from shafts and drifts.

News from Dutch Flat says the prospects for a profitable mining season were never more encouraging. All the hydraulic mines are at work in full force, and their run promises to extend until much later in the season than usual, owing to the abundant supply of water, and the unusual depth of snow in the mountains at this season of the year. The same encouraging news comes from the large hydraulic mines on the divide.

IOWA HILL.—Everything looks prosperous thereabouts now-a-days, and a large force of men are employed on the canal and ditch. Money is plenty and everybody is jubilant, with a fine prospect in view when the water is accessible for working the rich gravel beds in that vicinity.

PLUMAS COUNTY.

WORKING.—*National*, May 9: The Dutch Hill Co. have twenty men at work, and the water, in all probability, is now through their ditch. With the immensely rich ground that the company are known to have, and the certainty of a good water season, they are sure of a mint of money.

SAN DIEGO COUNTY.

SAN DIEGO QUARTZ.—*Grass Valley Union*, May 10: The Bever Quartz Mining Company is an incorporation organized in this place to mine in Banner district, San Diego county. Work has been commenced on their location, under the superintendence of David Norrie, an experienced miner from this district. The company have recently received samples of rock from their claim, taken from the surface and a few feet below. The rock at first sight does not strike the observer favorably, as it does not show mineral, and but little trace of gold; but upon pounding it in a mortar very handsome results have been obtained in free gold. The district is coming into favor with mining men in different parts of the State, and it is confidently believed at no distant day it will take rank as one of the leading quartz mining districts of the State. A test of the rock from Bever mine has been made, and gives a result

of \$45 per ton, worked as by mill process. For rock that exhibited scarcely a trace of gold, this is an excellent showing. The vein from which the rock was taken is seven feet in width and would insure a good profit from a yield of \$10 per ton.

SISKIYOU COUNTY.

GOON RESULT.—*Yreka Union*, May 9: We learn that a company of Portuguese cleaned up in their claim on Cherry creek one day last week, some \$1,300 as the result of about ten days' run. It is expected that they will take out from \$12,000 to \$15,000 during the season.

SOLANO COUNTY.

MORE CINNABAR.—*Vallejo Chronicle*, May 9: Berry Shouse has struck a cinnabar ledge on his ranch, about 400 yards west of the St. John mine. He has now been at work developing the strike for several weeks. Parties who have just visited the place represent that there is every prospect that he has struck a regular lead. Of the richness of the ore which has thus far been taken out there is no question. In some of the pieces the virgin quicksilver is found. A shaft of about 35 or 40 feet in depth has been sunk, and a drift run about the same distance. There is now estimated to be between \$6,000 and \$8,000 worth of ore on the dump.

TRINITY COUNTY.

TRINITY CENTER.—*Cor. Journal*, May 9: Mining interests are flourishing. Some of the claims here are in full blast, while others are preparing for a heavy summer's work. Haskins, Rumpfelt & Co. are "making the fur fly," so to speak, on Shoo Fly hill, with their big pipe. Hall & Williams are at present busily engaged in repairs on their ditch, employing several men. Extensive caves have lately taken place in the banks of Bloss & Co.'s claim. E. Enwright is working his diggings to a good advantage.

Work on the ditch from West Weaver across the Oregon mountain is being pushed forward as rapidly as circumstances will permit. A force of 200 men is employed, and 30 more were expected to begin work on Thursday morning. The weather has been very unfavorable for the prosecution of this enterprise, but the company expect to have the water at work by the first day of June.

COPPER MINES have been discovered on Oak Run, from which lumps of pure copper, weighing from 2 to 6 pounds each, have been taken by prospectors.

TULARE COUNTY.

MINERAL KING MINES.—*Delta*, May 7: There are indications of stirring times close at hand. Many parties are already on the ground and in the vicinity, while the notes of preparation are everywhere heard in the towns of this and adjoining counties. Harry's Bend, on the east Kaweah, is the center of the district. Silver City is five miles west, on the direct route from Loveland's to Harry's Bend, via Dope Camp and Bruin's Retreat. There is no snow at Silver City, and only 5 ft. at Harry's Bend; and with ordinary weather, the trail will be clear to Silver City by the 15th or 20th instant. Several families are already going there, and cabins for others are being built. There is a good trail from Mount Hope to Silver City. A school will be opened at this place on or about the 15th of June. Whipsawyers, board and shake makers, by the score, are working up timber at the Bend, and find immediate sale for all they can produce. We should not be surprised to see a larger rush for these mines than has ever taken place in the State, and many fortunes will be suddenly made.

COAL.—*Times*, May 9: We were shown by Mr. T. C. Hunt, of the Exchange Hotel, some fine specimens of anthracite coal, found in the foothills about 20 miles from Visalia. This is quite a valuable discovery, and will, no doubt, prove to be a great source of wealth to this county. The vein has not been thoroughly examined, but there is no doubt but that coal exists in abundance. The wealth of our mountains is yet unknown. It is with those that first venture to be rewarded.

TUOLUMNE COUNTY.

ANOTHER CLEAN-UP.—*Independent*, May 9: The amalgamators at the Golden Gate mill cleaned up on the 3d instant, after a 5½ days' run. They crushed 38½ tons of rock, from which they extracted 33¼ ounces of gold, \$658.13, or \$19.25 per ton. The gold in this rock is so very fine that to save it care has to be used in crushing, and a light fall given to the stamps, which accounts for the small number of tons reduced per day. With a fall and a rush, such as is used in northern mills, where the gold is heavy, it would cause a waste and loss enough to make the difference between a paying and a non-paying mine.

The Alpha Table Mountain Co. is now running a gangway through the gravel, with excellent prospect. The channel is running direct for the Omega. Mr. Wyatt, Superintendent of the Omega, will start in as soon as the Alpha Co. strike their line. The Omega is expected to be the king-pin mine of Table Mountain.

FROM GARROTE.—*Cor. Independent*: The mining interests are looking up a little in this part of good old Tuolumne. Mr. Du Pratt is pushing ahead the tunnel on his claim as expeditiously as possible, and expects to strike the vein within 20 or 25 feet. L. K. Hough and Fred. Cope, who struck the rich pocket a while back, are now driving a tunnel to tap the pay shute at a greater depth. Woode & O'Flannigan are sinking a shaft on the Cosmopolitan claim, and expect to get good results for their labor. Lancy & Pool have discovered a very rich and extensive mine in Second Garrote; from present indications it bids fair to develop into one

of the best mines in this part of the county. I think I am safe in saying that they have six feet of vein matter that will yield 10 or 12 dollars per ton. Rocca is working a full force of men in his hydraulic claim; he uses about 800 inches of water, with a pressure of about 200 feet. Chandler & Beal, owners of the Keystone ditch, are putting down a large flume in their claim, and expect to commence washing on a grand scale, in a few days.

Nevada.

ELY DISTRICT.

RAYMOND & ELY.—*Pioche Record*, May 2: The cross-cut from 1,200-ft. station is now 142 ft. in length, and must very soon cut the ledge. The 10th level, 200 ft. above the lower one, has been run to the western line without finding ore to any great amount; bunches of good rock were scattered here and there, but were not of much importance. In the upper levels stoping is going on as usual, but with a reduced force. During the past week little ore has been shipped, it having been allowed to collect in the ore-house. At the mills and mine there are altogether about 700 tons collected—about 600 tons at the mills and about 100 at the mine. It is probable that the mills will resume crushing in the course of next week.

MEADOW VALLEY—No. 3.—Sinking has been resumed on the shaft and it is now a short distance below the point where the drift is started to connect with the Raymond & Ely 1,200-ft. level. On the 9th the eastern drift is now in 749 ft., just about opposite to the summit, or No. 5 shaft, with which a connection will be made. The stopes on the western side look about the same, and the usual quantity of ore is being raised from them.

The summit, or No. 5 shaft, is 1,030 ft. deep, and the work of sinking is going on as usual. At a depth of 1,002 ft. from the surface, a station will be opened and connection made with the drift on the 9th level of No. 3. At the mills, things are going on as usual, with no change of any moment to note.

WASHINGTON AND CREOLE.—The shaft from the Mazepa works has reached a depth of 750 ft., and about 140 ft. more to sink to connect with the lower level. There are 120 tons on the dump, which will be shipped in a few days to the Floral mill for reduction. Since our last report, the Superintendent has sent bullion below to the amount of \$1,350, being the closing shipments from the last crushing.

PORTLAND.—The Superintendent, Mr. A. J. Blair, has commenced shipping ore to the Newark, late the Amador mill, and has already sent about 50 tons.

HAYANA.—This mine is situated just over the shoulder of the hill east of the American Flag. The shaft is part of its depth perpendicular, and the remaining portion an exceedingly steep incline, varying but slightly from the vertical. At a depth of 270 ft. from the surface, a drift has been opened on both sides of the shaft following the line of the ledge. The eastern is in 16 and the western 25 ft. The face of both is occupied entirely by the ledge, most of which is good milling ore. The work of sinking the incline is carried on as speedily as possible. A good whim has been erected over the shaft, and by its means 8 or 10 tons of ore are being hoisted daily, and is being piled on the dump.

AMERICAN FLAG.—At this mine all is activity and bustle. During the past week 194 tons of ore were sent to the mill, making a total of 350 for the month. The mill is now and has been for the past two weeks running on the company's own ore. Above the 9th level the stopers are busily at work taking out some very good looking ore, of which a number of tons is being raised daily. In all respects the mine of late has greatly improved.

PIOCHE.—The shaft is now 750 ft. in depth. A considerable amount of ore is being taken out of the mine on shares, which method is both effectual and economical. We saw on the dump a pile of some of the richest ore we have seen in Pioche.

SILVER PEAK.—Five hundred and fifty ft. from the surface a station has been opened and a drift commenced, following the line of the ledge. It is in 30 ft., and the face of it shows 3½ ft. of good ore.

CHIEF OF THE HILL.—The faces of the drifts occasionally show some very rich ore, but at present not in sufficient quantities to pay.

Nevada.

WASHOE DISTRICT.

OPHR.—*Gold Hill News*, May 7: Cross-cut No. 2, on the 1,300 ft. level, has reached the east clay wall of the ledge, which at that point shows the formation of the ledge and east wall to be as solid and perfect as in any mine on the lode. Two drifts have been started from this cross-cut, one north and the other south, both of which are still running through ore that assays from \$180 to \$300 per ton. The winze, from the 1,300-ft. level, has made connection with the upraise from the 1,465-ft. level, giving a fine circulation of air in that portion of the mine.

SUTRO TUNNEL.—The main header to-day is in 5,868 ft., and the rock being somewhat softer, correspondingly better progress is being made. One Burleigh drill was put to work at this point on Saturday last, since which time, despite the delays incident to a first trial of new machinery with inexperienced hands, a very considerable advance over hand labor was the result. As soon as the carriages ordered shall have arrived, three drills will be put in operation, when a very considerable advance over present progress will be recorded. Drifting both east and west, on the line of the tunnel,

will be proceeded with at once. A portion of the machinery for the new air compressor for this shaft having arrived, it is expected that the Burleigh drills will be put at work in both east and west headings next month.

SILVER HILL.—The flow of water from the face of the south drift, at the third station level, is gradually subsiding, and the quartz in the face of the drift is of a very lively and favorable character for ore developments. The raise from the south drift at the first station level, in the old St. Louis chimney, is making rapid headway, encountering some very fine ore. This raise is being made for the double purpose of prospecting the ground through which it passes, and making an air connection with the old St. Louis works, thereby ventilating that portion of the mine.

CONSOLIDATED VIRGINIA.—The ore breasts north and south on both the 1,300 and 1,200-ft. levels continue to open splendidly, proving more and more the richness and permanency as well as the great extent of the ore body, which has now been proven to extend from the 1,000-ft. level down to the 1,400-ft. level, where the ore is more solid, the ledge wider, and the quality of the ore even richer than on the levels above. All the mills are kept steadily running on ore from the mine, and a dividend may soon be looked for.

UTAH.—Prospecting the body of ground lying between the old upper works and the 400-ft. tunnel level, has developed nothing new during the week.

CALEDONIA.—Raising up and cutting out the third compartment of the shaft from the third to the second station level is rapidly approaching completion. The repairs to the north drift on the second station level are nearly completed, and work in the cross-cut from this drift will soon be resumed.

YELLOW JACKET.—Sinking the main incline is making good headway, notwithstanding the extreme hard character of the rock penetrated.

BELOCHER.—Sinking the main incline is making slow though steady progress. It is now down 16 ft. below the 1,500-ft. level, the bottom in extremely hard blasting ground. The ore stopes on the 1,200 and 1,300-ft. levels are holding out and yielding handsomely. The ore breasts on the 1,400-ft. level are opening out splendidly and promising a rich yield for many months to come. Daily yield 550 tons of ore.

MINN.—Sinking the shaft is making rapid headway, the rock in the bottom blasting and blocking out finely. The rock from the shaft is being dumped in the ravine alongside of the hoisting works, so as to form a large and convenient yard for timbers, wood and other material for the use of the mine. This yard will be nicely arranged, having just slope enough to give the greatest ease in the handling and carrying of heavy timbers into the hoisting works and mine.

CROWN POINT.—Daily yield 550 tons of ore. The ore stopes throughout the entire mine are looking well and yielding the usual amount of good milling ore. The ore in the middle winze on the 1,400-ft. level continues of rich quality. Sinking the north winze on the 1,400-ft. level has been discontinued on account of water.

BALTIMORE CONSOLIDATED.—Sinking the main shaft is making steady progress, the rock in the bottom working out finely and the water giving less trouble than for the past two weeks. Three car loads of the spruce pine timbers for the foundation and frame timbers for the new machinery were shipped from Dutch Flat, California, on the 3d, and are expected to arrive at the mine to-day.

BUCKEYE.—In our report last week we stated that a prospecting drift south, which was in thirty feet, had been started at the first station. We should have stated that the drift was started at the point of discontinuation of the old works 400 ft. south of the old shaft. The drift is now in fifty-five ft., and will have about 150 ft. further to run to reach the point where it is expected that a chimney of good ore will be found.

SUCCESS.—The up raise from the east drift at the first station level in the mill shaft shows quite an improvement in the width of the ore vein, as well as the quality of the ore encountered. The ore vein is now 3½ ft. in width, of good milling ore.

GOULD & CURRY.—Sinking the double winze from the 1,700-ft. level is making the usual steady progress. The face of the north drift on the 1,700-ft. level is still in hard blasting ground.

McMEANS.—The main tunnel is in 680 ft., and the breast is in low grade ore, with indications of a near approach to the ledge. A fine stream of water issues from the mouth of the tunnel, sufficient to supply a strong air blast, arrangements for which are now being made, as the air is becoming too much deoxidized to enable lights to burn freely.

GLOBE CONSOLIDATED.—Sinking the main incline is progressing 2½ ft. per day. The main west drift on the 400-ft. level is making steady headway.

JULIA.—The main south drift at the 1,000-ft. station is in 298 ft. from the main west tunnel, the face is tough clay with some quartz. The east drift from the main south drift on the 1,000-ft. level is in 332 ft., the face is a mixture of clay, quartz and porphyry.

DAXTON.—The ore breasts on the first, second and third station levels are all looking well and yielding the usual amount of good milling ore, keeping both Woodworth's and Briggs' mills steadily running.

SIEBRA NEVADA.—New shaft down 410 ft. The sluice tunnel is completed. The raise from

Quicksilver and Borax.

The Post of this city tells the following story concerning the discovery of quicksilver on the property of the California Borax Company:

The California Borax Company, of Borax Lake, once had a good business in borax and sulphur, but the competition of other and more available fields gradually drove them out of the business, and for the past five or six years the California Borax Company has rested in its labors. It has preserved its organization and its property, and yet was held at little worth by the stockholders beyond the value of real estate and privileges owned by the company. During the renewed search for quicksilver, stimulated by the recent advances, the lucky thought struck some one to assay the dark, porous, coke-looking rock which covered much of the ground of the California Borax Company. The result of that first assay was so encouraging that other samples were assayed, with still more gratifying results.

A Well-kept Secret.

The facts were made known confidentially to a few friends, and the California Borax Company had an offer for their entire property. During the negotiations nothing was dropped which could put the Borax Company on its guard. On their side they had what they once believed astounding wealth in borax and sulphur, but these dreams of perpetual dividends had been dissipated for years, and an offer equivalent to \$10 a share for the stock all around seemed a very good chance of washing their hands of an unproductive property.

A Bad Bargain Consummated.

The sale was consummated with considerable satisfaction by the vendors, but no sooner was it concluded than they learned that they had sold for a song what is believed to be the richest and most promising quicksilver mine in the world. It is needless to say there was much dissatisfaction on one side and corresponding elation on the other. Those who were out thought that the "ins" should have given them a show, and the "ins" said that the Borax Company should have informed themselves of what their property was worth—the old company could not expect the lucky finders of the treasure to go to the directors and say: "Gentlemen, you have quicksilver at Borax Lake, and are neglecting a fortune." To make the matter more vexatious, some of the borax company have been intimately connected with quicksilver mining, and ought to have made the discovery themselves, but do not appear to have given it a thought. Yet, where there were large quantities of borax, of sulphur, of soda, soda springs and medicated waters, was not the unluckiest spot in California to look for cinnabar.

The Quicksilver Deposit.

The sulphur banks are found to contain, by assay, 40, 50 and in some cases, 60 per cent. of the valuable liquid metal. The assays of ore taken almost promiscuously from chunks of the material of which these banks are composed yield more than the selected area of the New Almaden ever did even in its best days. Add to this that the prices which now rule in the quicksilver market are double, or more than double, what the New Almaden got for its production when a little of its stock was a small fortune. Two car loads of this sulphurous ore have been brought to the city and will shortly be reduced, which will solve the last problem. Can the ore be easily reduced, or is it rebellious? Riotte & Luckhardt, the assayers and analysts, say that from the facility with which it assays, so far from being rebellious, it will, in their judgment, prove as easy to work for quicksilver as it is for sulphur. The new owners are in high spirits, and will, as soon as they have satisfied themselves with the preliminary experiments, erect first-class reduction works, furnaces, etc., and go into the business on the largest scale.

Good News.

The prospect of a large increase in the production of quicksilver is good news for miners, for unless new and important discoveries had been made, either the business of silver mining must atop at its present limits or the price advance to that point which would prevent all milling of low grade ores. This question of quicksilver for the future is one that has harassed the miners for years, and during the past few months the advance in price has made it assume the most formidable proportions. The question of who is the seller and who the buyer is secondary. The fact that hundreds or thousands of tons of ore yielding from 40 to 60 per cent. of metal are lying in loose banks in Lake county, ready for shipment to any reduction works that can resolve them into a merchantable article, is the important fact. New Almaden only produced 11,042 flasks in 1873, and New Idria and the Redington 11,708 flasks between them. All the other quicksilver mines in the State, including Cerro Bonito, San Luis Obispo county, which produces about 50 flasks per week, do not produce over 500 flasks per month. The New Almaden yielded, in 1865, with 47 per cent. ore instead of five per cent., which it is now working on, 47,194 flasks. If the Borax Lake answers to its present promise it will, when fully developed, and the requisite works erected, yield 100,000 flasks a year, and be a far more valuable property than all the present quicksilver mines in the world.

John Barrett and seven of his friends, among whom there is one of the wealthiest stockbrokers on California street, are the lucky owners. If they will only work the mines diligently,

and let prices be ruled by demand, instead of by restricting the supply, the Pacific coast will benefit not only by their wealth, but by the stimulating effect it will have on silver mining generally.

The Property.

The area of the borax company's estate, which it has now parted with, is 4,000 acres, well wooded, finely watered, and nine miles of frontage on the lake. There are many buildings on the ground, but most of them have gone to wreck for want of care and occupation. The site is very beautiful for residences, hotels and saunteria, and when the mining business makes ample returns, there is no doubt the company will build up a town that, while profiting by the business of the mine, will become a pleasant and fashionable resort.

The Belmont Mine.

As usual, our report of the Belmont mine (as well as all other mines we have mentioned in the district,) in last week's issue, was fully as correct as though the lower workings had been personally visited from day to day. The paper went to press in the afternoon of Friday, with the report of the mine, which was obtained as best it could be, from time to time, on what could be relied on, and our own examination of the several drifts some eight or nine weeks since, with a little prophecy combined. On the following day (Saturday) specimens were brought into town of a very high grade, indeed decidedly more favorable indications than were extracted from the Cassel deposits in December last; the ore being free from wire silver, and will yield considerably higher, in our judgment. The drift in which this body of ore was found is in the Transylvania ground, there being some fifty or seventy feet in length of ledge drifted alongside of that shows ore of high grade. Of course, it is impossible to say what it will yield to the ton by mill process, but in all probability the entire ledge will average from \$125 to \$175 per ton. As progress is made the same quality of good ore is found. The distance in drift from the Canfield shaft is so great that the air has become foul, rendering the running of it rather slow. Some little distance ahead, north, a winze is being sunk in the Transylvania ground, for the purpose of furnishing air, which will occupy several days in accomplishing. Once that is completed, more men will be put to work and more rapid progress will be made. The stock, to-day, should be worth \$10 or \$12. From the Moore & Martin ground ore is being steadily raised, on which the Monitor-Belmont mill is kept running most of the time.—Belmont Courier, May 2.

PANAMINT MINES.—M. J. Byrnes, one of our Inyo pioneer prospectors, has for several months been out at Panamint and came in from there a few days ago. He says that truly that district has the most promising outlook of any he has seen in all his wide prospecting experience. The Jacobs' five-stamp mill machinery is being taken in there and will be set in operation at the earliest practicable moment. This mill is calculated to crush fifteen tons of ore per day and concentrate in proportion, down to about one ton in ten, the pulp then to be shipped to Los Angeles or San Francisco for final reduction. The same system is also to be adopted with the twenty-stamp mill, for the building of which preparations are now being made. These two mills will thus afford quite an item in the way of freights. The toll-road through the cañon and the Los Angeles subscription-road connecting with it, will be completed in about thirty days. In fact, the latter is now ready for use. Nothing is being done about the road direct from Passamores', but it is a matter of considerable importance to the rest of the county that that road should be put through. Its cost will probably not exceed \$1,500. There is plenty of wood and water in Panamint, but not a spear of grass nearer than Passamores', so that Kern and Los Angeles counties will furnish all the provender for the district, unless this road is built.—Inyo Independent.

HOW TO SET THE HOUSE ON FIRE.—1st. Rub your furniture with linseed oil, and preserve carefully the old greasy rags used for this purpose, in a paper box in an out-of-the-way place. 2d. If the fire in the stove does not burn well, pour benzine or kerosene on it from a well-filled gallon can. 3d. When you light your cigar or the gas, throw the burning match—no matter where, and don't look after it, even if it gets into the waste-paper basket. 4th. Put a burning candle on the shelf of a closet, and forget all about it. 5th. Always read in bed until you fall asleep, with a burning candle near you. 6th. Especially for builders: Put the ends of the wooden beams into the flue walls; and if you build hot air furnaces, be careful to use as much wood as possible in their construction. 7th. Always buy the cheapest kerosene you can get.—Builder.

IMPORTANT TO SNAKES.—An English exchange says that carolic acid is a deadly poison to snakes, and experiments have proved that a few drops are sufficient to cause almost instant death to the dreaded cobra, and suggests that it might be invaluable in India and other tropical countries.

PRESERVING WOOD.—The nature of a new invention consists in filling the pores of the wood with lime, or a mixture of lime and sand.

Eureka Bullion.

The Eureka Sentinel, of the 3d inst., in an article on the mines, speaks as follows of the bullion and charcoal:

The week's coal receipts have been as follows: Eureka Consolidated, 13,000 bushels; Richmond, 13,054 bushels; Ruby, 4,000 bushels; Hoosac, 8,000 bushels; in all, 38,054 bushels; an increase over last week of 5,615 bushels, which must be accounted a very good result, indeed, and one which bespeaks the animation pervading this one arm of our industrial pursuits.

The bullion product for the same period has been: From the Eureka Consolidated furnaces, 700 bars, aggregating 91,000 pounds; and from the Richmond, 1,467 bars, making 124,695 pounds, or a total of 215,695 pounds of crude bullion. These figures give an increase over the amount produced last week of 16,060 pounds.

The shipments by Pritchard's Fast Freight Line, for the same time, were: From the Eureka Consolidated, 177,950 pounds of crude bullion; and from the Richmond, 100,287 pounds of refined bullion; in all, 258,237 pounds, showing an increase of 143,837 pounds over and above the quantity shipped at the date of our last report. From the Newark mill, per Superintendent Baron, there were received, on last Monday, at the office of Wells, Fargo & Co., at this place, two bars of silver bullion, 416 fine, weighing 2,029 ounces; and on Wednesday, two bars, 635 fine, weighing 1,707 ounces. The value of the latter was \$1,399 71-100.

MORE CINNABAR.—The Vallejo Chronicle says: Berry Shouse has struck a cinnabar ledge on his ranch, about four hundred yards west of the St. John mine. He has now been at work developing the strike for several weeks. Parties who have just visited the place represent that there is every prospect that he has struck a regular lead. Of the richness of the ore which has thus far been taken out, there is no question. In some of the pieces the virgin quicksilver is found. A shaft of about thirty-five or forty feet in depth has been sunk, and a drift run about the same distance. There is now estimated to be between \$6,000 and \$8,000 worth of ore on the dump. Shouse has now got eight men employed on the mine. If further developments shall justify, he will erect a smelting furnace.

HIGHLAND.—The Pioche Record says: "On Monday we took a trip over to Highland and found the newly-located village of Williamsburgh flourishing gaily. The sound of hammer and saw was heard wielded by the men engaged in erecting new buildings, and everybody appeared busy and hustling around. The mill started on Thursday last and worked very smoothly, and on Monday morning about 200 pounds of amalgam had been collected and was rapidly increasing. We did not go up to the mines, but were told that they were looking very well. After a long period of depression, from all appearances, Highland will yet come out all right. We hope that this will prove to be so, for it will not only be greatly to the advantage of the Highland Consolidated, but also to Pioche."

FILING HANDSAWS.—In filing handsaws that are intended to cut only one way, the majority of mechanics file toward the handle, which leaves the teeth with more bevel on the back than on the front, which is caused by the taper of the file. A few persons file their saws toward the point, which gives more bevel to the front or cutting side of the teeth. Some think that the back side of the teeth should be filed nearly square across, and that the saw will cut equally well and remain sharp much longer. The front side of the teeth should be beveled to suit the timber; soft wood requires more bevel than hard wood.

DEEP SEA SOUNDINGS IN THE PACIFIC.—Despatches to the Navy Department report that the United States steamer "Tuscarora," Commander Belknap, engaged in taking deep sea soundings, left Honolulu March 18th, and arrived at Yokohama, Japan, April 22d, having made 72 casts—the deepest of which was 3,287 fathoms. She will now examine the southeast coast of Japan, and from thence carry a line of soundings to Tonago, Aleutian Islands, and from thence complete the arc of the great circle to the point reached last fall, from Puget Sound.

SALES OF MINERAL LANDS.—Sales of mineral lands under the Acts of 1866, 1870 and 1872, reported to the General Land office to March 1st, 1874, amounted to 44,292 acres, as follows: Arizona, 210 acres; California, 28,031; Colorado, 23,250; Idaho, 7; Montana, 916; Nevada, 1,740; New Mexico, 52; Oregon, 1,346; Utah, 4,801. In the Central City District of Colorado there have been 500 entries, with an average of two acres to each entry. Many of these entries contain less than a quarter of an acre.

TO MAKE HAIR CURL.—The method employed by professional workers in hair is as follows: Wet the hair to be curled, wrap it smoothly around a cylindrical stick or tube of proper size, tie it in place, then put it in water and boil it two or three hours, remove it from the boiler, wrap it carefully in newspaper and bake it in a moderate oven for an hour. Thus treated, it will stay in curl permanently.

SMELTING WORKS are being erected at Hurlston, seven miles north of Heber City, Utah.

The Stickeen Mines.

Purser Vanderbilt, the courteous officer of the steamer "California," has given us the following items of interest from the above mines:

On the last trip of the "California," about 60 men were brought to Fort Wrangel. The steamer "Otter," which sailed from Victoria a few days subsequent to the "California," also took away a number of persons destined for the reported auriferous regions. There are at Fort Wrangel a large number of persons waiting anxiously for the river to open. At Wrangel the weather is reported beautiful and spring-like. Under the vernal influences of the sun and wind, all the snow and ice have disappeared from the vicinity. Everything indicates an early opening of the river.

Mr. Sylvester, the expressman, arrived at Wrangel on the evening of the 26th ult., from the diggings. He made the round trip in 21 days, and was 11 days in coming down. He reports that the weather is rapidly moderating, and every indication is fair for the early clearing of the Stickeen. Ice and snow in many places had already begun to thaw. Four hundred men were in the gold-bearing regions at the time of the messenger's arrival. About that number were scattered along the route between Wrangel and the mines. Most of them the messenger found engaged in building boats. As soon as the river shall open, these persons will launch the crafts, place in their stock of provisions and ascend the stream without any difficulty. Should the present genial weather continue, it is confidently anticipated that there will be a general breaking up of the ice in the river within two or three weeks at the furthest. Sylvester brought down 250 ounces of gold dust on his last trip, which had been taken out during a few weeks preceding his arrival at the mines. Fires were being built every day in order to thaw out the ground and thus enable the miners to commence operations, such was the prevailing degree of anxiety to test the diggings. The messenger found every one in high spirits and confidently awaiting the coming of spring. Wherever mining was being done, from \$12 to \$30 per day is realized per man. From all that can be determined from present prospects, it is confidently thought that the precious metal exists in large quantities in those regions; at least, all appear in good hopes, and are willing to take their chances. Within the next 30 days there will be from 1,000 to 1,200 men at the diggings, and the result of mining operations will then be known to a certainty. Large quantities of provisions were found by the messenger scattered along the river, which had been thrown away by those persons who were eagerly pressing their way towards the mines. Provisions in the mines were quite scarce, and as a natural consequence, dear. There are quantities of provisions at Wrangel, which will be forwarded to the mines immediately on the opening of the river.

For the present, the steamer "Eliza Anderson" has been hauled off the river. Only the steamer "California" and "Otter" are touching at Wrangel. Two steamboats—engines and machinery for one of which were cast at the Willamette Iron Works—are now being constructed at Victoria. These boats are being built with express reference to run on the Stickeen river. Both are rapidly approaching completion, and will be ready to run by breaking up of ice. Intense excitement prevails everywhere concerning these mines; and the \$4,000 in dust brought down by the expressman only tends to confirm their predicted richness, and to add to the general feeling. On the next trip of the "California" a large number of gold fevered individuals will be landed at Wrangel, both from Portland and Victoria.—Victoria Advertiser.

A WATER-PROOF PAPER, transparent, and impervious to grease is obtained by soaking good paper in an aqueous solution of shellac in borax. It resembles parchment paper in some respects; if the aqueous solution is colored with aniline colors, very handsome paper, of use for artificial flowers, is procured.

AN INDELIBLE AND UNBLEACHABLE INK for writing and printing on cotton and woolen fabrics is made of equal parts of copperas and vermilion, powdered and sifted, then ground with linseed oil and finally pressed through linen; the thick paste thus obtained being used.

BLADEN MINES.—Some one in San Diego expresses the opinion that within six months from the commencement of earnest work, more bullion will be taken monthly from the Bladen mines than has ever been taken from all the mines of San Diego county.

FOR sizing lace curtains, make a strong solution of four parts of borax, in hot water, to which add twelve parts of white shellac, and three parts of starch and isinglass, the latter two being first reduced to the form of a jelly by hot water.

BRANHAM & Co. have purchased the Diamond Mountain claims in Lassen county, and intend putting up hydraulic works as soon as the snow is melted away sufficiently to admit of approach.

DURING the month of April bullion to the aggregate value of \$1,760,285.75 was shipped from Virginia City by Wells, Fargo & Co.

GOOD HEALTH.

Extract of Meat.

In a report by Dr. Koechlin on the nutritive value of bread and of extract of meat, submitted to the Chemical Section of the Societe Industrielle de Mulhouse, and published in their Bulletin for January, 1874, we find the following details and opinions given: The trial of mixing extract of meat with bread is worthy of attention. This extract, which until lately was considered the perfection of concentrated food, did not increase the nutritive qualities of bread in doses of from five to twenty grammes a day given to a carnivorous animal. When the product first appeared in commerce, it became the object of general infatuation, which still exists with some people. Numerous trials of its nutritive properties have been made, and science has now obtained results which somewhat diminish the high opinion at first entertained of it. It has been proved: 1st, that in large quantities the extract of meat becomes a poison; 2d, that it cannot be looked upon as a true aliment but only as a condiment. Kemmerich having fed some rabbits upon Liebig's extract, they invariably died when given a dose representing from 800 to 1,200 grammes of meat. The writer himself, having consumed fifteen grammes of the extract per diem for three days, experienced very severe palpitations. Other experiments have proved to him that these dangerous effects were not attributable to the creatine and other nitrogenous principles of the extract, but to the salts of potash, of which it contains about one-third of its weight. In small quantities these salts have a beneficial action upon the digestion, and promote the circulation of the blood, but in larger doses they bring about paralysis of the heart. Many doctors can certify to the ill effects consequent on an abuse of the extract of meat. The right quantity to use is two and a half grammes for a basin of soup, and five grammes, or a dessert spoonful, per diem. Secondly, it is not an aliment. The same experimenter fed two young dogs of the same age, one with pure water, and the other with water containing five grammes of extract. To his great astonishment the dog fed upon the extract died on the twelfth day much wasted, while the other was still very lively. He attributes this effect to the salts of potash, which hastened the action of denutrition.

Liebig himself admitted that the extract alone was not an aliment, and chemistry has arrived at the same conclusion, since the nitrogenous principles of the extract at a degree of oxidation are higher than those which form animal tissues, and it is well known that our organs are meant to oxidize and not to reduce the principles furnished by digestion. Moreover, the creatine, which is the principal nitrogenous element of the extract, is a crystallizable substance, organic but not organized, and this latter seems to be the only substance proper to reconstitute our tissues. But the extract of meat decidedly possesses an agreeable flavor—that of good bouillon; this taste sharpens our organs and excites the stomach to act upon the other aliments. This is precisely that which constitutes a condiment; that is to say, a substance which facilitates the utilization by the stomach of other really alimentary substances. The same author has proved this by new trials. Two dogs were fed with meat which had been boiled and strained; to one was given half the meat, to which was added a corresponding quantity of extract, whilst a little salt only was added to that of the other. The dog fed upon the extract fattened rapidly, while the other became lean. These effects could be produced at will on the one dog or the other, by changing their food. The substitution of mineral salts for the extract gave nearly the same results, and shows the importance of the salts of potash in this product. The conclusion to be drawn from these experiments and others, which have led to the same results, is that the extract of meat is not a real food, but a precious aid to digestion and to the whole system. If the quantity of five grammes per day be not exceeded, it possesses over other stimulants, such as coffee and alcohol, the advantages of favoring nutrition, by facilitating the digestion of other food, and it is thus a valuable substance for convalescents, or persons weakened by chronic illness. As for its economical use, it is always restricted to the preparation of soup when butchers' meat is difficult to procure; and also in those cases where there is no time to cook meat; and under this last head it is to be hoped that it will in time come into use by our laboring population, in whose kitchens the time and the knowledge necessary in the preparation of a good soup, or *pot-au-feu*, are often wanting.

According to Pettenkoffer, the air in our houses becomes unwholesome when the carbonic acid in it, provided it be derived from the respiration of animals, rises from the normal proportion of 4 parts in 10,000 to 1 part in 1,000. The experiments of Dr. Angus Smith and Dr. Hammond have shown that the organic matter in the air, which increases in proportion to the amount of carbonic acid, is by far a more deadly impurity than the gas.

Putrid blood injected into the veins of a living animal is not mortal unless several drops are used; but the blood of an animal thus poisoned causes death in less than two days, in each minute quantities as a trillionth of a drop.

LAUGHTER AS A MEDICINE.—A short time since, two individuals were lying in one room, very sick, one with brain fever, and the other with an aggravated case of the mumps. They were so low that watchers were needed every night, and it was thought doubtful if the one sick of fever could recover. A gentleman was engaged to watch over night, his duty being to wake the nurse whenever it became necessary to administer medicine. In the course of the night both watcher and nurse fell asleep. The man with the mumps lay watching the clock, and saw that it was time to give the fever patient his potion. He was unable to speak aloud, or move any portion of his body except his arms, but, seizing a pillow, he managed to strike the watcher in the face with it. Thus suddenly awakened, the watcher sprang from his seat, falling to the floor, and awakened both the nurse and fever patient. The incident struck the sick men as very ludicrous, and they laughed heartily at it for some fifteen or twenty minutes. When the doctor came in the morning he found his patients vastly improved; said he never knew so sudden a turn for the better, and now both are up and well. Who says laughter is not the best of medicines? And this reminds the writer of another case. A gentleman was suffering from an ulceration in the throat, which at length became so swollen that his life was despaired of. His household came to the bed to bid him farewell. Each individual shook hands with the dying man, and then went away weeping. Last of all came a pet ape, and shaking the man's hand, went away also with its hands over its eyes. It was so ludicrous a sight that the patient was forced to laugh, and laughed so heartily that the ulcer broke, and his life was saved.—*The Sanitarian*.

HYGIENE OF DWELLINGS.—Remarkable testimony as to the permeability of the ground, and of the foundations of our houses, has been given by gas emanations into houses which had no gas laid on. I know cases where persons were poisoned and killed by gas which had to travel for twenty feet under the street, and then through the foundations, cellar-vents and flooring of the ground-floor rooms. As these kinds of accidents happened only in winter, they have been brought forward as a proof that the frozen soil did not allow the gas to escape straight upwards, but drove it into the house. I have told you already why I take frozen soil to be more air tight than when not frozen.

In such cases the penetration of gas into the houses is facilitated by the current in the ground-air caused by the house.

The house being warmer inside than the external air, acts like a heated chimney on its surroundings, and chiefly on the ground upon which it stands and the air therein, which we will call the ground-air.

The movement of gas through the ground into the house may give no warning that the ground-air is in continual intercourse with our houses, and may become the introducer of many kinds of lodgers. These lodgers may either be found out, or cause injury at once, like gas; or they may, without betraying their presence in any way, become enemies, or associate themselves with other injurious elements, and increase their activity. The evil resulting therefrom continues till the store of these creatures of the ground-air is consumed. Our senses may remain unawares of noxious things which we take in, in one shape or another, through air, water or food.—*Pettenkoffer, Sanitarian for May*.

EUCALYPTUS AS AN ANTI-MIASMATIC.—If the statements made in the journals and newspapers of America and Europe, in regard to the influence of the eucalyptus in preventing malarious disease, are to be relied on, there is no longer any occasion for the human family to be afflicted with diseases of that character. An excellent opportunity of putting the question to the test is afforded in California, where there are many districts esteemed malarious, which are remarkably well adapted to the growth of the tree. Indeed there is scarcely a locality on this coast where the tree would not grow. It is easily cultivated and its growth is remarkably rapid. The trees which have been planted about the dwellings, amid the ancient oaks of Oakland and Alameda, and which are only six or seven years old, already tower up above the surrounding forest and at a distance look like so many lofty steeples. Apart from sanitary considerations, there are many inducements to plant the eucalyptus over the valleys and plains of the Pacific slope. Not to mention the relief they would afford to the eye of the beholder, they would give shelter to cattle, protect the earth from the parching sun, supply a source of lumber and fuel, and possibly modify the climate and invite rain to some valleys now almost uninhabitable for want of it.—*Pacific Medical and Surgical Journal*.

LIME WATER FOR WASP STINGS.—Dr. Darnville writes to a French journal that some time ago he was stung on the head and face by a number of wasps. The pain was great, and he had no ammonia at hand, nor was there a drugget near by. Recollecting the fact that lime water was good for burns, it occurred to him to try it for the relief of the burning sensation produced by the stings. It answered the purpose perfectly, and he has since advised its use in some twenty cases of wasp stings, and it has always caused an instant cessation of the pain. The remedy is a simple one, and worth "making a note of."

USEFUL INFORMATION.

How Chromos are Made.

Chromo-lithography is the art of printing pictures from stone, in colors. The stone used is a species of limestone, found in Bavaria, which is wrought into thick slabs, with finely polished surface. The drawing is made upon the slab with a kind of colored soap, which adheres to the stone, and after the application of certain acids and gums, enters into chemical combination with it. When the drawing is completed, the slab is put on the press and carefully dampened with a sponge. The oil color, or ink, is then applied with a common printer's roller. The parts of the slab which contain no drawing, being wet, resist the ink, while the drawing itself, being oily, repels the water, but retains the color applied.

In a chromo, the first proof is a light ground-tint, covering nearly all the surface. It has only a faint, shadowy resemblance to the completed picture. The next proof, from the second stone, contains all the shades of another color. This process is repeated again and again, occasionally as often as thirty times. The number of impressions does not necessarily indicate the number of colors in a painting, as the colors and tints are greatly multiplied by combinations created in the process of printing one over the other. In twenty-five impressions, a hundred distinct shades may sometimes be produced. The last impression is made by an engraved stone, which produces that resemblance to canvas noticeable in all the finer chromos.

The production of a chromo, if it is at all complicated, requires several months, sometimes several years, of careful preparation. At every stage of the process equally great skill and judgment are required. The mere drawing of the different and detached parts on so many stones is of itself a work that requires an amount of labor and a degree of skill which, to a person unfamiliar with the process, appears incredible. Still more difficult, and requiring still greater skill, is the process of coloring. This demands a knowledge which artists have hitherto almost exclusively monopolized, and in addition to it the practical familiarity of a printer with mechanical details. "Drying" and "registering" are as important branches of the art as drawing and coloring. On proper registering the entire possibility of producing a picture at every stage of the progress depends. Registering is that part of a pressman's work which consists in so arranging the paper in the press that it shall receive the impression on exactly the same spot on every sheet. The difference of a hair's breadth would spoil a picture, for it would hopelessly mix the colors.

The paper used is white, heavy "plate paper," of the best quality, which has to pass through a heavy press, sheet by sheet, before its surface is fit to receive an impression.

After the chromo has passed through the press it is embossed and varnished, and then put up for the market. These final processes are for the purpose of breaking the glossy light, and of softening the hard outlines which the picture receives from the stone. These processes impart to it the appearance of a painting on canvas.—*N. Y. Tribune*.

Household Hints.

At this season of the year it is important for all householders to be on their guard against the insidious attempts of the various species of ants and the detestable cockroaches to invade the kitchen and pantries or store rooms. Sprigs of wintergreen will make the small red ants leave their cherished haunts. Borax powdered and put into the crevices where cockroaches abide will finally cause them to disappear, but we have found concentrated lye melted into a sort of paste and applied with a knife a more expeditious mode of destroying these noxious insects. Scalding alum water is also certain death to cockroaches.

To take stains out of mattresses, apply a paste of soft soap and starch over the spots, and wash it in with a damp sponge; if not clean at first, put on another paste, and repeat this until the spots disappear.

Most householders have felt the need of a receipt for mending knives, or rather for fastening knives and forks to their handles. The following mixture is recommended for this purpose in the *Scientific American*: Mix together one pound of rosin and eight ounces of sulphur, and keep it either in bare or reduced to powder; mix one part of this powder with half a part of iron filings, fine sand or brickdust, and the cavity of the handle is to be filled with this mixture. Heat the stem of the knife or fork and insert it hot, and when cold it will be found tight.—*Ec*.

SULPHIDE OF CADMIUM FOR COLORING SOAP.—The coloring power of the above mentioned material is so great that its price is of little importance. It is, however, frequently adulterated with zinc white, which may be readily discovered by digesting the suspected substance in acetic acid, filtering, and adding a solution of carbonate of soda, which produces a white precipitate if zinc be present.—*Sc. Am.*

There is a piece of track on the Kansas Pacific railway that is 30 miles long without a curve, and no grade that is more than three feet to the mile. The light of an engine can be seen for a distance of 14 miles on this strip.

Looking Into Death's Eyes.

The power of the eye is most strikingly illustrated by the fact that when two bodies of infantry meet in a charge of bayonets, the front rank on one side or the other almost invariably gives way directly the bayonets are crossed; that is before the cold steel enters the body of either party. The front ranks give way, the rear ranks are generally broken, and a rout ensues. The dreadful passion and fixed resolve in the front rank on one side overpowers that of their antagonists, whose hearts fail before them. Calculations have been made to supersede this, by the order that each soldier's bayonet shall not take the man directly in front of him in the enemy's ranks, but the next man to the left. A systematic mutuality of reliance was thus provided, and the effect of the enemy's eyes unspersed. It was a horribly clever idea. But in vain; the eye of the weaker will only shimmer, and wavers between the two—trembles for the man who gives the preference to the man whose bayonet point is within a few inches of the *juste milieu*. Between the two he generally falls or takes to flight. The single minded glare of the devil of war reflects the perfidious horror of the cold steel point. It is remarkable, on examining the dead bodies on a field of battle, after there has been a successful charge of bayonets, how few have been killed by the point in charging thrusts. The men have died from thrusts during flight, or from the clubbed, i. e. butt-end blows, or have been pierced when on the ground, or trampled to death.

How to Soften Hard Putty.

It is well known that the common putty, with which glass window panes are fixed in their frames, is made of powdered chalk and linseed oil. When old, it becomes so hard that, in case its removal is necessary, a chisel and hammer must be resorted to. In fact, it becomes like a stone, harder than the wood itself, pieces of which often break off unless peculiar care is taken in removing the putty. This hardness becomes a serious inconvenience when a large pane, say of valuable plate-glass, has to be removed for the purpose of repairs in the wood-work, or for some other cause. Here the use of chisel and hammer on the putty surrounding the glass may cause serious damage along the edges, or even total fracture. An agent to soften the putty in such cases, so that it may be removed with ease, is, therefore, of some value. This may be effected with a paste of caustic potassa, easily prepared by mixing the caustic alkali, or even carbonate of potash or soda, with equal parts of freshly burnt quicklime, which has previously been sprinkled with water, so as to cause it to fall into powder. This mixture is then mixed with water to a paste, and this is spread on the putty to be softened. Where one application is not sufficient, it is repeated. In order to prevent the paste from drying too quickly, it is well to mix it with less water, adding some soft-soap instead.—*Am. Homestead*.

GALVANIZED IRON.—The zinc in galvanized iron exists in two states. The state which constitutes its value is that of an actual alloy with the iron, but besides there remains a considerable quantity of zinc which is merely adherent mechanically. A method has long been required for ascertaining with facility, and a certain degree of accuracy, the extent to which the zinc has combined with the iron, and if this combination is perfect throughout the plate. Mr. T. Bruce Warren has recently discovered a mode effecting this desideratum. When mercury is rubbed over a perfectly galvanized iron plate, it adheres nowhere; but if part of the zinc is merely mechanically attached, in that place the mercury forms an amalgam with it and attaches itself firmly. To estimate the exact amount of zinc combined with the iron, Mr. Warren detaches a sample from the particular set of plates or wires to be tested, cleanses it with dilute sulphuric acid, and then immerses it from four to eight hours in mercury. The difference between the weights before and after immersion will be the amount of uncombined zinc. The piece is then heated in a deoxidizing flame, and the weight once more taken; the amount lost will, in this case, represent the quantity of zinc which was actually alloyed with the iron.—*Ec*.

IMITATIONS OF LEATHER.—A process has recently been introduced by which paper and cloth, or either of these materials separately, are prepared so as to answer in many cases as a valuable substitute for leather, not only possessing the color and appearance of the latter, but being proof, for all practical purposes, against injury from water, perspiration or moisture, the same as leather.

In this process the cloth or paper is first covered upon one or both of its surfaces with lithographic ink, corresponding in color to that of the leather intended to be imitated. The lithographic ink is applied to the surface of a stone, and the material to be prepared is placed upon this stone and subjected to the ordinary transfer operation of a lithographic press. The material being now removed from the stone, and the inky surface allowed to dry, a coating of shellac varnish, or other effective water-proof substance is applied to both sides. A superior article is made by applying a series of coats of lithographic ink, one after another, waiting for each successive coat to dry. In this way, morocco, or sheepskin, either green, blue, black or red, is almost perfectly imitated in external appearance.

THE SACRAMENTO SMELTING WORKS.—Two of the representatives of the new smelting works in Sacramento, who went to the Utah mining district to purchase ore, returned on Saturday, and report that on account of the severity of the past winter in Utah the season is about four weeks late, and none of the miners had ores ready for delivery yet. They made such arrangements, however, as will give them a full supply of ores in about a month, and then the smelting works will be put in operation and kept steadily at work.

CARSON MINT.—The following shows the business of the U. S. mint at Carson, Nev., during April, 1874:

	Ounces.	Value.
Deposits of gold.....	18,191.684	\$245,612.71
Deposits of silver.....	230,247.045	267,145.27
Total deposits.....	248,438.729	\$512,758.98
Coinage executed and bars manufactured.....		\$475,774.97

TOUR ROUND THE WORLD.—Professor J. D. Whitney, formerly of the California Geological Survey, is about to start on a tour round the world. He has come east with his family, and will sail for Europe about the first of June. —*Boston Globe*, May 5th.

THE clean-up of the Tuolumne hydraulic mine, formerly the Ronch and Ready claim, in Table mountain, last Saturday, after fifteen days' work at an expense of \$400 for labor, resulted in \$2,000.

PLACER mines have been discovered on the headwaters of the Bruneau river, Elko county, Nevada, about 70 miles northeast of Elko. They are only "Chinese diggings."

THE bad condition of the roads in Little Cottonwood cañon prevents the shipment of much ore from the mines.

A PROSPECTION season is expected in Cherry Creek district. Some of the ore from leading mines is very rich.

The Burleigh Drill and Air-Compressor.

It is only within the past two years that the Burleigh rock drill has been in use on this coast, and only during the past year that it has become so favorably known among us. There was of course some prejudice against these machines among the common miners, who imagined that their places would be declared vacant in favor of machinery. Like all labor-saving machines however, when really practical, these drills are now coming into very general use. The first place they were put in operation on this coast was at the Yellow Jacket mine, Gold Hill, and the favorable results attained there induced the Belcher mine to adopt them also, and now quite a number of mines are using them.

At the Yellow Jacket mine in Nevada, they are using one No. 3 pump, and one 5x12 engine, run by a No. 2 air-compressor. At the Belcher they have four drills also, two mining and two stopping, run by a No. 4 compressor. This same compressor runs two 7x12 engines which hoist about 100 tons of ore per day from the lower part of the mine. At the Gould & Curry they have two mining and two stopping drills and one double-gear 7½x8 engine which are run by a No. 4 compressor. In the Consolidated Virginia mine they have two stopping drills. At this mine they are now engaged in putting up a building in which to set a Burleigh air-compressor. This compressor will furnish air for running a 25-horse power engine in the lower levels—wherever it may be required—and also several Burleigh drills. The compressed air now used in the mine for running drills is brought in a pipe all the way from the Gould & Curry works. The Overman has a No. 3 compressor and two mining drills. In the Sutor tunnel they are using 22 of these drills and 12 more have been ordered. Some of these are mining, some stopping, and some jumper drills. They use a No. 3 air-compressor to drive the drills.

In California, the Mariposa Mining Co. are using one mining and two tunnel drills with two No. 2 and one No. 4 compressor. At the Gold Run Ditch and Mining Co. they are using three tunnel and one mining drill and a No. 2 compressor. At the Cedar Creek Mining and Water Co. in Placer county, they have a No. 2 compressor and two mining and one tunnel drills. At the Idaho mine, Grase Valley, they have a No. 4 compressor, and four mining drills have recently been shipped there. At the Little Emma tunnel in Utah, two mining drills are in operation, and they have sent for three stopping drills.

Many of these companies have duplicated their orders, showing that the machines give satisfaction. In tunneling at the Gold Run Ditch and Mining Company's property by hand, the average progress was less than five feet per week, and with the use of these air-compressors and drills the progress was increased to from 25 to 30 feet per week, and that at a reduced cost. At the Cedar Creek Co.'s tunnel at Dutch Flat, they are running a flume tunnel under the hill to tap the immense beds of gravel 2,900 feet in. The rock in Dutch Flat has always been known to be very hard, the men in many cases having been paid from \$60 to \$100 per foot to run a small tunnel 5x5 for a four-foot flume. With the aid of one of these machine drills they are now progressing at the rate of 25 feet per week, and in this case will soon be able to run the flume in to commence working from their first shaft.

MINING PIPES.—E. C. Ross & Co. are manufacturing six miles of twenty-two inch iron pipe for the North Fork Mining Company, at Dutch Hill, Plumas county, for the conveyance of water from the Feather river to the mine. The *Appeal* says that this is the largest job of the kind ever undertaken in this State, and involves an expenditure of \$80,000. This line of pipe will require 320 tons of iron, which will fill thirty-two freight cars. The iron is loaded on the cars at Pittsburgh, Pa., and the freight on the same will amount to about \$9,000.

MINING ACCIDENT NEAR SEATTLE.—On the 7th inst., an accident occurred at the Renton coal mine, near Seattle, resulting in the death of Andrew McKeckney, Superintendent of the mine. McKeckney was engaged in nailing down a strip of iron upon the railway in the main tunnel, when a loaded car broke from its fastenings and came down upon him, bearing him against another car and passing over his body, crushing his skull and body.

SMELTING WORKS IN SAN JUAN.—About 60 of the mining companies in San Juan district offer from five to ten tons of ore each, of a specified value, to assist any one erecting a smelting furnace of not less than ten tons capacity, in that district. The ore is to be furnished on the dumps of each mine as soon as the furnace is erected.

RICH.—The Salt Lake *Tribune* states that two tons of ore from the Mono mine recently sold for over \$14,000 per ton. That sounds like the assays from new discoveries in new districts.

ICE CONSUMPTION.—The consumption of ice by the men employed in the Belcher mine amounts to over 1,500,000 pounds annually.

Proposed Extension of Time for Necessary Work on Claims.

We have frequently called attention of late to the fact that if the necessary amount of work required by law was not done in mining claims by the 10th of June, 1874, said claims would be open to relocation, the same as new discoveries. It is now proposed to extend this time for one year from the 10th of June, viz., to the 10th of June, 1875. The original law of May 10th, 1872, provided that on each claim located after the passage of the Act until a patent was issued for it, not less than \$100 worth of labor should be performed or improvements made each year. On all claims located prior to the passage of the Act \$10 worth of labor must be performed or improvements made each year for each one hundred feet along the vein.

On the 1st of March, 1873, an amendment to the original act was approved, which extended the time from the first annual expenditure or claims located prior to the passage of the act, to the tenth day of June, 1874. As this date is nearly at hand, in many cases the miners have done, or commenced to do the work as required by law. Others, however, will probably wait until the last day before commencing work.

A bill is now being considered by the committee on mines and mining in Congress, which extends this time for the first annual expenditure for one year. It is as follows:

A BILL to amend an Act approved March first, eighteen hundred and seventy-three, amendatory of the Act entitled "An Act to promote the mineral resources of the United States," passed May tenth, eighteen hundred and seventy-four.

Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled, That the Act approved March first, eighteen hundred and seventy-three, amendatory to the fifth section of the Act entitled "An Act to promote the mineral resources of the United States," passed May tenth, eighteen hundred and seventy-two, which requires expenditures of labor and improvements on claims located prior to the passage of said Act, is hereby so amended that the time for the first annual expenditure on claims located prior to the passage of said Act, shall be extended to the tenth day of June, eighteen hundred and seventy-five.

This bill has not yet become a law, but some action will probably be taken upon it immediately, in view of its importance.

THE MINING BILLS IN CONGRESS.—Senator Sargent thinks that the action changing the reference of the mining bills in Congress from the committee on mines and mining, to the committee on the judiciary, is improper. He asked consent to submit a few remarks on the reference of the bill and said: I shall not detain the Senate long, especially as the question is not now debatable. I will say, however, that in my judgment the only question raised is a question of policy and not of law. All this legislation originated with the mining committee of the respective Houses, and those committees are peculiarly fitted by their constitution, by their knowledge of this subject and the experience of some of their members, to pass on the question. On consideration by the committee, however, it has been ordered that the subject be referred to the committee on the judiciary. I can only hope that the committee on the judiciary will look at the policy of the measure as well as at any question of law which may be suggested.

NEW MINES.—The Winnemucca *Register* states that old Gilbert, the veteran prospector, has struck it at last. For over four years he has been working alone on the eastern slope of Table Mountain, 60 miles south of this place, and we are pleased to know that his perseverance and untiring energy have at last been crowned with success. John Guthrie, who is interested in the mine, brought to our office, last Thursday, a large specimen of the ore, which is a mass of black sulphurets and horn silver. Five hundred pounds of the ore was sent to Austin last week, and the millmen who worked it returned Mr. Gilbert a net profit of \$400. The ledge proper is about four feet wide. The mineral stratum from which the specimen above referred to was obtained is about twenty inches wide. As is usual in all such cases, when it became known that a rich strike had been made, everything resembling quartz, for miles in all directions, was at once located. We are told that this new district is abundantly supplied with wood and water.

It is rumored in the city of Los Angeles that the Southern Pacific Railroad Company will, at an early day, commence the erection of machine shops on the ground near where the track crosses the Los Angeles river, in the eastern part of the city.

The stakes for the Los Angeles and Truxton Railroad are planted and negotiations for grading the road-bed are progressing. The Los Angeles press is rejoicing in the prospect that before many months that city will have two railroads to tide-water.

RUMOR has it that some good new placers have recently been discovered near the Japa camp, in Lower California. Some of the miners have made from five to fifteen dollars per day. A good deal of coarse gold is found.

MINING has commenced in good earnest at the Yakima mines, and some men have started up the river in a canoe to prospect the bars and creeks putting in above the Swauk.

Quicksilver Discoveries.

The high price of quicksilver within the past few months has had the effect of encouraging prospecting to a wonderful degree, and from all quarters of the Coast Range we hear of new discoveries of cinnabar ore. The hills are covered with prospectors, and claims are being staked off in all directions. Unfortunately, however, capital to develop these claims is not so abundant as the claims themselves. The prospectors are mostly poor men, who hope to dispose of their discoveries to parties able to develop the same into paying properties. Mines of this character are even more uncertain than quartz, which fact works against prospectors, for they must be able to show more than a simple hole in the ground and a few boulders of cinnabar, to induce moneyed men to pay them any attention.

If one out of ten of these quicksilver mines recently discovered should turn out to be really good mines, and have proper reduction works erected upon them, the price of quicksilver would rapidly decline. As it is, however, very few of them have as yet produced enough quicksilver to have any effect on the market.

Some of the new quicksilver mines are, however, being disposed of, and although the prices are not "fancy," they are sufficiently remunerative for prospectors. Extracts from the County Records, of Napa county, for last week, show the following sales of this class of property:

May 5th.—T. Dye to J. M. Davis, "Nancy" quicksilver ledge, near Mountain Mill House, Napa county—\$1,000.

May 5th.—J. H. Kellogg to J. M. Davis, "Blacksmith" quicksilver ledge, near Mountain Mill House, Napa county—\$1,000.

May 5th.—J. W. Brown to J. M. Davis, "St. Joe" quicksilver ledge, near Mountain Mill House, Napa county—\$1,000.

May 5th.—William Amesbury to J. M. Davis, "Dacotah" quicksilver ledge, near Mountain Mill House, Napa county—\$1,000.

E. T. Armstrong and T. N. Spencer to J. M. Davis, "Lizzie" quicksilver mine, near Mountain Mill House, Napa county—\$2,000.

A correspondent of the *Napa Reporter* states that Mrs. Rahlwing is about to sell her interest in the Bella Union mine for \$15,000, a much larger price than any of the others. The sale is not yet consummated however.

The *Colusa Sun* says: We learn that matters are assuming a lively appearance in the Coast Range. The quicksilver excitement continues to increase, and the indications prove of the most satisfactory character. A stage line has been placed in regular operation, between Colusa and Allen and Bartlett springs, which is receiving a very liberal support both in the way of passengers and freight.

The attention of our readers is called to a letter in another column describing the quicksilver mines of Cambria, San Luis Obispo county. These mines are new and but little is known about them.

Another article in another column gives the details of the discovery of extensive deposits of quicksilver at the sulphur banks in Lake county. The new company to work these mines expects to be in working order by September.

Cinnabar discoveries have recently been made in Fresno county, near Cerro Bonito, and work is being done on some of the claims.

STICKEN MINES.—The steamer Isabel, says the *Tacoma Tribune* of the 31st ult., sailed from Victoria on her first trip to Wrangel, the little boat being freighted down almost beneath the water's edge. She carried up 137 passengers, 130 tons freight, 16 mules and 12 horses, bound for Cassiar. The Otter is not yet down from the north, and there is no news from the mines. All the boats to run on the Sticken have gone except the Hope, and she will start in another day or two. Victoria steamers, boarding-house keepers and merchants are doing a rushing business, occasioned by this excitement, and the town has lost its entire floating population.

LABOR VS. MACHINERY.—The Mexican miners at Pachuca have attempted to burn the buildings of the New Barron mine because of the introduction of machinery by Mr. Barron, the ignorant natives believing that it would deprive them of the means of earning a livelihood in the future. Probably the men who carried the ore up from the mine in sacks strapped on their backs were afraid the hoisting works would leave them in want of a job. As foreigners become interested in these Mexican mines, however, the old fashioned customs will have to give way to improved machinery and methods of working.

At four o'clock in the afternoon on the 9th, 350 kegs of eastern powder were fired in the Enterprise claim, at Sucker Flat, which prepared an immense amount of gravel for washing purposes. One day this week 610 kegs of California powder were exploded in the Blue Point mine, which proved a great success.

OWING to some mistake made in the survey for the drifts running from the Consolidated Virginia, and the main south drift on the 1,300-ft. level of the Ophir, for purposes of ventilation, no connection has yet been made, and it is now thought that it will take until the first of the month to connect the two drifts.

Our Gravel Mines and Foreign Capital.

That English capitalists have been very much imposed upon, and often egregiously swindled in their mining ventures in the Pacific States, there can be no doubt. Nevada lead off as early as 1865 with her bogus silver mines, bleeding the Eastern cities as long as blood would flow; and Utah followed with her "salted" mines and false deposits, capping the climax with the gorgeous affair of the Emma, in which some of our leading men suffered somewhat in reputation for honesty, if they ever possessed any. This last affair was rather more than John Bull, with all his well-earned reputation for endurance in paying calls and writing for dividends, could stand. He tossed his burly head and uttered such a roar of rage and defiance that sent the mining harpies scampering in all directions. Many of these fellows were Americans, but they found willing and efficient helpers on the other side, who by their position and influence did more toward deceiving the British public than their American confederates. But whoever were to blame for these

Base Transactions

In some cases, and in others, when the intention of the vendors were good, but where all parties were deceived as to values, and in the more numerous instances where the property is really good, but the stock has been so fearfully "watered" as to leave but a small margin of profits to the shareholder, the disastrous results to the unquestionably good properties since offered in that market are all the same.

The foreign investors, smarting under their numerous and heavy losses in American mining ventures, fail to discriminate, and without due reflection set us down as sharpers, and our mines as bogus. Now, if they could be brought in reason on the actual state of facts, and calmly consider the situation, they would not be long in finding out their mistake, especially so with regard to California, which should not be confounded with Nevada, Utah, and the rest of the Pacific slope, as is the case with the people on the other side of the Atlantic. If these gentlemen would take the pains to investigate, they would find that their losses from

California Investments

Are exceedingly small, whatever they may have been in other localities of the United States. It is safe to assert that a very large majority of the companies organized abroad on the mines of California are paying better dividends than any of their home investments. This is more especially true with regard to our gravel mines held in England. Take for example the "Sweetland creek," "Birdseye creek," "Dutch Flat and Cedar creek," "Little York," "North America" and "Blue Tent." All of these are owned and operated by English companies, and all but the three last named are paying good dividends, even on their very large capitals, and for the current season promise much larger returns. The North America and Little York properties are known to be rich in the precious metal; and as the difficulties attending the first year of their operations under the new management have been overcome, it is confidently believed that a very prosperous year is before them.

The Blue Tent.

The last gravel mine placed on the London market, is considered by all who have seen it, inferior to no hydraulic mine in the State.

Having occasion to visit that section a few days since, the writer took pains to make a careful examination of it, and is forced to say that the property possesses, in the highest degree, every element of success. It is situated five miles northeast of Nevada City, and comprises an area of 600 acres of auriferous gravel, 500 acres of which are covered by United States patents. The great "Blue Lead," which traverses the State from north to south, is cut at this point by the South Yuba river, which now flows 500 feet below the old river bed. On the south bank of this stream, and occupying a bend of the river which sweeps around in a crescent for nearly one and one-half miles, lies the great gravel bed owned by the "Blue Tent Consolidated Hydraulic Gold Mines of California, Limited." From the river bluff the ridges rise very rapidly going south, until the south line of the property is reached, where the gravel is quite 1,000 feet in depth; and as the rim rock is visible on either side a distance of 3,500 feet apart, and as the extent of the claim along the channel is 5,000 feet, it is not difficult to estimate the number of cubic yards of gravel contained therein.

Professor Silliman, in his

Report on this Property.

Makes the following estimate: "Taking the gravel bed at 2,000 feet wide, by 4,900 feet long, and measuring 120 feet from the bed rock up for the blue strata, gives 43,555,555 cubic yards. The upper gravel above the zone of 120 feet may be safely stated at 350 feet deep, which would give 372,310,804 cubic yards, or a total of 415,866,359 cubic yards of gravel." In computing the value of the gray or upper gravel, he puts it at 10 cents per cubic yard, and for the lower or blue gravel, the value is placed at 50 cents. On this data the value of the Blue Tent property becomes as follows: 43,555,555 cubic yards at 50 cents, is \$21,777,777; 372,310,804 cubic yards of gray gravel at 10 cents per cubic yard, is \$37,231,080, or a total gross value of \$59,008,857. Deduct, he says, 25 per cent. for working, or \$14,752,214, which leaves a net value of \$44,256,643.

With regard to outlets, Mr. Geo. D. McLean, Superintendent of Sweetland Creek hydraulic mine, in a report on the property says: "The rim rock circles with the river, which latter forms mainly the north boundary of the property. Traversing at irregular intervals the precipitous slopes intervening, and connecting directly and indirectly the rim rock with the river, are Johnson's, Gopher, Cody, Sailor and Enterprise ravines. Owing to the sloping profile of the country, and the confluence of these ravines with the Yuba, the wealth of this deposit is laid open along its entire width for more than a mile upon the river, the receptacle of the debris. The washings are all situated towards the northern margin of the estate, so as to be readily available in sluicing the deep gorges or cañons mentioned tributary to the Yuba."

Water Supply.

The property possesses two ditches with a combined capacity of 800 inches of water for four months, a supply entirely inadequate to operate even one of their numerous outlets. But in order to supply this deficiency as far as possible, the company have arranged with the South Yuba Canal Company for a limited supply until their projected ditch is completed, and were recently using, in addition to their own, 1,500 inches of this water per day, at a cost of \$4,000 per month. At present there are only two outlets completed, but even with these double the present quantity could be advantageously used, and by opening other outlets the amount could be multiplied to many thousand inches, every additional inch increasing the yield of gold dust. In order to obtain

inches of water, under a pressure of 300 feet. The bank here is two hundred feet high, and yet the pipes are at work 200 feet above the bed-rock, the gravel being too deep to work advantageously in one "bench." The plan has been adopted to work off the surface to a depth of 250 or 300 feet, and to follow with another system of works down to the bed-rock. This will be done next year through a bed-rock tunnel, to be constructed from Enterprise ravine. It is estimated that there has been washed from the different claims comprising the property, up to the present time, about 6,000,000 cubic yards of ground, almost entirely from the gray or upper stratum, which gave a gross yield of \$800,000, or a little over 15 cents per cubic yard. The 37,000 cubic yards of blue gravel removed yielded \$10,100, or 28 cents per cubic yard.

A Chance for Capital.

Now, this magnificent prospect does not stand alone, but has numerous peers now in full operation in California, and hundreds more equally as valuable if the same amount of capital and enterprise were expended on them, to say nothing of the vast unwrought fields of the score of counties which form that grand gravel belt of California. This claim is merely cited as a representative mine of its class, and we invite our English cousins to reconsider hasty judgments and follow the example of their enterprising countrymen of the Blue Tent, by selecting properties of the same character, when there can be no risk if proper caution is used in the selection and judgment exercised in the management and direction afterwards.

READ'S ROAD-MAKING MACHINE.

an ample supply, a canal and reservoir system has been located, surveyed and a portion of the work already completed, and by the expenditure of some \$100,000 more 5,000 inches of additional water can be brought on the mine. The required funds, it is understood, are on hand in the London office, and the work will soon be vigorously prosecuted to completion.

Col. C. W. Tozer, the able and courteous superintendent, states that he expected to make very

Handsome Returns

To the shareholders this season. Notwithstanding all the disadvantages under which he has had to labor, in overhauling and rebuilding the works, constructing tunnels, laying flumes, etc., and paying out some \$30,000 for extra water, he says that if the funds for the construction of the new ditch had been placed in his hands early in the spring, the work would now have been completed, and the company realizing largely in excess of what they now are, besides saving the cost of extra water. Up to the time the present company became possessed of the property, in July last, it had been worked separately by the owners of the different claims, as well, perhaps, as it could have been done in segregated lots, and by men cramped for means to properly develop and supply their mines with water. But a marked change has taken place under the new management, which is shown by the extensive and substantial improvements on the premises; in fact, the energy and intelligence everywhere displayed evince the presence of a master-mind in the direction.

Improvements on the Claim.

Since Col. Tozer became superintendent he has expended some \$25,000 on the property. He has just completed a bedrock tunnel 400 feet long, seven feet wide, by seven feet high, leading from Sailor's ravine to the washings in the South Yuba claim. Here is being employed one of Fisher's hydraulic machines, which flows 750 inches of water under a pressure of 150 feet. From the mouth of the tunnel to the river there is a very complete and ingenious system of flumes, drops and undercurrents, the boxes being eight feet wide, and the undercurrents, of which there are four, are 36 feet long, 20 feet wide, the largest in use, with six falls or drops aggregating over 500 feet.

The Principal Works.

However, are on the Enterprise claim, some distance to the eastward of the South Yuba claim. Two of Fisher's and one of Craig's machines are in operation here, which use 1,500

The Stickeen Mines.

The Stickeen mines still continue to attract considerable attention. The reports from there continue to be contradictory, though they are mainly favorable. A citizen of Portland, recently from the Stickeen country, gives the following list of prices when he left the diggings: Flour is \$1 per pound; bacon, \$1.25; beans, \$1.25; coffee, \$3; tea, \$3; and no sugar for "love or money." Most of the miners have on hand a good stock of supplies—sufficient to last until the 1st of June. He left the mines on the 15th of April. The weather is warm and pleasant, and the grass two or three inches high at the latter place, and there is every indication of the continuance of a warm temperature. The snow is going away very fast on the southern sides of the various mountain ranges, and high water in the Stickeen river will make navigation more sure. Many claims are being located along Dease creek, the expense being \$2.50 for recording and \$5 for a miner's license. The creek claims are 100 feet in length and the width of the stream, be it what it may, where the claims are located. Land claims are 100 feet square. A man named Nelson, who went from Portland last winter, is making \$18 to \$25 per day, and can work but a few hours at a time.

As contradicting this report we give another which states the case differently. Mr. John Ladd, a resident of Portland, Oregon, has written to his wife from the Stickeen diggings, under date of April 11th and 13th, and the *Herald* has been permitted to make extracts therefrom. He says the weather is beautiful, but very cold. The ground is covered with snow about two feet deep, and beneath that it is frozen for a depth of from four to twenty feet. The beautiful valleys in which he was told he would find the diggings have all resolved themselves into a bleak and desolate plain of rocks, which are piled one above another in the most fantastic and astonishing forms. Mr. Ladd states that he has visited Thiebite creek, and after prospecting about for some time he returned to Dease's creek, where, with one hundred and fifty others, he is now prospecting for a claim. He says he has obtained prospects ranging from a few cents to as high as thirty-five cents to the pan, but he has not yet seen anything that would tempt him to remain in the country. Speaking of the extent of the mining camp, he simply refers to the fact of a large number of prospectors being scattered all over the country, and still no reports of discoveries of any kind reach the central camps. He does not think any really rich mines will ever be discovered so far north, as the shortness of the season will make the gold cost more than it is worth to take it out. The claims already being worked have an average of about two feet of pay dirt, with light stripping. In some places the pay gravel is covered with such a depth of earth that it will not pay the miners to delve after it. Mr. Ladd tells his friends not to think of starting to these mines, as they would undoubtedly live to regret it, and desires to warn all others that are in any way inclined to go thither. The river is fully open, and with the three steamers running to Buck's Bar, the miners from all parts of the coast will flock in and thoroughly test the value of these much-lauded mines.

Read's Road-Making and Ditching Machine.

We herewith present another California labor-saving machine, which we learn has been practically tested in several important counties in the State, and received the favorable opinion of all who have seen it work. The machine is adapted to all kinds of scraping—for turning roads whether on level or side hill ground, cutting ditches, leveling rivers (wherever scrapers can be used), and especially for leveling off land so as to allow of an equal flow of water for irrigation purposes. It may be operated with from six to eight horses, according to the work it has to do.

Our engraving gives an excellent view of the machine. By means of the two levers on either side of the seat in the rear, either end of the scraper can be raised to accommodate to the nature of the ground; while by another contrivance which will be readily seen, the scraper can be adjusted to any desired angle with the line of motion. When the scraper is working at an angle to the travel of the wagon, a side draft will be created, which requires to be counteracted. For this purpose the rear wheels are so constructed that the man who works the levers can crank the wheels to the right or left, to counteract the side draft, by the lever on the platform, with his feet, with perfect ease.

Gen. Bidwell was among the first to adopt its use. J. A. Klyser & J. G. Heald, of Cloverdale, road builders, are using the machine in Sonoma, Mendocino and Lake counties, for building wagon roads. W. L. Overhizer, of Stockton, an extensive farmer and prominent Granger, has secured the right for San Joaquin county for the purpose of building ditches and roads. The machines are manufactured by the Kimball Manufacturing Co. of this city, and sold by Wiester & Co., 17 New Montgomery street, to whom application can be made, for further information, either personally or by letter. R. F. Read, the inventor, is the traveling agent.

VISALIA BRANCH RAILROAD.—The Visalia Branch Railroad Committee, after waiting upon Mr. Stanford and obtaining his consent to connect at the Southern Pacific at any point most convenient to Visalia, have received subscriptions to the stock of the same, and announce \$50,000 taken already. This will undoubtedly secure the building of the road at an early day. The road will be about seven miles in length, and will probably be in operation within a few months.

LITTLE ROCK TOWNSHIP, Nevada county, is expected to make very large returns of gold this year. There is plenty of water and all the gravel mines are running full handed.

The river and harbor appropriation bill, as passed by the House, provides for extending the survey of the Sacramento river to Tehama, instead of Colusa, as originally provided.

A Rival for California and Australia.

The upper valley of the Madeira river contains, approximately, 400,000 square miles, marvelously rich in every product of the South America. Its eastern and central parts, the Bolivian provinces of Cordillera, Obiquitos, and the Beni, were first settled by the Jesuits, who penetrated northward from their settlements in the valley of the Rio de la Plata, and organized numerous "reductions" of the native tribes and founded many prosperous towns. These, however, were always either upon the banks of navigable streams or within easy reach of them. Lying in the extreme eastern part of the Madeira valley is the mineral Brazilian province of Matto Grosso, abounding in valuable agricultural products and gold and diamond washings. It is, owing to its inaccessibility, very thinly populated, but promises to be in the future one of the most prosperous States of the Empire of Brazil. It is also one of the, at the present, most unprotected frontiers of that country, being almost at the mercy of the States of the Plata valley in case of war. Ascending the upper central and western rivers of the Madeira valley, we reach the richest of all the slopes of the Andes, well populated by the Spanish race, mixed with Quichua and Aymara Indians; the Indian element being probably the best which can be found on the Western Continent, and capable of a high degree of civilization. Its power of increase is extraordinary, surpassing even that of the Mexican Indian races, which are so fecund. The Bolivian part of the Madeira valley contains about 2,500,000 people, the Indian blood slightly predominating. At the date of Bolivian independence, in 1825, the population was less than 1,000,000. Out of the present inhabitants some 2,000,000 are in the valley of which we treat, living within comparatively easy reach of the navigable streams which swell the volume of the river Madeira. The country in which they live is, without exception, the richest on the globe, in everything that nature gives to man. Its mineral wealth cannot be equalled within any equal area upon the Western Continent. The number of silver mines opened there during the rule of Spain might appear fabulous were they not registered in the archives of the State. They exceed 10,000. From the banks of the little streams which feed the Beni branch of the Madeira, gold may be washed almost anywhere; and we have little hesitation in stating that this auriferous district will yet rival, if not surpass, the fame of Australia and California combined. In fact, the whole slope of the Andes, in an immense sweep of 1,000 miles, extending from Cuzco to Matto-Grosso, is a vast gold placer.

THE LORRAINE BRICK.—The silver brick which is to be forwarded to Sir Lamhton Lorraine by citizens of this portion of Nevada, in testimony of their appreciation of his noble humanity in the Santiago de Cuba affair, is now completed and will be sent away as soon as a suitable box has been manufactured in which to ship it. The bricks weigh over fourteen pounds, Troy, and was purchased by contributions of one dollar each, made by citizens of this town, Gold Hill and Carson—no man being allowed to contribute over one dollar. The brick is very handsomely proportioned, pure and smooth. The upper surface is polished until it is as bright as a mirror, while the bottom and sides were left just as the bar was taken from the mould. The inscription, which is as follows, is engraved on the polished face in old English text and old-style Roman letter: "Blood is Thicker than Water. Santiago de Cuba, November, 1873. To Sir Lamhton Lorraine. From the Comstock mines, Virginia; Nevada, U. S. A." This inscription is surrounded by a neat ornamental border, which runs round the whole face of the brick. The brick was polished and engraved by M. M. Frederick, the well-known jeweller of this city, and a finer job could not have been done in any city in the Union. The lettering is most beautiful and perfect. The brick will be on exhibition in the window of Mr. Frederick's jewelry store for a day or two, pending the making of a suitable box in which to place it.—*Virginia Enterprise*.

PAYING OFF.—Several of our leading mining companies yesterday paid off their workmen, and, during the afternoon, there was to be seen marching into the Bank of California a regular procession of miners, each with his check in his hand. Coin will now be plentiful for a week or two. The employees of the Imperial and Yellow Jacket mining companies were paid off on Saturday last. The pay-roll of the Imperial company footed up \$15,000, and the Yellow Jacket \$12,000. The employees of the Crown Point Mining Company were paid off yesterday. The disbursements made by the company for the month of April amounted to \$80,000.—*Virginia Enterprise*.

GOLD BARS TO BE ISSUED.—The following is the full text of a bill which has passed the Senate and awaits the decision of the House: *Be it enacted, etc.,* That the Treasurer may from time to time transfer to the office of the Assistant Treasurer at New York, from the hullion fund of the assay office at New York, the refined gold bars bearing the United States stamp of fineness, weight and value, or bars from any mint offering gold coin or hullion of a standard equal or above that of the United States, and may apply the same to redemption of coin certificates, or in exchange for gold coin at not less than par, subject to such regulations as he may prescribe.

Mining Progress in Spain.

According to official reports published on the subject, there has of late been considerable progress in the mining industry of Spain. Thus, from the district of Gurracha (Melega), we learn that the exports of iron ore to England in 1872, amounted to 27,000 tons, against 2,000 tons in the preceding year. It is stated that there exist all along the coast great masses of rich ore, requiring little capital to convert them into profitable mines. Lead has also been largely exported, the production having much increased. The ore is raised by steam power, all the principal mines having imported small steam engines for that purpose, but the drainage of the whole is undertaken by a special company, and a central pumping engine draws, through the medium of subterranean communications, the water from all the mines. This, at a certain level, is also accomplished by means of a tunnel or adit driven through the mountain containing the ore, at the sea level. So abundant is the ore in this hill, that there are, in the part which is being worked, no less than 32 mines at present yielding mineral, many of them producing immense fortunes for their owners. About one-half of the mountain is said to be still virgin, and throughout the whole district, mining is susceptible of great improvement. The concessions of ground may be easily and cheaply procured, and properly worked, give the best hopes of profit. The ores are now smelted in clay blast furnaces of the rudest construction, with long condensation flues. Cupellation or extraction of the silver is not practised in the district, the very rich lead being sent to Carthagena to be desilverized. The exports of iron ores from all parts of Spain to the United Kingdom in the five years from 1868 to 1872, were as follows: 1868, 88,700 tons; 1869, 99,816; 1870, 170,085; 1871, 302,282; 1872, 631,134, thus showing a considerable augmentation. It is mentioned that the mines situate at El Rohledad (Melaga) are especially worthy of attention, as they contain the richest magnetic iron ore in the province. So highly magnetized are these ores, that it is stated a solid block some tons in weight, on being struck with a heavy hammer, immediately acquired extraordinary pole conditions, and the particles of iron about it, and within reach of its action, assumed upon it that peculiar hissing appearance, common to all powerful magnets.

IDAHO PLACERS.—A. J. Smith, who left this city a few weeks since, ostensibly for the purpose of paying a visit to the "land of Pike," now confesses that the trip he took was altogether of a different kind. He went to hunt some placer mines somewhere in the direction of Idaho, of which he had information. He found the mines all he had anticipated, made his location, and left two men to hold his claims and prospect further as the snow should disappear. At the time of his visit about four feet of snow covered the region about the mines. The gold is fine, the largest pieces being smaller than grains of blasting powder, but it is of good quality, being worth \$18 per ounce—such, at least, was the sample exhibited to us. We are informed, however, that specimens weighing two or three dollars have been found in the mines. The gravel prospects from four to seven cents to the pan on the surface, the deepest hole sunk by Mr. Smith being but four feet in depth. He has no idea how deep the ground may be, not having looked for the bed-rock. There is an abundance of water on the ground for either sluicing or working by hydraulic process; with plenty of fell and all else required for successful mining, except timber. The mines are in a timberless region, but little will be required, except lumber for sluices. The gravel deposit is described as being of a deep red color, like that seen in many places in California. The exact location of the mines is not made public, but Mr. Smith will shortly return to the diggings, and if they are all that he now believes them to be he will make known their whereabouts.—*Virginia Enterprise*, May 5th.

DEEP MINING.—Deep mining is necessarily becoming the rule in most of the older and many of the new mining districts. The deepest artesian boring in the world is that near Berlin, where the auger has been driven 1,270 meters. The discovery of rich deposits of silver in some Bohemian mines, has led to the deepening of the shaft to 1,200 meters, or 4,000 feet. This is a new disproof of the vague assertion that metalliferous veins give out in depth. But it is in coal mining that the greatest developments in deep working are now taking place. In Belgium the shafts descend 100 meters (330 feet) every 10 years, on the average, and individual mines, of course, are carried down more rapidly. One in Belgium is more than 3,000 feet deep. In some remarks before the Society for the Encouragement of Mineral Industry, in Paris, Prof. Gruner said that the extraction of coal throughout the world amounted to 240,000,000 tons yearly, which might be valued at 10 francs at the mine. This gives a total value for coal of \$480,000,000 (gold), while all other mining products taken together do not exceed \$320,000,000 in value.

HEAVY PLATE.—The largest plate that has been rolled in Scotland from a single pile was rolled at the Blackhairn Ironworks, Glasgow, lately. The dimensions are—23 feet six inches long, four feet wide, and one inch thick. The weight of pile going in the furnace was 4,400 pounds—nearly two tons,

Mining Suit.

The Mahogany Gold and Silver Mining Company have brought suit in the Fourth District Court against Henry G. Blankmen, Thomas J. Owens and Joseph B. Blankman. The company alleges that at a meeting of Board of Directors, held on the 9th of April last, at which were present O. H. Bogart and the defendants, H. G. Blankman and Owens, Owens advocated this purchase by the company of a large number of shares of the stock of the Challenge Mining Company, under pretence that the purchase would be advantageous and in his views he was supported by Blankmen, but they were opposed by Bogart. Cooper and Hull, also members of the Board, although not present, were well known to be opposed to the proposed purchase. The company charges that Owens and Blankmen were owners of a large number of shares of the stock, and had agreed to purchase, at a mere nominal price, a great number of shares in case they could sell the same to the company, through its Board of Directors, for a large price. Finding they could not procure the consent of the Board to the purchase of the stock, Blankman and Owens conspired to get possession of the books and papers, and to take pretended proceedings to remove Bogart from his office of President of the Board, and also from his office of trustee, and to put in the defendant, Joseph B. Blankman, a son of H. G. Blankmen, in his place (who it was well known would obey the wishes of his father).

Plaintiff further avers that Owens and H. G. Blankmen held a pretended meeting of the Board of Trustees; that the plaintiff had no knowledge of what transpired, except what is derived from entries made by Owens in the book of the Board, wherein it is stated that the office of trustee held by Bogart was declared vacant, J. B. Blankman elected in his place, and H. G. Blankman elected President. Subsequently the defendants took possession of the books, and a large amount of money belonging to the plaintiff; and on the 15th of April, pretending to act as trustees of the company, they made a contract to purchase for the company 7,725 shares of the stock of the Challenge Mining Company, at \$1.25 per share; that they took the sum of \$9,656.25 out of moneys belonging to the plaintiff, which they used in payment of the shares. The defendants then offered to surrender the possession and to resign their offices, provided the company would purchase of them 2,500 shares of the stock of the Challenge Mining Company; that in view of the injury to the business of the plaintiff, O. H. Bogart, the President, acceded to the proposal, but without authority from its Board of Trustees, and paid to defendants \$17,500, being the sum of seven dollars per share, and received certificates of stock for \$2,500 shares; that the market price of the stock at the time of the purchase was not to exceed five dollars per share. Thereupon the defendants delivered over to the company its books and moneys, except \$9,656.25, which was used in the pretended purchase of stock of the Challenge Mining Company. The company asks judgment for \$9,656.25 paid for stock, \$17,500 paid by Bogart, and for \$10,000 damages.

THE STICKEN MINES.—Mr. W. M. Vance, of this city, furnishes the *Call* with a letter from Julien Smith, a friend of his, dated Fort Wrangel, April 20th. The letter says: There is little known here about the mines, except that there were some good prospects got last fall; but there is nothing yet discovered to justify a big rush here. There are here end in the mines about 800 men, and that is more than enough for the present; and I would earnestly advise any one who thinks of coming here to wait till there is something more definitely known. From all I can learn, this is a very bad country to travel over. It is about 180 miles up the river to Buck's Bar, and the current, like all mountain streams, is very rapid; and for the present the only mode of getting up is by canoes. Then the trail is through brush and swamp for about eighty miles to Dease Lake. I will write again when I have looked through the mines.

PRICE OF WATER.—The miners up about Moore's Flat have struck for lower water and as a consequence times are rather dull up there at present. It seems that the Ditch company which supplies Moore's and Woolsey's Flats is still charging the old rates there—12½ cents an inch—though along the ridge, 20 miles and more below, they have reduced the price to eight cents, and the miners held a meeting on the 25th at which it was determined not to work the mines till the Ditch Co. will sell them water at the reduced rate. It is thought the miners will carry the day, as the North Bloomfield Co. agree to run a branch ditch in there if sufficient inducement is held out.—*Foot-hill Tidings*.

THE YELLOWSTONE PROSPECTORS.—An expedition of prospectors, which left Boseman, Montana, some time since, to explore the Yellowstone and Tongue river country, are reported by Captain Sweitzer, commanding at Fort Ellis, to be retreating up the Yellowstone, with frequent skirmishes with the Indians. They turned back near Tongue river, after a fight, and have reached a point about 195 miles from Fort Ellis. One man was killed and two wounded, and a considerable amount of stock was killed. A number of Indians are reported killed, and their stock captured.

The Transit of Venus.

This most important expedition that has ever been sent out by the United States is nearly ready to start, its object being the observation of the transit of Venus, which occurs on the 8th of December next. Eight parties are to be sent out from the United States, and, as above noted, arrangements have been completed to compare and exchange their results with the experiences and observations of the German, French, Russian and English expeditions. Three of the parties are to be established in the northern and five in the southern hemisphere. The observations are to be made at Wladivotok, in Siberia, under charge of Prof. Hall, of the Navy. Another party will proceed to Asia, and there they will divide. One party, under Professor Davidson, of the Coast Survey, is to make the observations at Nagasaki, Japan. The other, under Prof. Watson, of Ann Harbor, Michigan, will proceed to Peking, China, and there make their observations of the transit. The corps who are to observe the transit of Venus in the southern hemisphere are to sail from New York in the United States sloop-of-war *Suclara*.

This vessel has been docked at the Brooklyn Navy Yard, and is being thoroughly prepared for the long voyage she is to make. Her upper decks have been entirely rebuilt, and her guns taken ashore. On the upper, or spar-deck, eight large staterooms have been built, for the accommodation of the scientific gentlemen of the expedition. The after part on each side of the stern has been built out, making two large windows, and enlarging the Captain's room materially. Below, on the next deck, a ward-room pantry has been built under the Captain's room, and six fine, large staterooms have been built, on each side of the wardroom, for the accommodation of the *Suclara's* officers. A partition has been run across the vessel, dividing the wardroom from the steerage. On each side of the steerage five staterooms have been built, for the use of petty officers of the vessel. Still further forward is the berth-deck, where the men are to sling their hammocks and quarter.

After the *Suclara* sails from New York she will proceed first to Rio Janeiro, and making a short stay there, will cross to Cape Town. At Cape Town the last preparations for the comfort of the expedition will be made, and stores will be taken on board to last until the vessel reaches New Zealand. From Cape Town the *Suclara* will proceed to a group of islands called Crozette's Islands. There a party of observers, under Captain Raymond, of the Army Engineer Corps, are to be landed, and the *Suclara* will return for them on her home voyage.

From the Island of Desolation, Captain Chandler is to proceed to New Zealand, by way of Sydney. At Tasmania he will leave a party under Lieutenant Peters, United States Navy, to make observations of the transit and other scientific explorations. From Tasmania the *Suclara* will go to the Chatham Islands, in the Southern Indian Ocean, and there Captain Chandler will land another party under Professor Smith, of the Coast Survey.—*N. Y. Times*.

Colusa Quicksilver Mines.

The Colusa *Sun* has the following: From all we can learn, we are satisfied that the country round White Sulphur Springs is the richest in cinnabar of any district in the United States. Mr. Bartlett, an experienced miner, in a letter to us this week says: "There is great excitement here on account of recent discoveries made by Lovelace and Noble on the west side of Bear valley. They have found the richest prospect I ever saw. The ore will go from 20 to 30 per cent., and they say it came from the croppings. Mr. Caswell, of the Buckeye, was called upon to examine their discovery, and he reports very favorably. He had some four or five pounds of the ore that would assay some forty or fifty per cent. I start out soon on a prospecting tour. The Buckeye is the best mine in this part of the country. They are reckoning about two hundred pounds of quicksilver daily. The Ahhot mine is good, and I think the present company will make a good thing of it. The Chapin mine is also good. They intend putting up a furnace at this mine. They have enough ore in sight to pay for the work."

Cinnabar is being taken out of two tunnels in this mine, and they have out now about one hundred tons, estimated to yield ten to fifteen per cent. on the average. It is the intention of the company to put up a furnace in a short time. When the three furnaces now contemplated shall be in operation, we shall ship several thousand pounds of quicksilver daily from Colusa. And if the new discoveries prove as rich as indications warrant us in believing they will, several other furnaces will be put up during the summer.

GOLD AND SILVER.—One ton (2,000 pounds avoirdupois) of gold or silver contains 29,163 troy ounces, and therefore the value of a ton of pure gold is \$602,799.21, and a ton of silver, \$37,704.14. A cubic foot of pure gold weighs 1,218.75 pounds avoirdupois; a cubic foot of pure silver weighs 556.25 pounds avoirdupois; \$1,000,000 gold coin weighs 3,658.8 pounds avoirdupois; \$1,000,000 silver coin weighs 51,925.9 pounds avoirdupois. If there is one per cent. of gold or silver in one ton of ore, it contains 291.63 ounces troy, of either of these metals.

GRAND INDUSTRIAL EXHIBITION,

To be held under the auspices of the

MECHANICS' INSTITUTE OF SAN FRANCISCO, CALIFORNIA.

Opening on August 18th, 1874.

The Board of Managers herewith announces that a grand industrial fair will be held in the city of San Francisco for 30 days, opening on August 18, 1874.

In view of the increasing commercial and manufacturing importance of San Francisco, its contiguity to and close connection with the various countries bordering on the Pacific, the managers have constructed a Pavilion, having a floor area of 150,000 feet, and have invited to it all who are disposed to come and exhibit. All exhibitors will be placed on the same footing. Motive power will be furnished free.

The building will be open day and evening, and every facility will be extended to exhibitors and visitors.

Application for space must be made without delay to the Secretary of the Board of Managers, 27 Post street, San Francisco, and all inquiries will be answered and information extended promptly.

No space can be secured unless applied for before the 20th of July next. A. S. HALLIDIE, Pres.
13v28-3m J. H. CULVER, Sec'y.

The object of this school is to impart a thorough education in business affairs. It is open to persons of both sexes and of all ages. There is an English Department for those not sufficiently advanced for the Business Course. Sessions continue day and evening throughout the year. Students can enter at any time. All wishing to be successful should secure a practical education at this College. Send for "Heald's College Journal," and learn full particulars. Sent free to all by addressing E. P. HEALD, Pres. Business College, San Francisco, Cal.

BUY BARBER'S BIT BRACE.

The Quicksilver Mines of San Luis Obispo County.

EDITORS PRESS:—From time to time brief notices have been published concerning the mines in the San Simeon district, located near this place. These accounts have simply given the public to understand that there are deposits of cinnabar in this range of mountains, without specifying particularly either the locality or the extent of the mining region. Your correspondent came here for the purpose of looking at these mines, and after two days of laborious riding on horseback he is prepared to make a report.

The San Simeon District

Embraces an extensive tract of country lying in the coast range a few miles east of Cambria. None of the discoveries date farther back than three or four years, and all the developments have been made within the last two. It is remarkable that so much has been done and so little said about it. The best known claims in the district are on Pine mountain, thirteen miles northeast of this place in the range of mountains known as the Santa Lucia. It is a beautiful mountain, completely covered with immense forests of pine and oak, and distinct from the surrounding hills in this particular. Here are located two parallel ledges running north-west and southeast, dipping to the east on an angle of about 80°.

The Pine Mountain Company.

In July, 1871, Mr. O. Haskins, while looking for timber in this range, made the discovery of cinnabar. He was well acquainted with this character of ore and saw at once he had dropped on a good thing. He returned to Cambria, where a company was organized and arrangements made to prospect. This company took up 2,000 feet on the ledge and men were set to work drifting into it. Quantities of the ore were sent to Hewston and Garnett of San Francisco. The returns showed an assay of 6½ per cent. in quicksilver, which, of course, was highly satisfactory. This attracted the attention of parties in San Francisco, who took a bond on the claim for six months for the purpose of fully prospecting it. After expending two thousand dollars, the claim was abandoned and it reverted to the original locators. Since that time a shaft has been sunk on the ledge to a depth of 50 feet and an 80-foot drift run in on that level, developing a mine rich in cinnabar with an average width of 40 feet. The ledge is well defined, with regular walls of serpentine and talc. The matrix on top is of a yellowish cast, similar to that of the celebrated Almaden mine. On going down it becomes hard with spar feeders, running across the veins at regular intervals. These feeders in places are solid, blood-red metal. The company have a number of hands employed at present lifting ore from the lower drift, which is very rich. The principal owners are Haskins, Russell, Van Gordon, Layton, Forrester, Lingo, Palmer and Proctor of Cambria.

The Jeff Davis

Is the name of the adjoining claim on the same ledge. It has one chimney 80 feet in diameter, and exhibits abundance of good metal. Very little has been done to develop it. The claim embraces 1,600 feet. A company is running a tunnel in to tap the vein at a considerable depth, with good prospects.

The Santa Maria,

Located still farther north on the same ledge, is a claim of 1,200 feet. Here the ledge is mostly covered by a break in the hill. A drift 500 feet long will tap it at a depth of 300 feet.

The Gibson and Phillips.

This is a consolidation of claims of 3,200 feet, extending north on the same hill. The character of the ore is the same. This claim was recently bonded to J. M. Thompson, of San Francisco, for \$40,000. They have done considerable work here, developing an excellent mine with large quantities of pay ore in sight. The owner is now making arrangements for erecting furnaces on the ground. There are 2,000 tons of first-class rock on the dump ready for reduction. The above embrace all the locations on the Pine mountain ledge.

Eight hundred feet below on another ridge of mountains is the "Little Almaden." The principal claims here are the Phil. Sheridan, owned by Messrs. Brewster, Land & Head, of San Francisco, the Buckeye and the North Star, all of which show good metal. The Phil. Sheridan has 500 tons of pay ore on the dump.

Other Lodes.

About one mile south of Pine mountain, in the same range, and running parallel, are other lodes, the first of which is known as the Quien Sabe.

This mine has more and richer metal in sight in the croppings than any other in the whole district. It seems to be a solid mountain of metal. On the day of my visit it was raining, and the sight presented at this place was indeed wonderful. The hill for hundreds of feet was red with cinnabar. I have traveled over the entire mining regions of this coast and I never saw so much wealth lying exposed to the elements before. This is owned by a few poor men, who have managed to drive a tunnel in a long distance, at a depth of 400 feet from the croppings. Good metal is exposed along this tunnel for a distance of 220 feet. Large quantities of ore can be extracted here with little labor. This mine is for sale, but it will

take a fortune to purchase it, so confident are the owners of success.

The Todos Santos

Is an extension of the Quien Sabe, and looks extremely rich in cinnabar. It belongs to the claims recently located, and but little has been done to prove its value. The lode seems to be very wide and rich. Thousands of tons are exposed to sight in the chimneys and croppings. It is owned by a few individuals, some of whom belong here. It is easy of access, and work is now being prosecuted upon it vigorously. Parts of the ledge are a sort of conglomerate, while other portions are rich in metal. Cinnabar is even found in the pebbles that make up this conglomerate.

The Keystone.

Among the early locations made in this district is the lode known as the Keystone, one mile further south and still lower down. Cross & Co., of San Francisco, agents of English capitalists largely engaged in mining on this Coast, purchased this claim (1,200 feet) one year ago and have gone to work in dead earnest to prove its richness. A shaft has been sunk to a depth of 160 feet on an incline with the ledge, with satisfactory results, laying bare large bodies of metal and showing better as they advance. A tunnel 250 feet long taps this shaft. There are 500 feet of drifts in the mine in different parts of the ledge. Twenty miners are employed and the force will soon be much increased. The company has a furnace in course of construction whose capacity will be 20 tons per day. Large quantities of good ore are also on the dumps at this mine. The Home company's claim is considered a very excellent one, and joins the Keystone on the north. It is owned by Cambrians, who feel very sanguine over the prospects. They are too poor to put up reduction works and they hope to get capital interested.

All these mines lie due east of San Simeon bay, a distance of about seven miles. The altitude is 3,000 feet. A thousand pounds of surface ore on the Keystone ledge, worked by Jno. Roach, of San Francisco, yielded 53 pounds of pure quicksilver.

Recently, discoveries have been made at the head waters of Santa Rosa creek, six miles east of Cambria, which attract considerable attention just now; it is the same character of mineral as above described. The facilities for working these mines are unusually favorable. There is plenty of wood and water close by and they are all accessible.

The fact is, there is no estimating the extent of these deposits. It is a vast belt of mineral reaching for miles and miles, and a short time will demonstrate that the true wealth of San Luis Obispo county is not in its milch cows or pastures, but rather in the mineral sealed up in the granite vaults of the mountains, and ready to be extracted by the hard-handed miner, who will here find scope for his most exaggerated imaginings. The mines I have mentioned are only a few of the many discovered here, on which work is being prosecuted at present. There is, perhaps, no place on the coast that affords better chances for the prospector than this, or that promises surer returns for his labors. It has been wholly neglected by the press. Here is a new field for idle capital to operate in, with almost a certainty of large returns. Let it flow in and the world will soon hear of a new Eldorado.

ALSTON.

Cambria, San Luis Obispo county, May 18.

THE Tuolumne Democrat reports that the clean up of the Tuolumne Hydraulic mine, formerly the Rough and Ready claim in Table Mountain, last Saturday, after fifteen days' work at an expense of \$400 for labor, resulted in \$2,000 of the prettiest gold ever caught in a flume, and it costs over \$20 to the ounce.

A COPPER mine has been discovered near Unionville, Nevada.

THE Hoosac furnace has been started up again.

PATENTS & INVENTIONS

A Weekly List of U. S. Patents Issued to Pacific Coast Inventors.

[FROM OFFICIAL REPORTS FOR THE MINING AND SCIENTIFIC PRESS, DEWEY & CO., PUBLISHERS AND U. S. AND FOREIGN PATENT AGENTS.]

By Special Dispatch, Dated Washington, D. C., May 12, 1874.

FOR WEEK ENDING April 28, 1874.

LIFE BOAT AND SAFE.—Oliver C. Reid, S. F., Cal.

FARM GATE.—Ezra L. Brooks, Smith Ranch, Cal.

AIR COMPRESSOR.—Wm. H. Fauntleroy, Eureka, Nevada.

COTTON AND HAY PRESS.—Walter W. Inman, Lone Pine, Cal.

ORE-DRESSING APPARATUS.—Jas. Scrimgeour, Emma Mine, Utah.

BUNGS.—William Webster, S. F., Cal.

TRADE-MARK.

GRAIN BAGS.—Edington Detrick, S. F., Cal.

*The patents are not ready for delivery by the Patent Office until some 14 days after the date of issue.

NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & CO., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent licensees for Pacific coast inventors transacted with perfect security and in the shortest time possible.

METALS.

WEDNESDAY M., May 13, 1874.

Pig Iron is very much depressed. The general Metal market quiet. Quicksilver strong.

Scotch Pig Iron, 30 ton	\$42 50
White Pig, 30 ton	40 00
Refined Bar, had assortment, 30 lb	32 50
Refined Bar, good assortment, 30 lb	32 50
Boiler, No. 1 to 4	4 50
Plate, No. 5 to 9	5 50
Sheet, No. 10 to 13	5 50
Sheet, No. 14 to 20	5 50
Sheet, No. 24 to 30	5 50
Horse Shoes, per keg	8 00
Nail Rod	8 00
Norway Iron	8 00
Roller Iron	8 00
Other Irons for Blacksmiths, Miners, etc.	4 50

QUICKSILVER, per lb. 1 35

Brass, 30 lb	50
Copper, 30 lb	50
O. N. P. 30 lb	55
Sheathing, 30 lb	25
Sheathing, Yellow, 30 lb	25
Sheathing, Old Yellow	10 50
Composition Nails	25
Composition Bolts	25

LEATHER.

WEDNESDAY M., May 13, 1874.

Jointed Leathers are very scarce in New York and not over plentiful here. It is reported that some 2,000 cases of fine skins were lost in the French steamer *Europe*. Prices have consequently advanced east, and are still higher. Trade is much better than previously noted and now is comparatively active.

City Tanned Leather, 30 lb	25 00
San Cruz Leather, 30 lb	25 00
Country Leather, 30 lb	25 00
Stockton Leather, 30 lb	25 00
Jointed, 8 Kil, per doz	50 00
Jointed, 11 to 14 Kil, per doz	55 00
Jointed, second choice, 11 to 14 Kil, per doz	55 00
Cornellian, 12 to 16 Kil	57 00
Cornellian Females, 12 to 14 Kil	60 00
Cornellian, 14 to 16 Kil	65 00
Seamerville, 15 Kil	60 00
Simon, 18 Kil, per doz	61 00
Simon, 20 Kil, per doz	65 00
Simon, 24 Kil, per doz	72 00
Robert Calif, 1 and 9 Kil	25 00
French Kips, 30 lb	1 00
California Kip, per doz	40 00
French Sheep, all colors, per doz	8 00
Eastern Calf for Backs, 30 lb	1 00
Sheep Roams for Topping, all colors, per doz	9 00
Sheep Roams for Lining, per doz	5 50
California Russell Sheep Linings	1 75
Best Jointed Calf Boot Legs, per pair	5 00
Good French Calf Boot Legs, per pair	4 00
French Calf Boot Legs, per pair	4 00
Harness Leather, 30 lb	2 00
Fair Bridle Leather, 30 lb	45 00
Skirting Leather, 30 lb	34 00
Welt Leather, 30 lb	20 00
Buff Leather, 30 lb	19 00
Wax Side Leather, 30 lb	17 00
Eastern Wax Leather	20 00

SHAREHOLDERS, TRUSTEES, and SECRETARIES of ALL MINING COMPANIES.

Should see to it that their Notices are advertised legally in the MINING AND SCIENTIFIC PRESS, at much less cost than the usual rates of daily publications. Every person interested in the prosperity of legitimate mining enterprises should favor such practical economy. Send for circular of convenient dates for advertising, free blanks, and a copy of the New Code Corporation Assesment Law.

Continued from Page 309.

this tunnel up to the gravel beds is also finished. A portion of the timbers have arrived, and the erection of the hydraulic works has been commenced. Daily yield of ore, 60 tons. The erection of the foundation for the new machinery is making steady progress.

HALE AND NORCROSS.—Cross-cutting and prospecting on the 1,900-ft. level still goes steadily on without any important change or development. The cross-cuts on this level show the ledge to be immense, being now prospected over 180 ft. in width, and no indications of the east wall yet.

LEO.—The ore vein is not quite so wide as it was, but its excellent quality still continues. Its present width varies from a foot to fifteen inches.

KOSUTH.—The main north drift from the west tunnel at the first station level is in 240 ft. the entire size of the drift for the last 20 ft. being in ore of a fine quality. This drift has yet 60 ft. to run to reach the north line of the Dayton, and the body of ore opened is undoubtedly a continuation of that found on the second and third station levels of the Dayton mine. Cross-cuts have been run both east and west from this drift which have cut the ledge to the width of 80 ft. without reaching the east or west walls of the ledge.

CHOLLAS-POTOSI.—Daily yield 130 tons of ore, assaying \$32 per ton. The ore breasts and stopes are all yielding well. The repairs on the head of the hoisting engine are completed and work has been resumed at both the fourth and fifth station levels. The face of the main south drift at the fifth station shows considerable more quartz, and that of a much more lively and favorable character than has been encountered for some time.

NEW YORK CONSOLIDATED.—The water in the shaft is reduced to within 200 ft. of the bottom by the use of tanks. The new steam pump is almost completed, and will be in perfect working condition in a couple of days more. It is expected that the shaft will be drained ready to resume sinking by Monday next. As soon as the water is drained a station will be opened at the 550-ft. level, and drifts started to cut and prospect the ledge. Sinking the shaft will also be resumed as soon as the station is completed.

SAVAGE.—Cross-cutting the ledge on the 1,900-ft. level is still continued, without any new developments to report. The ledge on this level is wide, well defined and shows a large body of solid quartz, but no permanent body of ore as yet.

KNICKERBOCKER.—Sinking the shaft is going on at the rate of three feet per day. The seam of quartz before spoken of in our reports, still continues in the bottom of the shaft, and is of a very lively and favorable quality.

OVERMAN.—The main west drift on the 1,200-ft. level is still pushed vigorously forward, the face in vein material. No new ore developments to report.

IMPERIAL-EMPIRE.—Sinking the main incline is making steady progress. The main east drift on the 1,850 ft. level is still driven vigorously ahead.

LADY BRYAN.—New shaft down 130 ft. and sinking making good progress. The new hoisting works are fast approaching completion, and the erection of the new hoisting and pumping machinery is making rapid progress.

NEVADA.—Still continuing the main south drift ahead. The face of the drift is now in porphyry, the ore vein being left to the right. A cross-cut is started from the main tunnel, about 50 ft. south of cross-cut No. 1, which is now in 20 ft. in quartz all the way and no sign of west wall as yet.

WOODVILLE.—Sinking the incline is making steady headway. Both the up-raises from the north drift on the 300-ft. level are making the usual good headway.

SOUTH COMSTOCK.—Not sinking at present, but a cross-cut east is commenced at the 190-ft. level, in order to test the ledge at that point.

DANEY.—The main west drift, at the 400-ft. level, is in a distance of 30 ft. in good running ground. This drift will have about 250 ft. to run to reach the ledge.

LADY WASHINGTON.—The erection of the new machinery is making steady progress. Retimbering and repairing the shaft is almost completed.

ERIE.—The timbers having arrived for the shaft, work is actively resumed.

KENTUCK.—The east cross-cut on the 1,500-ft. level from the Crown Point is still pushed vigorously ahead, the face in quartz and porphyry mixed.

BULLION.—The north drift from the 1,700-ft. level of the Imperial is still making steady progress.

TYLER.—Putting in a new station at the 300-ft. level has occupied the entire week.

SOUTH STAR.—New shaft down 122 ft. Width of ledge in cross-cut at 100-ft. level not yet ascertained.

FLORA.—Water impedes operations considerably at winze No. 2. Ore assays range from \$10 to \$25 per ton.

ROCK ISLAND.—Sinking the new shaft is making steady headway. Now down 110 ft.

SUTRO.—Tunnel being driven ahead for the ledge, and making good progress.

SCIENTIFIC PRESS.—The attention of our readers is called to an interesting article on the Mining Interests of Northern Sierra, on the first page of this issue, from the SCIENTIFIC PRESS, San Francisco. This is the ablest, most instructive and influential Mining Journal published in the Great West, and should be liberally patronized by all our mining friends. *Mountain Messenger*, April 25.

A NEW BOOK.

SECOND EDITION—REVISED AND ENLARGED.

The Explorers', Miners' and Metallurgists' Companion.

Comprising a Practical Exposition of the Various Departments of Exploration, Mining, Engineering, Assaying, and Metallurgy.

Containing 672 Pages and 83 Engravings
BY J. S. PHILLIPS, M. E.

Of California, a Practical Operator for Thirty-four Years; Explorer, and Resident in the Pacific States and Territories for the past Eight Years.

PRICE, bound in cloth, \$10.50; in leather, \$12. Forwarded by mail for 50c. extra, by
DEWEY & CO.

Mining and Other Companies.

Owing to the time necessary to mail the present large edition of the *M. & S. Press*, we are obliged to go to press on Thursday evening—which is the very last hour we can receive advertisements.

Benjamin Mill and Mining Company.—Location of principal place of business, San Francisco, California. Location of works, Devil's Gate District, Lyon county, Nevada.

NOTICE.—There are delinquent upon the following described stock, on account of assessment (No. 1) levied on the 17th day of March, 1874, the several amounts set opposite the names of the respective shareholders as follows:

And in accordance with law, and an order of the Board of Directors, made on the 17th day of March, 1874, so many shares of each parcel of said stock as may be necessary, will be sold at public auction, at the office of said Company, Room No. 7, No. 401 California street, San Francisco, Cal., on Friday the 15th day of May, 1874, at the hour of 12 o'clock m., of said day, to pay said delinquent assessment thereon, together with costs of advertising and expenses of sale.

LEANDER LEAVITT, Secretary.
Office—Room No. 7, No. 401 California street, San Francisco, Cal.

POSTPONEMENT.—The above sale is postponed until Monday, the 18th day of May, 1874, at the hour of 12 o'clock m., at the office of said Company, Room No. 7, No. 401 California street, San Francisco, Cal. By order of the Board of Directors.

LEANDER LEAVITT, Secretary.
Office—Room No. 7, No. 401 California street, San Francisco, Cal.

Calaveras Gold Mining Company.—Location of principal place of business, San Francisco, State of California. Location of works, Washington Mining District, Calaveras county, State of California.

NOTICE.—There are delinquent upon the following described stock, on account of assessment (No. 5) levied on the 18th day of May, 1874, an assessment of fifty cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of the Company, in San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on the 16th day of June, 1874, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Wednesday, the 5th day of July, 1874, to pay the delinquent assessment together with costs of advertising and expenses of sale.

T. B. WINGARD, Secretary.
Office—No. 318 California street, San Francisco, Cal. (Room No. 13.)

Continental Silver Mining Company.—Location of principal place of business, San Francisco, State of California. Location of works, near Treasure City, White Pine County, Nevada.

NOTICE.—There are delinquent upon the following described stock, on account of assessment (No. 5) levied on the 4th day of May, 1874, an assessment (No. 5) of \$1.20 per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of the Company, 118 Front street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 16th day of June, 1874, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Tuesday, the 30th day of June, 1874, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

THEODORE BLANKENBURG, Secretary.
Office, 118 and 120 Front street, San Francisco, California.

Diamond Silver Mining Company.—Location of works, East Tintic Mining District, Just County, Utah Territory. Principal place of business, San Francisco.

NOTICE.—There are delinquent upon the following described stock, on account of assessment (No. 1) levied on the 10th day of April, 1874, an assessment of ten cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Treasurer, J. H. Fish, at the office of the Company, No. 123 Post street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 1st day of June, 1874, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Thursday, the 28th day of June, 1874, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

O. G. MILLER, Secretary.
Office—No. 123 Post street, San Francisco, Cal. ap28

CAST STEEL SHOE AND DIE COMPANY,

OFFICE—Room 28, Hayward's Building, 419 California St., S. F.

Patented CAST STEEL SHOES & DIES for Quartz Mills.

Price, 20 cents per Pound.

CAST STEEL DIE.

An improvement greatly needed—being Stronger, more Durable and Economical than Cast Iron: as the Dies, when worn down, can be welded to the Shoes as easily as bar steel, never break, keep their full striking surface. Battery of five shoes crushes one-ton more ore in 24 hours than Cast Iron Shoes, will wear as long as four set of Cast Iron Shoes, and can be worn down to 1/8 inch in thickness. The stubs can be welded into Picks, Hammers, etc.

ALSO—
Cast-Steel Tappets, Cams, Hammers, Gearing and Castings

OF ALL KINDS, A SPECIALTY.

It takes forty days to fill orders.

CAST STEEL SHOE.

All kinds of Cocks and Valves, Hydraulic Pipes and Nozzles, and Hose Couplings and Connections of all sizes and patterns, furnished with dispatch. PRICES MODERATE. J. H. WARD. V. KINGWILL.

Machinery.

N. Seibert's Eureka Lubricators.

THE HIGHEST PREMIUM

Awarded by the Mechanics' Institute Fair, San Francisco, and State Fair, Sacramento, 1871.

These Lubricators are acknowledged by all engineers to be superior to any they have ever used; feed constantly by pressure of condensed water, supplied by pipe A, regulated under the oil by valve J, and forced out through check valve and pipe B into the steam pipe C; it then becomes greasy steam, passes to all the valves and cylinder at every stroke of the engine; glass tube I indicates amount used per hour. Packing on rods and stems lasts longer, and the rings on the piston will not corrode. One pint of oil will last from three to six days, according to speed and size of engine; I, sliding gauge; K, valve to shut off when engine stops; H, F, valves to shut off in case of frost; steam does not enter the cup; it is always cool; warranted to give satisfaction. Patented February 14, 1871. Made by California Brass Works, 125 First street, S. F. 24v23-1f

STEEL SHOES AND DIES

FOR QUARTZ MILLS,

Made by our improved process after many years of patient research and experiment. We have succeeded in producing STEEL SHOES AND DIES for QUARTZ MILLS, which are unequalled for

THE
AMERICAN TURBINE WATER WHEEL.

Recently improved and submitted to thorough scientific tests by James Emerson, showing the following useful effect of the power of the water utilized, being
THE HIGHEST RESULTS EVER KNOWN.
Percentage of part gate, $\frac{1}{2}$ 50.03; $\frac{3}{4}$ 69.64; $\frac{5}{8}$ 78.73; $\frac{1}{4}$ 82.53; $\frac{3}{8}$ 82.90. Percentage of whole gate, 83.14.
Mr. Emerson says: "These are the best average results ever given by any Turbine Wheel in my experience."
A splendidly illustrated descriptive catalogue, or any further information desired, furnished on application to
TREADWELL & CO.,
SAN FRANCISCO, CAL.
Sole Agents for the Pacific States and Territories.
ap25-tf

TO HYDRAULIC MINERS.

I warn Hydraulic Miners not to be misled by the advertisement of Mr. F. H. Fisher. Said Fisher has been heated in every suit to which he has been a party (respecting Patent Rights on Hydraulic Machines), whether as plaintiff or defendant.
His patrons have already paid over Five Thousand Dollars for license to use machines purchased of the self styled
"Only Reliable Party in the Business
Who Protects His Customers."
Fisher's Machine is worthless unless the discharge pipe is furnished with appliances, the patent for which is owned by Messrs. CRAIG, and which Fisher is enjoined from making.
The Machine itself is also an infringement on another patent owned by the same parties.
All persons infringing on either of these patents
WILL BE PROMPTLY PROSECUTED.
I am sole LICENSEE to sell Machines manufactured under Craig's, Rice's, Macey's and Hoskin's patents.
I Guarantee Full Indemnity to all my Customers.
Machines of all sizes always on hand.
If you want a Machine that will give satisfaction, and do not want to pay for it twice over, buy an improved LITTLE GIANT.

Quartz Crushing & Ore Sampling
MILLS.
Nos. 413 & 415 Mission st., bet. First & Fremont, S. F.

Ours is the OLDEST, LARGEST and MOST EXTENSIVELY KNOWN establishment of this kind on the Coast.
Our mills are under the direct supervision of one of the most experienced Samplers and Millmen in the country, and we purpose carrying on the business upon a scale commensurate with the wants of the mining public.
We have the best facilities for Crushing, Sampling and Pulverizing all classes of Gold, Silver, Copper and Lead Ores and other minerals.
We also crush and pulverize all kinds of Marble, Fire-Clay, Bricks, Coke, Cement, etc., upon the shortest notice, for which we have special mills.
Reliable information furnished to miners and ore dealers concerning shipments, freights, prices, etc.
Prompt execution of all orders. Faithful attention to business entrusted to us.
Abundant storage room without extra charge.
ja31-tf "JIM" WHITLATCH, Sup't.

Varney's Patent Amalgamator.
These Machines Stand Unrivaled.
For rapidly pulverizing and amalgamating ores, they have no equal. No effort has been, or will be made to have them constructed in the most perfect manner and of the great number now in operation, not one has ever required repairs. The constant and increasing demand for them is sufficient evidence of their merits.
They are constructed so as to apply steam directly into the pulp, or with steam bottoms, as desired.
This Amalgamator Operates as Follows.
The pan being filled, the motion of the muller forces the pulp to the center, where it is drawn down through the aperture and between the grinding surfaces. Thence it is thrown to the periphery into the quicksilver. The curved plates again draw it to the center, where it passes down, and to the circumference as before. Thus it is constantly passing a regular flow between the grinding surfaces and into the quicksilver, until the ore is reduced to an impalpable powder, and the metal amalgamated.
Settlers made on the same principle excel all others. They bring the pulp so constantly and perfectly in contact with quicksilver, that the particles are rapidly and completely absorbed.
Mill-men are invited to examine these pans and settlers for themselves, at the office, 229 Fremont Street, San Francisco

Richardson & Co., Copper Ore Wharves,
SWANSEA.

Morris' Settler and Amalgamator.
PATENTED MARCH 25, 1873.
An important improvement in milling. Cheap, light, efficient and durable. Gains Quicksilver on working tailings. Is discharged from the surface in the center instead of the side, by means of a Syphon which extends to near the center of the Settler. Heaviest casting weighs only 135 pounds. The sides and bottom of the Settler are made of wood, as also Mullers, placed vertically—the friction of which quickens the quicksilver. One of these machines is in daily operation at No. 616 Merchant street, (basement), San Francisco. Parties desiring information as to rights of use, purchase, etc., can address,

The California Powder Works

No. 314 CALIFORNIA STREET,
SAN FRANCISCO.

Manufacture and have constantly on hand

SPORTING,

MINING,

And BLASTING

POWDER,

OF SUPERIOR QUALITY, FRESH FROM THE MILLS. It being constantly received and transported into the interior, is delivered to the consumer within a few days of the time of its manufacture, and is in every way superior to any other Powder in Market. We have been awarded successively

Three Gold Medals

By the MECHANICS' INSTITUTE and the STATE AGRICULTURAL SOCIETY for the superiority of our products over all others.

HERCULES POWDER.

We wish to call the attention of miners and others of our readers to a few points of superiority of the HERCULES POWDER over all other strong explosives.

FIRST—Its strength is greater than that of any other in use. The materials of which it consists are compounded upon strictly scientific principles, and not a simple neutral absorbent employed that will hold a quantity of nitro-glycerine. It is the opinion of the best chemists to whom the matter has been submitted, that no mixture has been employed that so thoroughly promotes the whole tremendous force of the explosives employed, and at the same time neutralizes the offensive gases caused by the explosion. With this Powder one half the time is saved that is lost by using any other strong powder, before you can resume work after a blast.

SECOND—UNIFORMITY.—The materials of the mixture are chemically prepared, and therefore greater uniformity can always be depended upon and the best results attained. This is a great advantage over any that varies in its strength, as those must which are mixed with any natural earth.

THIRD—SAFETY.—So perfect is this mixture that no accident can happen with it from premature or accidental explosion, if persons will half follow the rules laid down for its use. No powder has ever been invented where so few accidents have happened with it in proportion to the quantities which have been used.

FOURTH—CARTRIDGES.—It is well known that nitro-glycerine has a tendency to decompose by volatilization. These are the "fumes" that are smelted on going into a close warm drift or room where nitro-glycerine powders are stored. To prevent the escape of these "fumes" an almost hermetically sealed cartridge is employed, and so effectual is it that some cartridges filled with Hercules were exposed to a blazing California sun for six months last summer, with no perceptible loss of strength. This is a great advantage over the open porous paper usually used for cartridges.

FIFTH—ECONOMY.—We believe that any miner who will take the trouble to investigate the matter, will satisfy himself that full fifteen per cent. is saved by using the Hercules over any other strong powder manufactured.

QUERY—IS THIS WORTH SAVING? WE SHOULD TELL YOU. TRY IT. Sold by the CALIFORNIA POWDER WORKS, 314 California Street, San Francisco, Cal. Also, all grades of Black Powder, Fuse, Shot, Caps, etc.

BROWELL'S PATENT CHIMNEYS.

Fire and Earthquake Proof, can be placed in any part of the house with perfect safety. Light and strong, so substantially put up as to render them impossible to be shaken down by earthquakes; can be used as Heaters and Ventilators, and are unquestionably superior to anything of the kind invented in the United States. Are recommended by all architects and Fire Insurance Companies.

J. BROWELL,

449 Jackson St., N. E. Cor. of Montgomery.

GIANT POWDER.

Patented May 26, 1868.

THE ONLY SAFE BLASTING POWDER IN USE.

GIANT POWDER, NO. 1.

For hard and wet Rock, Iron, Copper, etc., and Submarine Blasting.

GIANT POWDER, NO. 2.

For medium and seamy Rock, Lime, Marble, Sulphur, Coal, Pipe Clay and Gravel Bank Blasting, Wood, etc.

Its EXCLUSIVE use saves from 30 to 60 per cent. in expenses, besides doing the work in half the time required for black powder.

It is the only Blasting Powder used in Europe and the Eastern States.

BANDMANN, NIELSEN & CO.,

General Agents, No. 210 Front Street.

THE ONE-PLUNGER JIG,

Delivered on R. R. Car at Denver, Col., or St. Louis, Mo.,

Separates in one and the same operation—1. galena and sulphide of silver; 2. pyrites or blende; 3. tailings, containing no valuable parts; or, 1. gold; 2. pyrites; 3. tailings (quartz, etc.) containing no valuable parts; or, 1. copper; 2. tailings, containing no valuable parts. The One Plunger Jig can be combined with existing stamp-mills with highly important advantages, as after amalgamation it will recover completely all fine metal and all base ores and all mercury out of tailings. It concentrates all fine metal ores to such cleanliness that low grade ores can be shipped, after concentration, as first-class ores. Its feed and discharge are automatic. Its construction offers better guarantee against loss and repairs than any other apparatus in use. For particulars, apply to the inventor, **F. CAZIN,** Mining and Civil Engineer, Denver City, Col. L. Box 2225. 13v28 1y

KABATH & LADD,

109 California Street, SAN FRANCISCO.

HAVE JUST RECEIVED IN PRIME ORDER, PER "OLEOPATRA" AND "SOLOMON,"

A FRESH SUPPLY OF

Cazin's Automatic Continuous One-Plunger Jig.

We illustrate this week, for the benefit of those of our readers interested in the subject of concentration of ores, Cazin's automatic continuous one-plunger jig. The principle applied in the machine is the same as applied in all successful ore separators of whatever description—the acting on the difference of specific gravity. The improvement embodied in this new machine is not based on any new principle. All features which had been proved as the most efficacious were maintained, and only the mechanical part was improved, simplified and rendered more effective, requiring less power by a construction closely adhering to true mechanical principles. The distinction of this machine from other contrivances lies only in the mechanical application of well recognized principles.

"A, in the drawing, Fig. 1, the perspective view, represents the trough or vessel on which the sieves for effecting the separation are arranged. The vessel is of suitable length, preferably with nearly semi-cylindrical bottom, and is stationary, secured on an supporting frame, B. At the ends the bottom is closed, except that the water-supply pipe, C, enters on one end, and that openings for the out-flow of water and waste rock are on the other end, at proper places. An inwardly opening valve shuts the end of the pipe. The upper part of the trough, A, contains a longitudinal partition, D, which, however, does not reach down to the bottom, serving merely to separate the plunger, E, on one side, from the sieves on the other. The plunger is a flat plate, pivoted at one end to the vessel, while its other end is, by a pitman, a, an oscillating crank and shaft connected with a slotted lever, b, in the slot of which the wristpin of a crank on the opposite shaft works. The plunger is thereby vibrated up and down. Whenever it moves up, the water is sucked in through the pipe, C, and drawn down through the sieves. Whenever it is coming down, it forces the water in the trough up through the sieves. The latter motion should be quicker than the former, for which object the wristpin of the crank is nearer the pivot of the lever, b, when swinging the same down, and further away from the pivot when swinging up. Transversely the trough has a partition between every pair of sieves, and also at the end of the last sieve. These partitions absolutely divide the trough into separate chambers for the collection of the several kinds or grades of ore, being only sufficiently recessed on top to permit the necessary vibrations of the plunger. The motion of the plunger being greatest near its connection with the shaft, c, a larger amount of water will be forced through the first sieve than through the next, etc.

Instead of there being only one sieve, there is a row of sieves. The sieves are not shaken in the water (jigged), but the sieves are steady, and the water is pushed through the sieves from below. The tailings are not scraped off, but a moderate

stream of water carries them off automatically. The action is not interrupted in order to scrape off first tailings, and then concentrated material, but the concentrated material passes through the sieves and valves continuously.

body is not square and apt to leak, but half-circular, drawn together by hoops. The machinery is not a special one for each sieve, but there is only one mechanical contrivance to move the water from under all the sieves, consisting in

Fig. 2 is a section through a b in Fig. 3; Fig. 3 is a section through c a in Fig. 5; Fig. 4 is a view of the discharge, showing the slide or gate, l, by which the quantity of water is regulated so as to keep all the sieves covered, and the escapes m1 m2 m3, corresponding to l and m in Fig. 7; Fig. 5 is a horizontal plan; Fig. 6 is a section through i k in Fig. 7; and Fig. 7 is a section through g h in Fig. 5.

The inventor, a mining engineer, claims that not only will this jig recover the entire percentage of useful material contained in the current of equal sized mineral rock and water fed unto it, and will do that work continually, automatically, without manual help, to an amount of one ton per hour, but also will, where quartz mills conduct their tailings, after amalgamation, into Cazin's jig, sieve, without any extra trouble, every particle of gold, silver, mercury, copper and lead, escaping after amalgamation, thus acting as a settler of superior quality. In some special cases it would be more advisable not to amalgamate under the mill, but first to concentrate by Cazin's jig, and to eventually roast and amalgamate subsequently. The apparatus will condense the metals and ores to such cleanness as to make them marketable and fit for shipment, as the best selected hand-pieces of clean metal or metallic ore would be, concentrating low grade ores of all kinds into first-class ores. By careful treatment the different metals and ores may not only be separated from waste rock, but be

separated, also, one from the other, as far as their specific weight differs, and the particles do not contain them in chemical or mechanical union. The inventor's address may be seen by referring to advertisement in another column.

GOLD COINAGE.—The director of the Mint, Mr. Lindermann, has addressed a letter to Senator. Sergeant, urging that the present charge for the coinage of gold should be abolished. Among the reasons are the following: First, the coinage charge reduces the Mint value of bullion, thereby encouraging its export to London and other foreign markets, where no charge is made for coinage. Second, the coinage of the standard metal being indispensible, the cost should fall equally upon all, and not upon the producers of the bullion. Third, a very small premium in London or Paris will cause gold bullion to be sent there merely for the on turn, whereas coin will not be exported, except when required to adjust foreign balances, and then only when it is the cheapest article obtainable for the purpose. Fourth, the repeal of the gold coinage charge would serve to retain the mixed bullion in this country for separation and coinage. Fifth, the small loss to the revenue which would result from a relinquishment of this charge would be made good by additional receipts from charges on molten refining, which have been imposed by the Coinage Act of 1873, which together with a gain on the subsidiary coinage now nearly defray the expenses of the entire Mint establishment.

A stock company, with a capital of \$50,000, is being organized in Colorado City, for the purpose of establishing a geological cabinet on a large scale. This is money well invested.

Fig. 5.

Fig. 6.

Fig. 7.

The supply of water is not alone from above, but also from below the sieves, carrying off the light particles of waste continuously. The

one plunger hung on a pivot at one end, moved on the other, thus doing away with some parts of construction, and much wear and tear.

ing organized in Colorado City, for the purpose of establishing a geological cabinet on a large scale. This is money well invested.

CORRESPONDENCE.

Mining in Plumas and Sierra Counties. No. 7.

(By our Special Correspondent.)

EDITORS PRESS:—In my last letter, for want of time, I was compelled to break off before finishing my article on the "Pioneer" at Grass Flat. Hoping you will pardon its unavoidably abrupt stoppage at the time, I will continue the same in this.

The Pioneer Company

Are still pushing their tunnel ahead toward the center of the dividing ridge, but for the last 100 feet they have been in bedrock. By a recent cave the fact was developed that fine wash gravel was but six feet above them; a fact that has been proven in all their former excavations. The company intend to run their tunnel until they reach the ground of

The Highland Mary Company.

By the peculiar location of Grass Flat ravine, which affords a fine outlet for hydraulic tailings many hundreds of feet above Slate creek, this company possess the rare advantage of a location that will enable them to run a sluice tunnel that will tap this well known rich channel at its greatest depth, and have a fall of over 150 feet below the present one. As this tunnel will only be about 1,000 feet in length to enable the company to commence piping, the day is not far distant when this mine will become as well known for its gold products as the celebrated Sierra Butte mine.

Immediately adjoining the Pioneer is the

Pacific Company,

Formerly known as the Manzanito company, who have spent about \$75,000 in sinking a shaft, and though a powerful steam engine was used, owing to the immense volume of water they encountered, the bedrock was never reached. The depth of this shaft is some 200 feet, all through fine wash gravel.

Adjoining the Pacific is the

Union Company,

Who have to work their mine under many disadvantages. The main tunnel is over 2,000 feet in length, through which the dirt is drawn by mule power, from eight to ten carloads at a time, after first being raised up a heavy incline of 190 feet in length, by water power, the bedrock pitching heavily toward the Pioneer mine in Grass flat. I see by the U. S. Commissioner's report to Congress, for 1873, as furnished him by the U. S. Deputy Mineral Surveyor, C. Hendel, Esq., of St. Louis, Sierra county, a gentleman of high standing in his profession, that in ten years the company have taken out \$463,344, paying a pro-rata of \$12.25 per cubic yard of gravel. Southwest of the Union, and adjoining, is the

Monte Cristo Company.

This like its neighbor, the Union, is also a tunnel or drift mine. The gravel is raised up a long, steep incline by a powerful steam engine. I also find, as per report mentioned above, that the company have realized in ten years the sum of \$543,649, which has yielded from every cubic yard of gravel excavated, \$6.47. The bedrock in this mine also pitches toward Grass flat. It is the opinion of all practical miners, that this mine, as well as the Union, will eventually be worked by the hydraulic process, through the projected Pioneer sluice tunnel, as mentioned above.

Many of your readers who are familiar with this section of the country, will recognize these mines as being situated at, what is termed, the "Slope." Why this embryotic town received the above name I have not learned, but suppose it was derived from its location on the western slope of the dividing ridge between Grass flat and Port Wine. Just below the "Slope," and adjoining, is the

Indian Queen Mine.

As to its present status, in mineralogical wealth, I am unable to say; but years ago it was considered one of the best paying drift mines in the northern section of the county. Further down this great channel is the

Eric Company,

Owned by Messrs. Lewis & Lerossier, of Port Wine. I am informed by Mr. Lewis that it is paying them well, and the gravel increases in richness as they advance toward the center of the hill. Near them are the Sallor, Golden Gate, Kinman & Co., and some French companies, some of which are being worked by hydraulic power. The central business place of this mining district is

Port Wine.

Rather an intoxicating name, I must confess, for so sober a looking town. Among the old familiar faces still remaining, who have shared alike its fortunes and misfortunes, I notice those of Amandus & Abraham Kleckner, of the well known firm of Kleckner & Bro., merchants, Harry Mason, post-master and merchant, Madame Cajan, of Cajan's hotel, Mrs. James Lewis, proprietress of the Golden Eagle hotel, Michael Wolff, of the Port Wine Brewery, and many others, all of whom have suffered more or less by the fire of 1871, which laid the town in ashes. In summer the town wears a cheerful aspect. But the Port Wine of years ago, as compared to the Port Wine of to-day, is, to the

reviewer, but a sorrowing remembrance of the past.

The deep snows of winter are furnishing an abundance of water to gladden the heart of the toiling miner. At

Laporte,

In Plumas county, a distance of three miles from here, Gowell & Conly, Gard & Orr, and the Spanish Flat company, have, by cutting through from 16 to 20 feet of snow, succeeded in getting their ditches open, and now have a copious supply of the much needed aqueous fluid.

An explanation is in place here, concerning an article that appeared in the SCIENTIFIC PRESS, of April 19th, unaccompanied by the *nom de plume* of the author, entitled "Mining in Sierra." The *Mountain Messenger* subsequently copying from the PRESS gives your correspondent, "Maximilian," the credit of writing the article, an honor I most respectfully decline, not that I doubt its truthfulness, but I do not desire to claim another man's thunder, no matter how heavy it rolls.

MAXIMILIAN.

Port Wine, May 13, 1874.

Undeveloped Resources.

EDITORS PRESS:—Mr. Bowman's interesting map of the mineral region of the State, accompanying his remarks in the PRESS of May 2d, gives rise to some other reflections, apposite to considering our undeveloped resources. The map depicts in black what may be called the "slate region," extending from Mariposa to Plumas counties, and again from Shasta to Siskiyou. Of course it would be an anomaly to suppose that good building slates abound in all that vast section of country, and yet up to this time they are not one of our industrial productions; and I believe we may look in vain in the directory of your metropolis for a single slate merchant. I am inclined to think, however, that the day is not far distant, when

Slate Quarrying

Will be a great industrial pursuit here; and I believe the sooner the better, that we may economize the wanton waste of our forests, by natural fire-proof substitute, for a great part of our buildings. It is indeed fearful to contemplate the annual waste of lumber all over the State, especially when so little planting is done to secure supplies for future generations, when necessarily the demand must be yet greater; and still more fearful would it be if some mighty conflagration destroyed the fair lineaments of your beautiful city. And there is not a city or town in the State, but what is liable to be burned out by the same unifying cause in a few hours, where frame buildings predominate. So far as we can do, it has already become the duty of the State to guard against such disaster and the more general use of slate, if procurable at moderate cost, is becoming a vital necessity. To encourage prospecting for slates, the general Government might do well to grant free homestead rights to every established quarry, and free rights of tramway through any Government lands, to connect with any trunk railroad or other road, canal or navigable waters, while this State might exempt from taxation, at least for two years, such quarries, machinery and tramway, and running gear, or give bounties for the discovery and actual working, with not less than 20 men, of slate quarries yielding some reasonable quantity of marketable slates annually. It is obvious that to bring

Slates into General Building Use,

They must be able to compete with shingle or other kinds of roofing in vogue. Perhaps, in the valley towns, the slate roofs should be white limed or cemented to keep out the heat, and they may also be used for the fronts or sides of houses instead of weatherboarding, especially in the localities where they are quarried. It would be quite possible, indeed, to erect a house almost wholly of slate and iron—iron forming the frame-work; of course the interior could be finished in lath and plaster, as at present. Allowing the necessity of its comparatively cheap production to compete with lumber, I think this may be accomplished after some years of successful working, even in our State, where labor and transit are expensive; but in the meanwhile, State bounty and exemption from taxation and homestead rights might be sufficient encouragement for capitalists to start the enterprise and bring it to a success; and eventually I think it could well take care of itself, and be as lucrative as it has proved in north Wales to many a lordly Baron. There is hardly anything more inviting to such capitalists whose wants bring with them a score or so of hardy Welshmen inured to the toil. They would find themselves at home in our mountain fastnesses and prove benefactors to the State.

Is the Idea Quixotical or Practical?

Farming was thought quixotical at one time in our State, and yet now for a long time it has taken the legitimate lead of all other pursuits, because it was a necessity; and a good substitute for lumber is only measurably less a necessity than farming, and superior in its beneficent object, to make our homesteads more secure and protect the interests of rising generations. I have already indicated that I think slate quarrying will eventually prove lucrative in this State, and, therefore, I must hold that slates are obtainable in abundant quantity—within the 250 miles or more of limit depicted on Mr. Bowman's map. It may be that the cropping generally are a kind of

Worthless Brittle Stone, Called Slate;

But no more like the far-famed Welsh Duchaes and Countesses than chalk is like cheese, or one of Shakespeare's heroes was like his ancestor. Still when the genealogy was traced back the progenitor could not be disputed; and, perhaps, by the same process of logical delving, we may diamter as fine black slabs from their peaceful beds in our State, as were ever converted into buffets or side-boards in the Principality to grace some royal or baronial banquet hall. There have been undoubtedly many failures in Welsh prospectings, but Penryhn had its beginning, and no one then augured the princely fortunes that have since been derived from that renowned quarry.

Ross Browne reports in 1868, "that the Amador slate is said to be quite equal to any found in Wales," and it would be interesting to know in this connection what success a company, organized in that county in 1865, have since met with. Browne also says, "although abundant on this coast but little of it thus far has been found good for roofing purposes." But the matter seems to be one deserving especial research, and as the geological features of the county must be much better understood at this date than they were almost ten years ago, the discovery may be much easier, while the incentive is far greater. I trust therefore, Messrs. Editors, you will do your utmost to encourage the enterprise, and if the communication should lead to the inquiry, I shall feel I have done something to aid the cause, be it ever so little.

It is, of course, well known that the usual tramroads from slate quarries may be very steep grades, and the loaded wagone attached to endless ropes or pulleys let themselves down and hoist, returning emptied, by their own momentum, without any team or horse-power, or even a man or boy to go with them, if I recollect right. Yours very respectfully,

A. F. G.

Sacramento, May 14, 1874.

The Missouri Quicksilver Mine.

A correspondent of the *Sonoma Democrat* writes as follows: The Missouri mine is in general in a good condition, and constantly improving. We have struck the ledge in our lower tunnel, and have splatterings of metal through the ledge, and expect before many days to make good a showing in our lower tunnel as in the one above, which enrely needs no spectacles to discern. Heretofore, our progress in tunneling has been greatly impeded by the want of timber, which it has been impossible to haul on account of the roads and the inclemency of the weather.

We have, under most trying circumstances, built a road of over a mile through the thickest of brush and boulder, up the little Sulphur creek to our wood land, and have a force of men cutting timber, and now have an ample supply, and our tunnels are undergoing repairs, of which heretofore they of necessity have been left in a dilapidated condition.

We are running three drifts and one winze, out of two of which we are taking metal. We have on the ground three new retorts, with apertures, and have a force of men clearing foundation for same. Macone will soon be at work, and we expect shortly to have silver running from these as freely as it now runs from our two small ones, the results of which have proven this mine the best in the district, and reflect great credit on the manager, Mr. W. A. Stuart, for his untiring efforts, energy and perseverance, to place the mine in its present healthy condition. The bright prospects of Cinnabar district and its notoriety throughout the State, are largely due to the efforts he has made in this instance. Property of every description is on the rise; the once barren and to all appearances worthless mountains are now dotted with tents and cabins, and signs of industry can be seen from every peak, showing conclusively that the reputation of the district is wide-spread. Localities that have heretofore hardly known the tread of man, are now gridironed with well-defined trails; over roads that had been scarcely traveled once a month, are now constantly rolling heavily laden wagons with lumber, provisions, etc. No less than ten wagons passed our door yesterday, bound for the Lost Ledge, etc., preparatory to the erecting of retorts; the managers of this mine are displaying great energy, and their prospect is such as to warrant their effort.

Mr. W. P. Litten, one of the most stirring men in the district, and Superintendent of the Peerless mine, on which he has several men at work prospecting the mine, paid us a flying visit, his countenance beaming with smiles, informing us that the mines in the vicinity of Pine Flat, such as the Georgia, Flagstaff and many others, were all looking well.

Mr. Charles Hossack, the Superintendent of the well known Geyser mine, called on us to have a friendly chat, and informed us of encouraging developments in that mine, which is already notorious for its richness.

The Rattlesnake is still exciting considerable interest with her rich deposit of free silver. Mr. DeNoon, the Superintendent, has 50 Chinamen engaged in building a road from the mine to Pine Flat, which will greatly facilitate the bringing in of their reduction works and provisions. After its completion, the force will continue the road to the Missouri mine, which will give an easy access to Pine Flat and be of great benefit to all the mines in this locality.

We have a force of men at work in the Kentucky mine, running a tunnel to strike the ledge 100 feet below the upper drift, in which we

have a large deposit of unexplored ore; also, men running a drift on the course of the ledge leading to the main body of ore; and from present prospect of the mine, we deem her second to none in the Cinnabar district.

I have great confidence in the richness of this district, and believe it will prove a source of wealth for those interested for years to come, and where we now see the comparatively insignificant retorts, we will yet see huge furnaces boiling the cinnabar and yielding the contents in the liquid form, far beyond the most sanguine expectations of the present owners, and that this district will yet prove adequate to fill the demand for quicksilver, which is failing from its once enormous source.

Why Many Mining Companies Fail.

The principal reasons why so many of the companies owning mines in Colorado and Utah have thus far proved such unprofitable investments, may be found in the facts: First, that in nearly every case, the prices paid for the properties have been, to say the least, double their value at the time of selling, thus incumbering the mines with an amount of capital, upon which it would be almost impossible to pay dividends. Second, parties purchasing were made to believe that only a nominal amount of working capital was necessary, and even this small amount, instead of being in cash, ready for use, was generally in stock, which of course was just about worthless if required to be sold. Third, large returns were promised and expected in a very short time, six months at the outside; conditions which very few mines in Colorado, with their present amount of development, can fulfill.

The owners, when they found that the dividends they expected were not forthcoming, and that they were required to put in cash in order to continue the operations at the mine, became disgusted and alarmed, refused to raise any more money, and declared the whole thing a swindle.

Any one at all conversant with mining knows that in the majority of cases, to carry it on successfully, requires a large amount of cash, and the great advantage which a company is supposed to possess over an individual, is its ability to furnish this cash, for the extensive working and development of its mining property, before getting returns. The poorest miner in our midst can work his lode advantageously as long as it will pay expenses and a profit, and when it ceases to do this, he can at least do as well as most Colorado companies have thus far done, that is, shut down the mine.

But we believe a new and brighter era is about to dawn upon the mining interests of our Territory. Parties desirous of investing in our mines in the future, should understand that in order to make the enterprise a paying one, great care should be exercised in the purchase of property, and after purchasing, a systematic and extensive method of prospecting must be inaugurated, backed of course by a liberal working capital. Under these conditions, mining, as a business can hardly fail to pay.

There are doubtless many good and promising lodes in the Territory which, if bought for a reasonable figure, and the requisite amount of working capital expended in development, would turn out equal to the best in the land. The lodes of Colorado, when compared with those of Nevada, show but a small amount of development. The mines of the Comstock have been opened and explored to great depths by means of shafts and drifts, showing in many instances a gradual increase in the quantity and quality of the ore. The same results will no doubt be obtained here by deep explorations.

In Nevada, mining operations are carried on principally by companies composed of wealthy San Francisco capitalists, who have made their money in mining, and know that in order to place a mining country on a paying basis, money in liberal amounts must be expended in opening up its veins. Where would the Belcher, Crown Point, Chollar-Potosi and the other famous mines of this region, be to-day if their owners had been afraid of investing money to develop them in times past? Last year the Belcher alone produced nearly seven millions of dollars and paid out over six millions in dividends.

Thus far, Colorado companies, both English and American, have been loth, apparently, to risk money in opening up their property after buying it, for fear, we suppose, that they might not strike pay. Consequently their operations have been limited. If, however, they would determine to give our mines a fair trial, we think that in a few years they would be well pleased with their investment, and prove Colorado to be one of the best mining countries in the world.—*Col. Mining Review.*

VOTING BY TELEGRAPH.—The members of the German Reichstag may hereafter do their voting by telegraph. The wires are to be arranged so that each member can indicate his vote from his seat. In front of the seat are two buttons—one indicating yes, the other no. A pressure on the button telegraphs the vote to a circular table in front of the President's desk, upon which the names of all the members are written down, so that immediately after pressing the button each member can see a piece of paper appear under his name, with his yes or no on it.

THOMAS HAYCOCK cleaned over \$1,700 from a nine days' run, with one pipe, in his claim, on Gopher hill, Plumas county.

MECHANICAL PROGRESS.

Paper Box Making Machines.

Among the most novel pieces of mechanical construction recently brought to public notice must be reckoned the machines invented by Mr. H. R. Heyl, of Philadelphia, for making paper boxes, and for the first time publicly exhibited at a recent monthly meeting of the Franklin Institute. The machines in question are the result of years of patient labor and perseverance, and the inventor is deserving of all praise for having so completely and efficiently triumphed over many difficulties. He has in the past seven years built three machines for making paper boxes, the last and most perfect of which has just been completed, and is the one referred to as having been placed on exhibition. As to the usefulness of machinery to produce paper boxes with greater rapidity and economy than by hand labor, little need be said, since a simple enumeration of the various branches of industry in which they are indispensable, affords superabundant evidence of their great utility—viz: perfumery, jewelry, hardware, trimmings, matches, and a host of other branches.

The first machine constructed by Mr. Heyl, for this purpose was adapted to the automatic shaping, and fastening by paste, of the usual rectangular box, varying the style according to the materials used. The capacity of this machine is 2,000 boxes in ten hours—a capacity which is equivalent to the duty of ten of the most expert workmen employed during the same time.

The second machine has for its object the production of boxes for various purposes without the use of paste, the fastening of the edges of the paper being accomplished by delicate pieces of iron wire, measured and shaped by the machine into miniature staples, which are pressed through the material and clinched at the proper instant. The primary design of this second machine was the production, at rapid rate and cheaply, of match-boxes and other cheap receptacles for tacks, screws, and various small articles; and the substitution of wire fastenings for the paste, besides greatly increasing the duty of the machine, is quite a desideratum on other accounts.

It is said by those familiar with the details of such trades, that the delay in drying the boxes when pasted, which often occurs in damp weather, frequently interferes with the shipment of large invoices of goods; in some cases of protracted damp weather, the paper boxes really mildew before they dry, and might ruin or seriously damage the goods packed in them. It was to obviate these obvious, but to others insuperable difficulties, that the inventor has produced the wire-fastening machine we have alluded to. The work accomplished by it is not only neater and stronger than that done by hand, but the rate of production of one machine is that of 75 workmen. The method of fastening the edges of the paper with wire staples is as follows: The wire is wound on a spool, from which the proper lengths are drawn by the machine for each box; the staples are formed and brought each to its place, at right angles with the box material, and are made at the proper moment to puncture it, upon which they are, an instant later, firmly clinched on the opposite surface. The power of impact exerted at right angles with an imposing surface, is here beautifully illustrated; and be it remembered that the entire production of the box is to be ascribed to the machine, every portion of the work being automatic. The machine seizes the elipe of wrapper singly, and shapes them, and throws out a match-box complete—even to being touched with glue and sprinkled with sand—at the rate of 30,000 pieces per day of 10 hours.

The third machine is simply a modified form of the one just described, in which its metallic fastenings and general movements are applied to the production of rectangular boxes of superior quality and of various sizes, applicable to safe packaging and display of articles of luxury, etc. The completion of these machines is a realization of the labor of seven years, and they are now busily plying their functions with perfect success.

The invention of the paper-box machine, by which the supply of articles indispensable to many of the small ware producers is vastly increased and cheapened, cannot fail speedily to result in the complete substitution of machine labor for the hand labor formerly universally employed for the purpose; while, from its perfect adaptation to the uses for which it is designed, and the mechanical ingenuity displayed in its conception and design, it is worthy of all praise.

PERPETUAL MOTION.—Some one asks the *Scientific American*: What, in your extended experience, is the nearest approach to perpetual motion ever accomplished by an inventor? Is there anything on record in the Patent Office, that is, has any person yet manufactured or arranged a machine, or invented any mechanical object, that would operate from a propelling power inherent in itself, without springs, steam or other motor known to mechanics, for a basis? If so, did it prove to be of any force or power, or did it promise anything useful? Please inform a reader of your paper and a well wisher to the American inventive faculty. The editor replies: The nearest approach to perpetual motion is the example of the man who

placed himself within a tub and, by a steady upward pull on the handles, expected to rise in the air. But he found that the tub was pushed down by his feet just as much as it was pulled up by his hands, or, in other words, that action and reaction are equal, and therefore failed to ascend. He has had many successors, who have aimed to overcome the difficulty by interposing levers or cogged wheels, arranged either to pull against each other, or placed between the hands of the operator and the handles of the tub. The principle is the same in all such cases, consequently the thing won't work. The simple tub is nearest approach to success because it is attended with less friction. The interposition of wheels or levers wastes a portion of the force. The jet of a fountain for example, will most nearly reach the level of its supply if allowed to rise in the air unobstructed. If the jet is compelled to turn a wheel or operate a lever, its height is of course diminished.

*The Marvels of Mechanics.

During the last siege of Paris, the inhabitants from time to time effected communication with their friends beyond the German investing lines by means of carrier pigeons. In fact, a regular pigeon post was organized, having one of its receiving stations in London. Here the written messages for Paris were received, and, by photography, reduced to microscopic size, each letter being reduced so small as to be invisible to the eye except as a speck. Some 2,000 of these specks were then printed on bits of tissue paper about an inch and a half square, which was rolled and carefully attached to one of the tail feathers of the pigeon. On the arrival of the bird in Paris, the postal officials placed the paper under the microscope, which enlarged the several specks into readable communications, which were duly copied in writing and delivered to the persons to whom they were addressed. The total postage received for the transmission of one of those tiny bits of paper frequently amounted to \$2,000.

Small as this photo writing seems, it has been surpassed by mechanism. In a recent number of the *Lens*, Dr. J. J. Woodward, U.S.A., gives an enlarged photograph of microscopic writing done by machinery on glass, by means of a diamond, executed by Mr. William Webb, of London. The writing consists of the Lord's Prayer, which is written upon glass, within a space equal to one two hundred and ninety fourth part of an inch in length by one four hundred and fortieth part of an inch in width, or a space perhaps equal to the dot in this letter i. The photograph given by Dr. Woodward shows this dot of writing enlarged so as to occupy a space of about two inches long by one and a half inches broad. All the words are brought legibly out on the photograph, the total number of letters being 227; and such is the exceeding fineness of the original writing that 29,431,455 letters written in the same way would only cover one square inch of glass surface. The combined Bible and New Testament contain in all 3,566,480 letters; hence it would be possible for Mr. Webb to write the entire contents of more than eight bibles within the space of one square inch. Two specimen plates containing the microscopic writing above alluded to have been supplied by Mr. Webb for the United States Museum at Washington. Their cost was \$50 each.

The Webb machine, however, does not equal in the fineness of its writing or perfection, the prior instrument of Mr. N. Peters, a wealthy banker of London, who, as long ago as 1855, was able to write nearly three times finer than Webb. So perfect was the Peters machine that it was competent to engrave the entire contents of the Bible and New Testament 22 times over within the space of a single square inch.—*Scientific American*.

THE STEAM SIREN OR FOG HORN.—Fog signals, many of which are required at different points on the Atlantic and Pacific coasts, are of several kinds. Some are steam whistles, the sound of which is made deeper or louder by being sent through a trumpet; but the most effective is probably the siren. This ingenious machine consists of a long trumpet and a steam boiler. The sound is produced by the rapid revolution past each other of two flat disks pierced with a great number of holes; a jet of steam under high pressure is projected against the disks, which revolve past each other more than a thousand times a minute; as the rows of small holes in the two disks come opposite each other, the steam vehemently rushes through, and makes the singular and piercing noise which a siren gives out. One of these machines costs about \$3,500 complete, with its trumpet, boiler, etc. Daboll's trumpet is worked by an Ericsson engine and requires no water for steam. Congress rightly has great confidence in the scientific skill and integrity of the Lighthouse Board. At the last session, besides the usual appropriation for the maintenance of the lighthouse system, it gave the money needed to build 40 new lighthouses and 10 steam fog signals. If we ever have a merchant marine of our own again, our seamen will find the stormy and rock-bound coasts of their country well lighted for them.—*Harper's Magazine*.

IMPROVED BLADE FOR AGRICULTURAL IMPLEMENTS.—The object of a new invention is to render hoes and other agricultural implements more durable, and it consists in making the outer corners of the blade thick and rigid, and making the blade thin, or bring it to an edge between the corners.

SCIENTIFIC PROGRESS.

The Astronomical Event of the Century.

Suppose a line drawn from the center of the earth to its surface at the equator; suppose another line starting from the extremity of this latter and continued till it terminates in the center of the sun, what is the mathematical expression which accurately describes the angle thus formed? Is it 8.92 sec., or is it .03 sec. more or less? That may appear a very abstruse and purely speculative question to some readers, yet all the science of navigation, and indeed, all the results of applied astronomy, have sprung from the approximate solution of this very problem. The slight amount of uncertainty, which still attaches to the answer, affects the accuracy of the lunar and planetary tables of every nautical almanac, and to a certain degree unsettles all questions of distance in regard to heavenly bodies, and of longitude in regard to places on the earth. The solar parallax is the scientific name of the angle whose character we have roughly indicated, and the slight uncertainty as to its true value renders it impossible to say within 300,000 miles just how far we are from the sun. When the total distance is equal to about 91,480,000 miles, to approach the certainty would seem to be near enough for all practical purposes. But forty times the earth's diameter is too extensive a departure from mathematical truth, even in regard to distances so enormous. Astronomers have, accordingly, set their minds on reducing this amount of uncertainty to a minimum of, say .01 sec., i. e., the absolute fixing of our distance from the sun, with a margin of 50,000 miles still open to doubt. Careful observations of the approaching transit of Venus are the means relied upon to accomplish this scientific feat.

Between the hours of 9 o'clock of our time on the evening of December 8 and 2 o'clock on the morning of December 9, of the present year, trained observers from nearly every civilized nation in the world will, from carefully selected points, be carefully scanning the passage of the planet Venus across the luminous disc of the sun. There has been no such phenomenon visible from the earth since 1769, and there will not be another, affording equal facilities for accurate observations, till the year 2004. Another transit will indeed take place eight years hence, but the sun's altitude above the horizon on that occasion will be too slight to present favorable conditions for observation. As the period of this year's transit occurs during the Northern winter, the base of observation must be established for the most part south of the equator. Points of observation must be marked off in pairs, because the entire problem depends on ascertaining with perfect exactitude the time at which various stages of the transit are observed at widely separated stations on the earth's surface. In fact, this method of fixing the angle of the solar parallax is simply a working out, on a colossal scale, of the familiar geometrical process of constructing two sides of a triangle in order to determine the third. The largest attainable base of the presumed triangle would of course be the earth's diameter—180 degrees. But suppose two observers situated this distance apart, and to the one the sun at the time of the transit would just be rising, while to the other it would be on the point of setting. For purposes of observation, however, the sun must not be lower, in either case, than 10° above the horizon. The easterly observer must be so placed that the egress of Venus from the sun's disc shall conclude not too near sunset, and the corresponding observer at the west must be able to watch the ingress of the planet a little after sunrise. Of course this cannot be accomplished without a contraction of base considerably within the limit of 180°.

The length of this supposed base of the triangle, whose apex is the sun, requires in the first place to be determined with mathematical accuracy. In other words, it is necessary to carefully establish, by lunar observation, what is called the absolute longitude of each station, and so to secure a perfect correspondence of astronomical time—say within a second—as a basis of observation between corresponding stations. This of itself requires some months of preparation, assisted by instruments of the utmost delicacy, and for the preliminary purpose several corps of observers are on the eve of departure from England to certain desolate regions of the Antarctic ocean selected as the one extremity of the terrestrial base for the required triangle. Of course the conditions of the problem are rather more complicated than can be briefly and popularly indicated. The relative velocities of the earth and Venus must be taken into account; their relative distance from the sun enters into the calculation, so do questions of atmospheric refraction, and other delicate points which can hardly be briefly indicated without the use of scientific nomenclature. But this much can be readily remembered: Venus, moving faster than the earth, crosses the sun's face from east to west. The most easterly of two observers, therefore, is the first to see the black orb of Venus completely within the outer rim of the sun's disc; in scientific phrase, he is situated at the point of "greatest acceleration." The companion observer at the westerly end of the line sees the same phenomenon some twenty minutes later, and is said to be at the point of "greatest retardation." Let the exact moment, say of two such critical points of the transit as the ingress and egress of the planet on the sun's disc be noted at each

station, and the absolute time interval between the observations of two stations be compared with the distance and qualified by the other conditions to which we have referred, and the much-sought-for angle will be nearer determination than it is to-day.

England, France, Germany, Russia and the United States are busily equipping astronomical expeditions to assist in solving what has been justly called "one of the sublimest problems of the universe." Telescopes, equatorially mounted, and driven by clock-work, so as to remain steadily fixed on the sun after being once pointed to it; photo-heliographs of the most delicate construction to present microscopically accurate transcripts of every phase of the transit; altazimuth and transit instruments, which are marvels both of massiveness and adjustment—such are among the articles required for the proper outfit of each expedition.—*N. Y. Times*.

GAIN IN WEIGHT BY COMBUSTION.—At a recent lecture before the Franklin Institute, Mr. Theodore D. Raud showed a simple and satisfactory experiment to demonstrate the increase in weight of burning bodies, caused by their absorption of oxygen. About an ounce of fine turnings of zinc, produced in the spinning of that metal, were loosely wrapped with iron wire and suspended from the arm of a balance. The pan on the other arm having been weighed to counterbalance the zinc, the latter was ignited with a match. At first the combustion was rapid, and much oxide escaped in fumes, causing the zinc end of the balance to rise. Soon, however, the combustion became a mere glow, the absorption of oxygen taking place without fumes. In a minute the beam began to descend and very soon decidedly outweighed the counterbalance. The only precaution necessary is to have the zinc moderately but not too compact. If too loose, it burns too rapidly; if too compact, it will not burn.

CONDENSATION IN STEAM CYLINDERS.—By the use of lead facings to pistons and cylinder lids, a considerable economy in the use of steam may be effected. An iron lid and piston will, other things being equal, condense more than three times as much steam as a lead-faced piston and lid. The thickness of metal heated and cooled at each stroke is not considerable, and not far into the metal a zone of constant temperature, lower than that of the steam, will be found. The distance from this zone to the inside of the cylinder will depend on the conducting power of the metal, and will be about 9 for lead to 12 for iron. It may be shown that, in any case, the thickness of the lead facing may be kept within very moderate limits. Other materials may be used for the same purpose, as, for instance, tin, the specific heat of which is 0.562, its specific weight being less than that of iron. Its conducting power is, however, in excess of that of iron, being as 15 is to 12. Slate or hard pottery ware might also be employed, but on the whole the balance of advantage appears to lie with lead.—*The Engineer*.

THE NECOMETER.—The Paris correspondent of the London *Standard* writes: There are people so mentally constituted that the idea that they may be possibly be buried alive preys upon their minds and makes them uncomfortable. Those among your readers who may be subject to this infirmity will be glad to hear that Dr. Bouchut, one of our leading practitioners here, has just got a prize from the Academy of Medicine for the discovery of a method to distinguish real from apparent death. In his excellent weekly bulletin in the *France*, Dr. Decaisins tells us what this discovery is. When the temperature falls to 20° above zero in the centigrade scale, (68° Fahrenheit,) death is certain. Dr. Bouchut has devised a thermometer, which he calls a necrometer, so graduated that when placed under the armpit of a person supposed to be dead it marks zero; then life has indeed departed beyond all possibility of a mistake. I mention this in the hope that it may catch the eye of some of our professional readers, that they may have an opportunity of expressing an opinion on the merits of the discovery of their French confrère.

TREATING ZINC ALLOYS.—A new invention relates to an improved method of recovering zinc which has been used for deilvering or separating other metals, chiefly lead. To carry this out the inventor arranges in a furnace one or more dry crucibles or melting pots, into which the alloy containing the zinc is placed. A tube passes from each of the crucibles, and connects it with a closed receiver, the mouth of the crucible and pipe connections with the crucible and receiver, as well as the crucible mouth, being luted or hermetically closed; the furnace is brought into action, and upon a white heat being obtained, the zinc volatilises and passes through the pipe into the receiver, where it is deposited in a metallic state.

FIRE ALARM.—An English inventor claims improved automatic means for indicating the presence of fire in buildings. These consist in hanging a strand of gun-cotton or other quick-burning substance about the building in such manner that on a fire breaking out it will be quickly ignited and explode one or more cartridges of gun-cotton or other explosive with a sufficiently loud report to give warning of the danger, or a bell or alarm may be likewise operated with the same object.

The blood of the insane is said to contain an excess of white corpuscles.

COLUSA COUNTY.

QUICKSILVER.—Sun, May 16: The reports from the quicksilver mines continue good. The Abbott is taking out a large quantity of very rich ore—so is the Buckeye. Mr. Gsither brought in some rich specimens of cinnabar this week discovered just west of his place, or some twelve miles north of Sulphur Springs. More prospects have been found further north on the Lovelace discovery. The mountains are full of prospectors.

LOS ANGELES COUNTY.

NEW MINING DISCOVERIES.—Herald, May 16: Mr. Bell, the discoverer of the new leads in the range of hills about seven miles northeast of our city, brings reports of additional discoveries which give indications more promising than the first. One specimen assays \$63.70 in silver and \$7 in gold to the ton. If the presence of gold and silver bearing ore, even in moderate richness, is demonstrated so near this city, with the attendant small expenses of working, the mines cannot but prove valuable. We await further developments with much interest.

MARIPOSA COUNTY.

WASHINGTON MINE.—Gazette, May 16: The prospects at the Washington mine are at present more favorable than ever before. The shaft has been sunk to the depth of 650 ft. At 600 ft. the vein is from 25 to 30 ft. in thickness and the rich paying strata not less than eight ft. thick. It is loaded with sulphurets of the richest quality, and the lowest estimate is that it will pay over \$25 a ton. The shaft is now at a greater depth than any mine in the county, and demonstrates that there has been, as yet, but little real quartz mining done in Mariposa.

MENDOCINO COUNTY.

QUICKSILVER.—Dispatch, May 16: The mining fever which has been raging so fearfully in Sonoma county is spreading into Mendocino. Several parties are out prospecting in different parts of the county. Mr. Loftus and George Cleveland have struck what they suppose to be a cinnabar mine a few miles northwest of Cayote valley. The claim of Cox, Hagan & Co., about four miles east of the Mountain House, which we have mentioned before, is likely to prove very valuable. Cox left town on Monday last with a lot of tools, windlass, ropes, etc., for further prosecuting of the work.

NEVADA COUNTY.

IDAHO MINE.—Union, May 16: We paid a visit to this justly famous mine yesterday, and found everything around the new shaft and the mill progressing as usual. But in addition to this they are now making ready to put a large pump in the old shaft. With this in view they are now engaged in repairing the landing and will, as soon as the machinery is placed in position, substantially retimber it, and then this will drain the mine perfectly. The machinery is being made ready, and next week the timbering will commence. The water is now being hoisted with the steam pumps that are located underground. The Burleigh drills have not yet arrived, but will be here shortly. It is estimated that when they are at work it will take twelve cords of wood, daily, to run the hoisting works and the condensers.

OMAHA MINES.—This enterprise has been idle for some time, and many thought that its abandonment had been determined upon. We are glad to know that Messrs. Sisson and Dndsworth, two of the stockholders, with full powers in the premises, are now in Grass Valley and that they have determined to resume work on the mine.

PLUMAS COUNTY.

GOOD RESULTS.—National, May 16: We are informed that Mr. Thos. Haycock cleaned up over \$1,700 from a nine days' run, with one pipe, in his claims on Gopher Hill. The big banks of splendid looking gravel indicate that he has many a long week's work ahead of him before he can call Gopher Hill worked out.

BANGER HILL.—The Plumas Ditch Co., Mr. Jo. Messerer, Supt., are getting the water running in their numerous claims, and from present indications will make a rich harvest this season. They have leased Mr. E. B. Jacks' claim, on Badger Hill, and have a couple of giants at work. We are informed that after eight days' run it was necessary to clean up a small portion of the main flume, below the branch flumes, and the clean-up amounted to the nice little sum of \$1,665. As it is reasonable to suppose that most of the heavy gold lodged in the ground-slices and branch flumes, the company have brilliant prospects before them. The water is certain to last from three to five months this year.

LONG VALLEY MINE.—Mr. Williams informs us that work commencing in earnest, and considerable prospecting will be done in the neighborhood of Little Long Valley, this summer. Sanderson, in McDermott ravine, has commenced piping, and has his claim well fitted up with iron pipe, a good flume, etc. Williams and partners are also fitting up, and will soon be in running order. Both claims prospect richly, and will give good results. The gravel in this ravine came from a break in the channel on which the Alturas claims are located, and its rich prospects speak well for the chances of the last named mine. Mr. Gould, the Supt. of the Alturas, informs us that work on the ditches will be commenced in a short time, and that the claim will be put in thorough running order this year.

HUONARIAN HILL.—On Monday, in company with Messrs. Goodwin and Kellogg, we paid a

flying visit to this splendid mine. The two giants on the "Quigley claim" were tearing down the gravel bank, and since the water season commenced, three times as much dirt has been moved on that side of the Hill as in all of last season's run. Supt. Goodwin has about twenty men at work, quite a number of them clearing out the ditches. As soon as the water is fairly running they will have four pipes at work steadily, night and day, and with the rich ground which they will work, an immense yield of gold is a certainty.

SAN DIEGO COUNTY.

JULIAN NOTES.—The mines have been inactive for a short time past, on account of too much rain, but are making ready for vigorous operations. The Golden Christ boiler has been en route since January, and twice mud-bound; arrived at its destination on the 9th inst., and it is to be put in place immediately, when the 10-stamp mill will be set to work. The old boiler is to be used for hoisting.

The 60-ft. level of the mine shows a ledge nearly 4 ft. wide, with magnificent rock prospects.

SAN LUIS OBISPO.

QUICKSILVER.—Tribune, May 16: There are ten flasks of quicksilver at the landing awaiting shipment. It came from the Mahoney mine, located sixteen miles north of Caycos. This is the first shipment from this mine. There are thirty other flasks belonging to this mine to be shipped next week. The mine is owned by Mr. Mahoney and other parties of San José. Good reports concerning its developments are heard at the landing.

SIERRA COUNTY.

WORK COMMENCED.—Mountain Messenger, May 16: Mr. Pickett, Supt. of the Rocky Point quartz ledge, has arrived from his home, in Sonoma county, and put a gang of men at work to finish the tunnel to tap his ledge. Work will be pushed, night and day, until the tunnel is completed. Before he left last fall, he erected a cabin and blacksmith shop, and put in a dam in the East Fork, a few hundred yards above the mine. He thinks 60 or 70 feet tunnel will tap the vein.

NEARLY READY.—Mr. Manson thinks he will have his quartz mill in operation by the first of the coming week. It will be put up at the foundry, and tested; and, if found satisfactory, will be taken to Code's quartz lodge, northwest of town, and put to work.

LA PORTE.—The mining ditches are about open for active operations, and the hydraulic works will soon be in full blast.

TRINITY COUNTY.

NICE GOLD.—Journal, May 16: We saw some specimens which came from the claim of Mead & Alden which were about as smoothly polished as the ore generally gets to be. The claim is on Mosquito Gulch, a tributary of Strophe creek. The largest of the lot weighed \$81, but the general size of the pieces was from \$5 to \$25. The gold is very heavy—one not used to it would be apt to estimate it far below its true value. Messrs. Mead & Allen have picked up about \$1,000 in this kind of gold this season without cleaning their ditches.

ENOUGH IN MINING.—Our "senior" is showing his faith in what the Journal has ever maintained, that is, the richness of the Trinity mines; by making preparations to open an extensive claim on Trinity river, just below the cañon.

TUOLUMNE COUNTY.

THE RIVERSIDE MINE.—Independent, May 16: The Riverside promises to turn out one of the best in the county. They have developed a splendid vein of $\frac{1}{2}$ ft., and are now running on a pay chute 60 ft in width along the vein, with no end as yet. Five or six carpenters are rushing up the mill, and the Superintendent evidently understands his business, which means that the property will not lack skill and energy to develop its merits.

We saw a beautiful lot of coarse, washed gold at the Express office, in Columbia, a few days since, which came out of a gulch near American Camp, a few miles northeast of the former place. One piece weighed eight ounces, without a speck of quartz or dirt to be seen in it. If the boys would only prospect the hill for gravel, they might strike some rich hydraulic diggings in that section.

Nevada.**WASHOE DISTRICT.**

SIERRA NEVADA.—Gold Hill News, May 14: Sinking the new shaft has been somewhat obstructed the past two days by a strong flow of water at the bottom. Sixteen car loads of the machinery for the new works have arrived, and the remainder is on the way from San Francisco. The total weight of the new machinery amounts to something over 220 tons, the principal spur-wheel alone weighing about 25,000 pounds. The stone foundation for this ponderous weight is about half finished, and when completed will contain 1,700 perch of stone. The foundation timbers for the machinery is all of the best red spruce, shipped from Dutch Flat, California, and is nearly all on the ground. The timbers and other lumber for the new hoisting works building are also fast arriving and will be framed ready for erection as fast as it is possible for the work to be accomplished. The sluices for the hydraulic works are nearly finished, and it is expected that everything will be in readiness to commence sluicing by the latter part of next week. Daily yield, 60 tons of ore, keeping the mill steadily running.

OPHIR.—The winze from cross-cut No. 1, 1,300-ft. level, has attained a depth of 50 ft., still continuing in fine ore; average assays, \$100

per ton. Cross-cut No. 1, 1,300-ft. level, during the week struck the east clay wall, which is well defined, with a strong dip to the east, proving the ledge at this point to be 450 ft. in width. Lying next to the east clay wall a stratum of very rich ore, 18 inches thick, was struck, which gives assays of from \$400 to \$600 to the ton. The south drift from this cross-cut has passed through 14 ft. of fine ore, average assays of which range from \$90 to \$100 per ton. The south drift on the 1,300-ft. level only lacks about 23 ft. of making the connection with the California north drift from the Virginia Consolidated.

BELCHER.—The main incline is down 17 ft. below the 1,500-ft. level, and blasting and cutting out for the purpose of opening the 1,500-ft. station has been commenced. The ore breasts throughout the entire mine are looking well and yielding splendidly. The ore breasts from the 1,000-ft. level upward continue to steadily improve. Daily yield, 550 tons of ore.

DAYTON.—Another drift has been started south in the ore vein from the main west tunnel on the second station level. The south drift on the second station level is in 120 ft., and is being pushed ahead to connect with the old Felix winze, sunk in 1864 or '65. This winze was sunk on a very rich chimney of ore, some of the ore working as high as \$82 per ton. It is expected that when this body of ore is reached a fine development will be made, as the drift will prospect the ore body at a much greater depth than it has yet been worked.

UTAH.—Sinking the shaft is making steady progress, the rock in the bottom working finely, and it is now down 25 ft. below the 400-ft. level.

CAWON POINT.—Daily yield, 550 tons of ore. The ore breasts on all the different levels, from the 1,400-ft. level up to the 1,000, are looking well and yielding the usual amount of rich ore. The ore breasts on the 1,400-ft. level are looking particularly well, and that level bids fair to outstrip, in point of yield, even the level above. The east ore vein, which was supposed not to extend above the 1,200-ft. level, is prospected nearly up to the 900-ft. level, at which point it is 12 ft. in width and of an excellent quality of ore.

GLOBE CONSOLIDATED.—Extracting ore from the upraise is still continued with an improvement, if anything, in the quality. A drift has been run 170 ft. below the winze, which has struck and is following the ledge to the northward, running through fine ore. The average assays of yesterday were over \$80 per ton. Provided this ore extends up to the ore body above, which it seems no doubt but it does, it will give a body of ore 330 ft. in depth.

SUTRO TUNNEL.—The main header is in 5,905 ft. to day, 37 ft. having been made during the week, with the additional assistance of one Burleigh drill, working in extremely hard rock. The drill carriage has arrived and additional drills are being put to work, consequently even better progress will be made in the future. At Shaft No. 2, the drift and pump stations and sump are completed, and all preparations being made, drifting both east and west, on the line of the tunnel, will be commenced to-morrow morning.

CALEDONIA.—The third compartment and repairing the shaft are about completed to the third station level. The main west drift at the fourth station level is being driven ahead at the rapid rate of 6 ft. per day.

CHOLLAR-POTOGI.—Daily yield, 120 tons of ore, assaying \$32 per ton. The ore breasts are all looking well and yielding finely.

GOULD & CURRY.—The quartz found in the bottom of the incline winze from the 1,700-ft. level has shown considerable improvement during the past week.

IMPERIAL EMPIRE.—Sinking the main incline is making good progress.

CONSOLIDATED VIRGINIA.—The ore breasts on all the different levels from the 1,000 to the 1,400 never looked more promising or yielded better than at the present time. The mills are all kept steadily running, and the future prospects of the mine grow brighter every day.

BALTIMORE CONSOLIDATED.—Sinking the shaft is making the usual progress, the flow of water from the bottom continuing steady and quite strong, though not enough yet to stop the sinking. The red spruce foundation timbers for the new machinery are all on the ground.

NEW YORK CONSOLIDATED.—The new pump is reducing the water in the shaft at a rapid rate. In a few days the shaft will be sufficiently dry to allow of sinking being resumed.

JULIA.—The ore developments in the east cross-cut from the main south drift on the 1,600-ft. level show a steady improvement, so much so that sinking the shaft for a new level has been commenced and is making rapid headway.

HALE & NORCROSS.—Sinking the main incline is making excellent progress, the rock in the bottom being quite soft and working out finely.

MINY.—Sinking the shaft is making steady progress. During the fore part of the week the flow of water seemed to decrease, but this morning was again increasing, although not sufficiently strong to greatly impede the progress of the work.

LEO.—The vein of rich ore in the face of the tunnel still continues, the width varying from six inches to two feet in width.

SILVER HILL.—The ore in the up-raise, from the south drift in the old St. Louis chimney, shows considerable improvement. The Sucker mill was started up yesterday on ore from this mine.

MCMEANS.—The main west tunnel is still driven vigorously ahead, the entire face in

quartz of a fine quality, and evident indications of the drift being just on the point of cutting the main ledge.

SUCCOR.—The Grant shaft is down 465 feet, the bottom in very hard blasting ground. The flow of water continues strong.

SOUTH COMSTOCK.—The cross-cut east, at the 190-ft. level, is to-day in 16 feet. The face is in hard blasting quartz, resembling the regular Comstock ore and assaying from \$8 to \$50 to the ton.

SAVAGE.—Opening the 2,000-ft. station, in the main incline, has been commenced, and is making good headway.

BULLION.—The north drift on the 1,700-ft. level of the Imperial is still pushed energetically ahead, following the body of black dyke lying next to the west wall of the ledge.

LADY BRYAN.—The erection of the new hoisting-works is making excellent headway.

KNICKERBOCKER.—Driving the main west drift on the 400-ft. level is making good headway.

UNION CONSOLIDATED.—Main north drift in 568 ft. from the Ophir shaft, following the west clay wall, and the face in a very favorable and promising formation.

CALIFORNIA.—The north drift on the 1,300-ft. level will probably make connection with the north drift from the Ophir during next week.

WOODVILLE.—The main incline is now down 65 ft. below the 300-foot level.

FLORIDA.—Water continues to impede operations in the winze, but good assays are obtained from the rock.

SENAIOR.—The west drift on the 400-ft. level is in 45 ft., the face in very favorable looking ground.

ELY DISTRICT.

RAYMOND & ELY.—Pioche Record, May 16: The cross-cut being driven for the vein from the 1,200-ft. station, has now attained a length of 185 ft. It is now in a formation which very clearly indicates that the drift is in the immediate vicinity of the ledge. The 30-stamp mill is crushing ore with 20 stamps, and part of its pans are working tailings on which mill No. 1 is entirely engaged. The yield for the five days last week was fair, being somewhat over \$15,000 for five days' run. One thing is very certain, that if either the Raymond & Ely or the Meadow Valley companies wish to sink their shafts, machinery must be obtained to free the mine from water, which may amount to no inconsiderable quantity.

MEADOW VALLEY.—No. 3 shaft—No effort was made during last week to resume the sinking on this shaft, as it is conceded that it, as well as the Raymond & Ely, has reached the water level of this region.

WASHINGTON & CREOLE.—Last week this mine sent something over a hundred tons of ore to be worked by the Floral mill. The returns so far promise to be very favorable, and the mill people are doing their best to secure a favorable yield.

PIOCHE.—Since our last, the work of sinking the new shaft for the present has been discontinued. The cross-cut that is being opened toward the ledge is 28½ ft. in length. Some considerable quantity of ore is being taken out of the old works by parties working on shares. By careful sorting, some very rich ore is obtained, which yields quite satisfactory returns when milled.

NEWARK.—A contract has been let to a responsible party to sink the old Amador shaft an additional 500 ft., and the work will be proceeded with without delay. Some five tons of ore are being raised per day and sent to the mill. The latter is being kept constantly busy on the company's and custom rock; and is doing good work. Superintendent Clute yesterday shipped half-ton to the amount of \$3,300.

AMERICAN FLAG.—Matters in this mine are in a very healthy condition. The shaft is being sunk as quickly as convenient. The lower levels are also being opened as rapidly as possible. The faces show fairly. In the upper levels stoping is being continued, and from the mine generally about twelve or thirteen tons of milling ore is being extracted daily. The mill is kept constantly at work on the company's rock, and the returns are quite satisfactory.

DESEMONA.—Has not been heard from for some time. A short time since two practical and industrious men, Messrs. Bull & Leavitt, leased this mine for six months, and have taken out some ore that has remunerated them very handsomely for their labor. They sent nine tons of selected ore to the Newark, formerly the Amador mill, and a return was made of \$700, which shows that our mines will yet richly remunerate the faithful laborer.

PORTLAND.—The returns from the last crushing were satisfactory, and generally the prospects of the mine are flattering.

CHIEF OF THE HILL.—The appearance of the drifts in this mine indicate some slight improvement. The streaks of pay ore are more frequent and of a better quality, and it is thought a more settled and valuable portion of the ledge is about being opened.

HAVANA.—The work of connecting the two shafts is almost completed, and when effected will thoroughly ventilate the mine.

A new mining district has been opened in San Diego county, near the base of Smith's Mountain, and distant from San Diego between forty-five and fifty miles in an air line, with good mining prospects.

They are talking about building a paper mill in Los Angeles.

Raymond and Ely Mills.

By the kind invitation of Captain Day, the well known and respected Superintendent of the Raymond & Ely company, we yesterday visited the company's mills. Leaving Pioche 9 A. M. behind a spanking team, which the Captain handled with the skill of a professional whip, we alighted at the office

In Bullionville

A few minutes after 10. So we made pretty good time going down. After a short stay at the office, where we found Mr. Eastland, the clerk, and Mr. Seavey, the Superintendent of the mills, who received us cordially, in company with the latter, who, by the bye, is an old Anstin man, who we have known for more than ten years, we started on a tour of inspection. We first looked into the 20-stamp mill, or

Mill No. 1.

The mill was not in motion, it having been stopped to put in two new pans. We learned that it had been running on tailings alone since July last, and is making very handsome returns. The arrangement of the stamps, pans and other machinery is excellent, and is well calculated to save labor and so promote economy. The propelling power is supplied by a powerful steam engine, of three feet stroke and 14 inch cylinder, which drives the 20 stamps, 12 pans, six settlers, an automatic feeder, crusher, pumps, etc., with great ease. Passing from thence to the 30-stamp, or

Mill No. 2.

We entered one of the most complete and well arranged quartz mills that it has ever been our fortune to observe. Commencing on the platform where the ore is delivered, we find a Blake crusher for reducing the ore to the proper size to place under the stamps. Then entering the battery room, we saw that the ore is fed by the means of a self-feeder, which constantly delivers the right quantity of ore at the right time. By this contrivance the stamps are enabled to crush the utmost they are capable of doing, for they strike close to the die with only a thin stratum of ore intervening, so that the force of the blow is utilized to the greatest possible extent. The crushed ore, now called "pulp," escapes from the battery through No. 40 wire screens, and is collected in tanks, from whence after the water is drained off, it is shoveled on the platform and distributed among the amalgamating pans. Of the latter there are 18 disposed on three sides of a parallelogram. The pans are charged with 2,000 pounds each, which is worked eight hours, when the contents are discharged into the settlers, where in a few hours the amalgam is collected, and the tailings allowed to run off. By a very ingenious but effective arrangement the quicksilver and amalgam are separated from the tailings almost automatically and fall into the strainers without any handling. After the amalgam is strained it is placed in an iron lined car, which runs on a track, and taken to the retort room, where it is shoveled into retorts, and speedily assumes the form of bullion, while the vaporized quicksilver passes off and is condensed in pipes immersed in cold water. It is impossible to give a description which will convey an adequate idea of the perfection of the various devices for handling the ore, pulp, quicksilver and amalgam. They must actually be seen to be appreciated. We thought we knew something about mills and milling, but we see that a long stride has been made in perfecting the arrangement and management of ore reducing machinery since we had anything to do with the business. We cannot, however, forbear from noticing the

New Quicksilver Pump

Invented and patented by Mr. Boss. Its simplicity is a marvel, but yet it is most effective. By its agency the quicksilver is distributed through pipes wherever wanted, thus saving a vast amount of labor and consequent expense, besides preventing any waste. Both the company's mills and the Magnet mill are fitted with this useful contrivance, and it gives perfect satisfaction. On leaving the mill, we found several hundred tons of ore collected on the dump, and is now in process of working. We also examined the large steam pump which supplies most of the water required for the works, and could not help commending the careful preparations made to subdue any fire that might break out. Coils of hose are ready for coupling, and as the large pump is always going, a fire would have but little chance to make much headway. We forgot to mention the splendid engine of the 30-stamp mill, which is a very fine piece of mechanism, plain, but solid and lasting. It is 42-inch stroke, 18-inch cylinder, with one of those whirling governors that makes one's eyes ache to look at. After leaving No. 2 we crossed the high trestlework to the

Railway Foundry

And found one of the most complete establishments of its size that probably can be found on this coast. Besides the casting apparatus, it is fitted with a splendid lathe, boring and screw-cutting machines, and planer. The foundry is a great convenience; in fact, is almost a necessity for the mills, for the pan bottoms, miller shoes and dies can easily be replaced with rapidity and economy. We found some quite large castings, for instance, a settler bottom, over six feet in diameter. After leaving the foundry we went to the

Magnet Mill,

Now under the efficient and careful management of A. Barber. We examined the ten-

stamp mill, and found it working on ore taken from the ground west of the Raymond & Ely proper. The appliances and machinery were pretty much of the same effectual and labor-saving character we have attempted to describe in the Raymond & Ely mills. We also visited Colonel Raymond's pet,

The Old Five-Stamp Mill,

Which first demonstrated the value of the ore deposits of Pioche. The battery, pans and engine are in excellent condition, and looked to us to be capable of performing as good work as ever. The mill was silent.—*Pioche Record.*

Gwin Mine.

The recent development in this mine surpassed anything which has ever occurred in its history, and we doubt much whether any greater strike has ever been made in any mine of gold on this coast if we consider the matter in all its bearings. The strike in the celebrated Morgan or Carson Hill mine was richer, but soon gave out, and so it has been with the rich pocket deposits in other mines. In the Gwin mine the case is different, for whilst the lead is not so rich as in many mines that we have seen, there is such a vast quantity of pay rock that the mine is now certain to be, from the time forth, a grand success.

We are glad to hear this news, which is fraught with good to our entire county. The face of the vein, 18 feet wide, in the 800-foot level, sheds a golden radiance upon the beholder, which carries conviction with it that "the clouds which lowered on this mine" are dispelled now and forever. We have been shown a letter from Judge Norman, who is now on a visit to the Gwin mine, written to a friend of his in San Andreas, from which, by permission, we extract the following facts: "It will be remembered that in the 600-foot level the pay chimney was about 350 feet in length and commenced 30 feet from the shaft—and the very next level, the 700-foot level, commencing in the shaft, was broken rock, and too poor to work until the pay chimney was struck again, at a distance of 210 feet from the shaft, and then the pay rock did not last but 125 feet, and that was the cause of the late want of confidence in the mine and embarrassment of the company. Another sinking was made, and the present tunnel started, with the following result: at 70 feet from the shaft a bunch of immensely rich rock was struck, but soon gave out, and, at intervals, splendid rock was struck, but nothing durable until the tunnel reached a distance of 250 feet from the shaft—it is argued, and we think with good reason, that these bunches of rich ore in the bottom of the tunnel commencing 70 feet from the shaft and continuing at intervals as already described, show conclusively that at the next sinking of 100 feet there will be a continuous lift of pay rock, far exceeding in length, width and thickness, that of the 600-foot level. At least, such is the opinion of Mr. Gleason, the present intelligent and energetic foreman of the mine.

"There are six men constantly at work on the face of this immense lead of eighteen feet in width in the 800-foot level, and the foreman says if it lasts for only 100 feet more (and there is no reason why it should not last as it did in the 600-foot level) that 60 stamps can not crush it in less time than one year. The mine has now reached a depth sufficient to be below the surface movements of the earth which have been caused by the convulsions of nature in days past, and as an evidence of it the rock in the mine is much harder and has a different tint, being now of a bluer cast than formerly, and the hanging wall, which has heretofore been soft and shelling, is now solid. Gold bearing sulphurets are disseminated all through this immense lode, and everything, gonge and all, is run through the mill. It pays at the rate of \$50 per day for each stamp, or over thirty dollars per ton. At present there are twenty-six stamps running day and night, and ten more are to be started immediately, while the twenty-four stamp mill, which was erected to work ore from the Alexander mine, is in fine condition and will commence crushing from this lead as soon as additional stopes can be opened and ore obtained. There is another very important fact connected with this mine. The Alexander mine, which now forms a part of the Gwin mine, struck barren rock at a depth of 300 feet, as did the Gwin mine also. The Alexander mine was worked to no greater depth than 300 feet, and the Gwin company are sinking their shaft at the 800-foot level, on the vein, to see if they can find the pay chimney of the Alexander mine. The foreman says they have run through rim matter, gonge and broken rock, with good walls for nearly 200 feet, and is confident that inside of ten days he will develop a pay chimney in that direction; he says water has made its appearance in small quantities there, which is a good sign, and there is every possible indication of the lead being struck soon. If that chimney should be struck in connection with the recent developments in the south part of the mine, it will be hard to estimate in dollars the real value of the Gwin mining property. The Hayward mine of Amador in its palmy days never paid better than the Gwin mine is paying now, nor ever had a brighter prospect ahead."—*Calaveras Chronicle.*

KALSUMINE wash may be applied to any wall. If common whitewash has been used previously it may need to be scraped off before the kalsomine is put on. A kalsomined wall can not be washed like one in hard finish; washing will remove the coat.

Tybo District.

The indomitable McGee and his "2 G" venture have both of them met with the most unqualified success in the modern Babel. The promptitude with which \$300,000 were subscribed for a working capital will attest these facts. A small private joint stock company has been formed, the members of which, as soon as the necessary papers, such as abstracts of titles, maps, reports, etc., were laid before them, without further delay, paid into a common fund sums which amounted to the aggregate as above written. There are neither stock nor corporate papers issued yet, nor will there be either, for several months to come, or till the mine will have been proved to be in every respect worthy of public confidence; then, and not till then, will it become a corporate concern. This is a move in the right direction, and one, too, that will ultimately redound to the interests of its owners and vendors. Their present province will be to erect suitable buildings, such as boarding and lodging houses for the employees, offices, furnaces, water-tanks, ditches, etc. They will, and have already proceeded to open up the mines in such a manner as cannot fail to early demonstrate their value and permanency.

Nothing will be left to chance, for they intend to prove by their brilliant product that their worthiness will be founded on something more real and tangible than the mere exhibits, which are usually put forth upon paper by those having mines to dispose of in London or elsewhere. The day has, however, already passed when unprincipled schemers can successfully float an undeveloped mine in that metropolis. The Parks and the Harpendings of the Pacific coast have had their day. The Emma, Mineral Hill, Eberhardt, Aurora and Pacific, and Maryland of Pinto fiascos, have forever put a quietus upon the chance of anybody ever again making a large haul out of such worthless concerns, and it has been long since proved that they were even at the very outset of their careers in quest of purchasers. The "2 G," very happily for its owners, can bear the closest scrutiny, consistent with honor and fair dealing. Its merits are well known, and they, together with the high reputation borne by the gentleman who purchased it last January, have been all the guarantees that were required by those who very readily placed the princely sum mentioned at the disposal of its Superintendent, with which to inaugurate operations in that district preparatory to commencing business in real earnest next July.

There are 20 men already employed there, grading, building and extracting ore, the whole under the direction of Mr. Packard, 1st of the Richmond, who has entire charge in Mr. McGee's absence. It is in contemplation to have one furnace in running order by the 10th of July next. Everything that ample means and unfagging energy can accomplish is being done at present. Mr. McGee, with an eye to business, has recently bought of the owners the Freiburg furnace, tweezers, and machinery, such as engine and boiler, blowers, slag pots, trucks, bullion molds, ladders, blacksmith outfit, etc., all of which are to be immediately transported from there, a distance of sixty miles, to the works at Tybo. The furnace is chiefly valuable for the Pensacola fire stone used in its construction. By and by other furnaces—both smelting and refining—will be erected, on a scale commensurate with the character of the enterprise. Suitable separating works are also to be built, at the proper time.

This latter undertaking will, when completed, entirely do away with the onerous charges which the freight upon crude bullion would entail from the mine to distant refineries. Goods have been already shipped from here to there last week, by a magnificent ten-mule team and three wagons, recently purchased for the company by Mr. McGee, at an outlay of \$3,500. These goods consisted of boarding-house furniture, mining tools, nails, powder and fuse, and such other things as are known to be necessary appendages of a new camp. The future of Tybo promises to be a bright and prosperous one; and Enreka, from its position along the line by which supplies are to be received, cannot fail to derive much benefit from the trade which will henceforth flow to its merchants from it.—*Eureka Sentinel.*

COLUSA QUICKSILVER MINES.—From all we can learn we are satisfied that the country around Sulphur Springs is the richest in cinnabar of any district in the United States. Mr. Bartlett, an experienced miner, in a letter to us this week says: "There is great excitement here on account of recent discoveries made by Lovelace and Noble on the west of Bear valley. They have found the richest prospects I ever saw. The ore will go from twenty to thirty per cent., and they say it came from the croppings. Mr. Caswell, of the Buckeye, was called upon to examine their discovery, and he reports very favorably. He had some four or five pounds of the ore that would assay some forty or fifty per cent. I start out soon on a prospecting tour. The Buckeye is the best mine in this part of the country. They are reducing about two hundred pounds of quicksilver daily. The Abbott mine is good, and I think the present company will make a good thing of it. The Chapin mine is also good. They intend putting up a furnace at this mine. They have enough ore in sight to pay for the work." As will be seen by a notice in another column, the Abbott calls a meeting of stockholders for next Tuesday. Cinnabar is being taken out of two tunnels in this mine, and they have out now about two hundred tons, estimated to yield ten

to fifteen per cent. on the average. It is the intention of the company to put up a furnace in a short time. When the three furnaces now contemplated shall be in operation, we shall ship several thousand pounds of quicksilver daily from Colusa. And if the new discoveries prove as rich as indications warrant us in believing they will, several other furnaces will be put up during the summer.—*Colusa Sun.*

Agricultural and Mineral Lands.

A correspondent of the *Alla* writing from Calaveras county says: Calaveras at one time was the banner county in the State, politically and mineralogically. She has lost considerable of her former greatness, but at this time seems to be looming up, and if her mining interests are not injured by legislation, we believe that she will soon again rank high, not only as a mining county, but as an agricultural section. Agriculture and mining should walk hand in hand together here, as neither is strong enough to sustain our present population alone. These interests should be harmonized. There should not be any conflict between the two; but a conflict seems to be inevitable. Some of the best mining land is being "proved up" for agriculture.

The man who has "proved up" for agriculture, claims that the miner has no longer the right to prospect for either placer or quartz on his land, while the miner seems to think that an "agricultural patent" does not exclude him from mining. The requiring of the party opposing the patent to go to Sacramento has, without doubt, acted against the miner. It is expensive, and oftentimes the miner is not posted sufficiently in regard to the locality of the sections referred to, in the survey, in the published notices, to enable him to tell where the land is located. So it passes along till he is informed, he is trespassing on *my land*. He is required to stop work, and soon the little he has saved, if any at all, is used up in keeping his family from starvation by paying for all they consume, the San Francisco prices, with the freight added, which is generally one cent per pound from that city to the mineral belt.

There should be something done soon to reconcile these interests. If our members of Congress cannot intelligently manage this matter, let there be a Joint Commission appointed by the State Legislature and Congress to examine into all the bearings of this question that threatens to cause so much difficulty in this section. We believe that agriculture will eventually claim most of this region, although deep gravel diggings and quartz mining is yet in the cradle of its greatness.

Newfoundland District.

A correspondent of the *Salt Lake Tribune* writes as follows about the district: Newfoundland District is situated south of Terrace and some fifteen miles from the C. P. R., on an air line; but by way of the usual traveled wagon road, it is nearly twenty miles. It is known on the map of Utah as Desert mountain, and in length it is some eighteen or twenty miles. Its average breadth is four miles. There are some twenty springs of good palatable drinking water on the east and west sides of the mountain, that flow continually the year round. Wood is plenty for domestic purposes, but not of sufficient quantity to supply mills or furnaces for a great length of time.

In the lower hills which surround the mountain, there is an ample supply of grass to furnish 2,000 head of stock during the entire year.

The Mines.

The principal mines are situated on the southwest side of the highest peak of the mountains, in what is known as the Quartzite belt, which, in width, is from one-half to three-quarters of a mile. The mines run parallel to each other, and crop out in places ten to fifteen feet in height. Yet the croppings stand out boldly along the entire length of the chains. The width of the different ledges varies from ten to fifteen feet. Those situated at the lower edge of the Quartzite belt contain a considerable amount of copper that assays from fifteen to fifty per cent., and also contain gold and silver, of the former from five dollars to twelve dollars per ton; while of silver, choice pieces assay above \$100 per ton. The assays have been more favorable as depth is reached. The lowest depth yet sunk on any one claim is some eighteen feet, which work is done on the Oregonian mine. From this the best assays have been made. These are thought to be continuous or true fissure veins.

The proximity to the railroad, the character and abundance of ore, as well as the almost natural road from the mines to the railroad, make this a desirable district for capitalists to invest their money with a surety of speedy return.

The owners of the Providence mine are putting in works for the reduction of sulphurets by the chlorine process, at their mill on Deer creek, Nevada county. The works will have a capacity of reducing two and a half tons of sulphurets per day, and with the present force at work in the mine that amount of sulphurets can be furnished.

Rich and extensive placer mines were discovered in the bed of the Jefferson river, about fifty miles from Bozeman, running parallel with what is known as the Davis Bar, on the 8th of April. Three men, with a small wing dam and rocker, obtained \$375 in six days' work from a small patch of ground. Bed-rock was reached at three feet.

USEFUL INFORMATION.

Black Varnish for Zinc.

Professor Böttger prepares a black coating for zinc by dissolving 2 parts nitrate of copper and 3 parts crystallized chloride of copper in 64 parts of water, and adding 8 parts of nitric acid of specific gravity. This, however, is quite expensive; and in some places, the copper salts are difficult to obtain. On this account Pucher prepares black paint or varnish with the following simple ingredients: Equal parts of chlorate of potash and blue vitriol are dissolved in 36 times as much warm water, and the solution left to cool. If the sulphate of copper used contains iron, it is precipitated as a hydrated oxide and can be removed by decantation or filtration. The zinc castings are then immersed for a few seconds in the solution until quite black, rinsed off with water, and dried. Even before it is dry, the black coating adheres to the object so that it may be wiped dry with a cloth. A more economical method, since a much smaller quantity of the salt solution is required, is to apply it repeatedly with a sponge. If copper colored spots appear during the operation, the solution is applied to them a second time, and after a while they turn black. As soon as the object becomes equally black all over, it is washed with water and dried. On rubbing, the coating acquires a glittering appearance like indigo, which disappears on applying a few drops of linseed oil varnish or "wax milk," and the zinc then has a deep black color and gloss. The wax milk just mentioned is prepared by boiling 1 part of yellow soap and 3 parts Japanese wax in 21 parts of water, until the soap dissolves. When cold, it has the consistency of salve, and will keep in closed vessels as long as desired. It can be used for polishing carved wood work and for waxing ballroom floors, as it is cheaper than the solution of wax in turpentine, and does not stick or smell so disagreeable as the latter. A permanent black ink for zinc labels is prepared by dissolving equal parts of chlorate of potash and sulphate of copper in 18 parts of water, and adding some gum arabic solution. The black polish above described is recommended as permanent and capable of resisting quite a high temperature.

How to Varnish.

Varnish should always be applied in a warm room, as warm as a person can work in comfortably. At a lower temperature there is always moisture in the air, an invisible dew, which gives the varnish a milky and cloudy appearance. This will happen even on a fine summer's day, and the only preventive is to employ artificial heat to produce a temperature of at least 75° F. At this temperature the moisture is not precipitated until the alcohol of the varnish has sufficiently evaporated to leave a thin and smooth film or shellac. The gloss and durability are entirely dependent upon this. The article to be varnished should be brought into the workshop a few hours before the work begins, so that it may get warm. The surface is smoothed, washed and rubbed dry with camellia leather, or a piece of silk, and every trace of dust, moisture and dirt removed with a clean, soft brush, but no oil or grease must be used. The varnish is now lifted lightly with a flat brush not immersed too deeply in it, and a thin coating applied. It is well to begin in the center or at the highest part, and approach the edges with long, straight, rapid and even strokes, and a gentle pressure. Care must be taken at the corners and edges. The film of varnish should be about as thick as a sheet of paper. When finished it should be exposed to the sun's rays or artificial heat, and carefully protected against draft and dust. Cold air or a draft over the article gives the varnish a dull look. When this happens the only remedy is to apply a second coating, and hold it near the fire so as to dissolve the previous coat, but not so near as to blister it.—*Jour. of Ap. Chem.*

TO CLEAN PAINT.—There is a very simple method to clean paint that has become dirty, and if our housewife should adopt it, it would save them a great deal of trouble. Provide a plate with some of the best whiting to be had, and have some clean warm water and a piece of flannel, which dip into the water and squeeze nearly dry; then take as much whiting as will adhere to it, apply it to the painted surface, when a little rubbing will instantly remove any dirt or grease. After which wash the part well with clean water, rubbing it dry with a soft camellia. Paint thus cleaned looks as well as when first laid on, without any injury to the most delicate colors. It is far better than using soap, and does not require more than half the time and labor.—*Coachmakers' Journal.*

GLYCERIN FOR PRESERVING FRUIT.—We learn through a German journal that in order to preserve fresh fruit it is only necessary to heat them, if not perfectly ripe, in water almost to boiling, drain nearly dry, and cover with warm concentrated glycerin. If the fruit is perfectly ripe, heating in water is unnecessary. It is also advised to pour off the glycerin after standing for some time and add fresh concentrated glycerin. The glycerin poured off may be concentrated on a water bath and used a second time. Ordinary glycerin is often impure, but only that which is perfectly pure and colorless, with a clean, sweet taste and a specific gravity of 1.25, should be employed.

INCOMBUSTIBLE FINISH FOR WOVEN FABRICS.—The *Manufacturers' Review* translates from Hager the following directions for preparing a starch paste, impregnation with which renders a fabric incombustible: 10 parts of calcined and pulverized bones are treated with 50 parts of hot water, to which six parts concentrated sulphuric acid are gradually added. The mixture is well stirred, and left to stand two days in a warm spot, being stirred from time to time; 100 parts of distilled water are then added, and the liquid filtered. Five parts sulphate of magesia (Epsom salts) are dissolved in 15 parts of distilled water, the solution added to the first, and caustic ammonia added till the liquid smells of it. The precipitate is thrown on a linen filter, pressed, dried in a moderately warm place, and rubbed to a very fine powder. Of this powder, two parts are mixed with exactly one part of tungstate of soda, and six parts wheat starch, and a little indigo blue added to impart a bluish tint to the powder. In order to use this powder, it is stirred up with about twice its weight of cold water, and enough hot water is then added to produce a gelatinous liquid, in which the fabrics that are to be rendered incombustible are steeped.

TO INVENTORS.—An authority lays down the following maxims for the guidance of inventors:

1. Know definitely what you want to accomplish, stick to it, and let other matters go, for the time.
2. Post yourself thoroughly as to the laws governing the action of each part of your machine.
3. Always bear in mind that whatever is gained in time is lost in power, and vice versa.
4. Think over every machine, of a nature similar to yours, which you have seen; and when your idea is clear in your head, compare it with those of inventors who have preceded you in the same line.
5. Be sure that the cost of your device will not prevent its use.
6. Avoid all complicated arrangements; make every machine of as few parts as possible.
7. Imagination, judgment and memory are the faculties to employ. Imagination will bring forth new forms and actions, judgment will compare them with other devices and determine their relative value, and memory will store up the results for future use.

SAWDUST is sometimes prepared for moulding and for stopping cracks or holes to disguise flaws or other defects in woodwork. In order to prepare the material, the sawdust is put in an earthen vessel, boiling water poured on it, stirred up, and left to soak for about a week, and again stirring from time to time; then it is boiled until it has attained the consistency of a paste, after which it is put in a coarse cloth and the excess of moisture well squeezed out. This material is then kept ready for use; when wanted a sufficient quantity of thin glue-water is added so as to obtain a paste, which may be pressed into moulds, or rubbed into cracks or holes to disguise flaws or other defects in woodwork. When the sawdust of the same wood is used, the work carefully done, well dried and cleaned, the imperfections repaired in this way can scarcely be detected; while the ornaments made differ only in one respect from those made by carving—in not showing the grain of the wood.—*Builder.*

TO RENDER GLASS OPAQUE OR FROSTED, according to *Dingler's Journal*, a sheet of ordinary glass, whether patent plate or crown does not matter, is cleaned; and if only portions of it are to be frosted, those are left bare, while the others are protected by mechanical means in any simple manner. Some flour spar is rubbed to a fine powder and mixed with concentrated sulphuric acid, so as to make a thin paste, and this is then rubbed, by means of a piece of lead, upon those parts of the glass required to be rendered opaque. A fine frosted outline or design may thus be produced upon a sheet of smooth transparent glass. To finish the operation, the glass is gently heated in an iron vessel covered with a funnel passing up the chimney, to get rid of the noxious fumes that are given off; on cooling, the plate is washed with a dilute solution of soda or potash, to remove any acid yet remaining, and is then rinsed in water.

To case-harden 1-32 of an inch, so that a file will not cut it, take prussiate of potash three pounds, carbonate of ammonia one pound; pulverize and spread over the surface to be hardened, with a metal or wooden spoon, in the same manner as in the old method of potash hardening; put the article so treated into a spring furnace oven or on a blacksmith's fire, and keep at a cherry red heat for fifteen minutes; then plunge it into a cold bath composed of two barrels of rain water, ten pounds of eel ammonia, ten pounds of alum and five pounds of borax.—*Car Builder.*

TO MEND CHINA.—We have tried a dozen different recipes and cements for mending broken china, and have come to the conclusion that the best way is to buy new. A china preservative dish that has been mended is a ticklish thing to handle, especially if full of sweetmeats, and when one hes on her "company clothes."—*N. Y. Tribune.*

TO REMOVE THE IRON TASTE FROM NEW KETTLES.—Boil a handful of hay in them, and repeat the process if necessary. Hay water is a great sweetener of tin, wooden and iron ware. In Irish dairies everything used for milk is scalded with hay water.

GOOD HEALTH.

"Spring Biliousness."

There are few of our rural readers who will not readily comprehend the meaning of the above caption. Of course, the term "biliousness," like charity, is made to hide a multitude of sins; but in this article we simply mean by it that condition of general lassitude so universally observed with the coming of spring. And very often something more than lassitude is experienced; for malarial fever in its various types, together with an occasional case of typhoid, make their appearance wherever climatic or physical conditions afford them the slightest foothold. To obtain a fair insight into any symptom or set of symptoms which constitute a disease, it is necessary to understand something of their causes, and so we will look for a moment into those causes which would seem to favor or induce these "spring fevers." One of the first, no doubt, is the marked difference in diet and physical regime of life during the winter months. We undoubtedly eat too much strong animal food, and too little vegetables, take too little exercise to correspond with a strictly healthy condition; in short, we pamper ourselves, as it were, during the winter, and spring confronts us with its hard labor, only to find us like a race horse under similar conditions, good for a short dash, but with no bottom to hold out. Hence it is that "spring bitters," "salts and sulphur," etc., are brought into such common use at this season. If we are to continue in our old manner of life, then the theory of their use is good; and, among the best of these, is undoubtedly the common "blue mass," which arouses the lagging secretions of the system, setting the tearing down workmen busy at work, and if then followed by a good tonic such as cinchona (Peruvian) bark, calayaia, etc., to help the building up forces of the body to do their work, will no doubt do much towards warding off these spring attacks. But, it seems to us, the true theory is prevention, by eating more vegetables, taking greater care that the normal secretions are not interfered with by colds, and giving ourselves plenty of exercise and recreation during the tedious, chilly winter months.

Poisons and their Antidotes.

Mr. G. C. Rockwell communicates the following to the *Scientific American*: Fatal results of poisoning are most frequently occasioned by delay in applying, or by ignorance of, the antidote. The following is a list of the antidotes of the common poisons, and I suggest that chemists, druggists and others who are brought daily in contact with poisonous substances, post this list in some conspicuous place in their laboratories.

For alkaloids, such as morphine, quinine, etc.: Emetics and the stomach pump must be relied upon rather than chemical agents. Astringent liquors may be administered, such as tannic acid, which precipitates many of the alkaloids from their aqueous solution, absorption of the poison being thus retarded.

For antimony (tartar emetic, etc.): Any form of tannic acid may be administered (infusion of tea, nutgale, cinchona and oak bark, or astringent solutions or tinctures), an insoluble tannate of antimony being formed. The stomach pump must be also applied as speedily as possible.

For arsenic (Paris green, etc.): Recently precipitated moist ferrous hydrate, best administered in the form of a mixture of a solution of perchloride of iron with carbonate of soda. Emetics should be also given, and the stomach pump applied.

For copper (verdigris, etc.): For an antidote, administer iron filings, also white of an egg (albumen), which forms with copper a compound insoluble in water. Apply the stomach pump.

For hydrocyanic acid (cyanide of potassium, etc.): A mixture of green sulphate of iron, solution of perchloride of iron, and either magnesia or carbonate of soda, is the recognized antidote in cases of poisoning with prussic acid. Inhalation of ammonia is also advised.

For lead: Administer a solution of Epsom salts or alum, and induce vomiting.

For mercury (corrosive sublimate, etc.): Swallow the whites of several eggs. Albumen gives a white precipitate with salts of mercury, which is insoluble in the juices of the stomach.

For oxalic acid: In cases of poisoning with oxalic acid or salts of sorrel, chalk and water may be administered as a chemical antidote, with the view of producing the insoluble oxalate of lime. Emetics should also be applied.

For tin: In cases of poisoning by tin salts (dye's tin liquor), solution of carbonate of ammonia should be given. White of egg is also said to form an insoluble precipitate with compounds of tin. Vomiting should also be speedily induced.

For zinc: Large doses of zinc, fortunately, act as powerful emetics. If vomiting has not occurred, or has taken place apparently to an insufficient extent, a solution of carbonate of soda (common washing soda), immediately followed by white of egg and demulcents, may be administered.

The poisons contained in tobacco smoke find a ready exit from the system; when inhaled during a period of fasting their injurious effect on the heart is apprehended.—*Lancet.*

AN OLD USE FOR HAMMERS.—"I remember," says a correspondent of the *Medical and Surgical Journal*, "that when I was very young, they used to raise blisters with boiled hammers. Old Dr. Twitchell of Keene (peace to his ashes) once wanted to blister some one in a farm house, far from home. He had nothing with him to do it with. He asked the wife to find him a hammer. The article was brought out, put in a tea kettle over the fire, and after the water steamed and bubbled well, he lifted it out and gently touched it to his patient, in half a dozen spots, over the seat of pain, with very positive effect. Boiled hammers were for many years used in that neighborhood for pleurisy; and every old lady knew nothing was equal to a hammer; and there was a long dispute whether it should be a claw hammer or not. I think the years finally conquered."

THE GROWTH OF CICATRICES.—Mr. W. Adams, in a paper read before the Medical Society of London, shows that scars made in childhood grow with the general growth of the body. He exhibited casts taken at different periods of life, in some of which a growth of an inch had taken place in six or seven years. After deep wounds, or when a portion of the skin has been destroyed, the cicatrix appears to remain through life. The only ones that disappear are those resulting from superficial cuts, which do not penetrate fairly through the deeper layers of the skin.

The Gatling Gun.

Last fall one of the most wonderful trials to which any implement has been subjected, took place. According to reports made at the time, the Navy Department, in order to determine the quality of the solid head metallic cartridges, and to test the working powers and durability of the Gatling gun of .50-inch caliber, ordered that one hundred thousand cartridges of .50 caliber (containing United States service charge) be fired in the gun at Fort Madison, near Annapolis, Md. The trials commenced on October 23d, and lasted parts of two days. On the first day (the 23d) over 30,000 rounds were fired; and on the 24th, 64,000 cartridges were fired, without stopping to clean barrels; and after this unprecedented test, the gun (without the barrel being cleaned) was fired for accuracy at a target 12 x 12 feet, placed 300 yards from the gun; and out of 30 shots fired, 29 of the balls hit the central part of the target, striking point on and giving good penetration. It may be safely said that this number of discharges was never before made from any arm in the world.

Singular as it may appear, the fouling of the barrels did not increase after 4,000 or 5,000 rounds had been fired. The trials were made under the supervision of Lieutenant Commander J. D. Marvin, United States Navy, commandant of Fort Madison. Many distinguished navy and army officers were present at the trials. During a part of the trials, the gun was fired at the rate of 400 shots per minute. A drum which supplied the cartridges to the gun, and which contained 400 cartridges, was frequently exhausted in from 50 to 55 seconds.

Of the cartridges used, none of the heads burst, none of the shells failed to extract, and there was only one misfire in about five thousand cartridges discharged. The cartridges are headed by a new process, which prevents injury to the fiber of the metal from compression.

MACHINE FOR REDUCING STONE.—A new grinding machine of ingenious construction, and which acts with great power and efficiency, has been invented in England, its design being to reduce hard substances, such as rocks of granite, silica and other materials, to a finely pulverized state. The size at the mouth is twelve by five inches, and any stone of that size is quickly reduced by its action. The moving jaw is swung from below on a stout cross-pin, to the two sides, and is made so that it has the greatest motion at the top, and the least motion at the bottom. The toggles are worked from an upward connecting rod, actuated by a steel eccentric shaft, running in an anti-frictional metal bearings near the sole plate. The usual wedge motion and spring rod for bringing back the jaw are supplied, and the whole mounted on a foundation plate. An improved mixing apparatus is attached, by means of which the stuff is immediately and thoroughly blended, as it is delivered from the spout.

NEW STEAM AUXILIARY.—A new invention by Mr. J. Berger Spence, of London, consists in passing steam at ordinary atmospheric pressure into a solution of caustic soda, which is thereby raised to its own boiling point. It is proposed to use the heat thus developed to generate steam, the waste steam from an engine boiler being employed in the first instance to heat the caustic soda. Mr. Spence showed that the effect was absolutely produced by raising a solution of caustic soda to a heat considerably over 212° by means of a jet of steam, but he stated that he had not yet worked out practical details as to the employment of the idea, though he exhibited a sketch of an arrangement of boilers which he considered might render it available.

CEMENT FOR AQUARIA.—An adhesive cement for aquaria may be made, according to Klein, by mixing equal parts of flowers of sulphur, pulverized sal ammoniac and iron filings, with good linseed oil varnish, and then adding enough of pure white lead to form a firm, easily worked mass.

TABLE OF CONTENTS.

GENERAL EDITORIALS.—Cazin's Automatic Continuous One-Plunger Jig, 321. Astronomical Expeditions: The Island of Aruba; Academy of Sciences: Re-working Abandoned Mines; Mineral Land Decision; Notices of Recent Patents; The Failure of Parke & Bowie, 328. Work on Mining Claims; Stove Lid-Lifter and Stand; Monson's Gimlet Screw Bit; The San Juan Country, 329. Patents and Inventions, 332.

ILLUSTRATIONS.—Cazin's Automatic Continuous One-Plunger Jig, 321. Monson's Gimlet Screw Bit; Stove Lid-Lifter and Stand, 329.

CORRESPONDENCE.—Mining in Pimas and Sierra Counties, No. 7; Undeveloped Resources, 322. **MECHANICAL PROGRESS.**—Paper Box Making Machine; The Marvels of Mechanics, 323.

SCIENTIFIC PROGRESS.—The Astronomical Event of the Century, 323.

MINING STOCK MARKET.—Table of Daily Sales and Prices and Comparative Prices for the Week; Notices of Assessments; Meetings and Dividends; Review of Stock Market for the Week, 324.

MINING SUMMARY from various counties in California and Nevada, 324-5.

GOOD HEALTH.—"Spring Biliunness;" Poisons and their Antidotes; An Odd use for Hammer; The Growth of Clearing, 327.

USEFUL INFORMATION.—Black Varnish for Zinc; How to Varnish; To Clean Paint; Glycerine for Preserving Fruit; Incombustible Finish for Woven Fabrics; To Inventors, 327.

MISCELLANEOUS.—The Missouri Quicksilver Mine; Why Many Mining Companies Fail; 323. Earnings and Costs; Gwin Mine; Tybo District; Agricultural and Mineral Lands; Newfoundland District, 326. The Gatling Gun; Machine for Reducing Stone; New Steam Auxiliary, 327. The Depression in Cornish Mining; Miners Smoked Out; Cornucopia District; The Washoe Coal Mine; Mines of Western Nevada; Sticksen Mines, 330.

The Astronomical Expeditions.

Three of the eight parties to be sent out by the Government to observe the transit of Venus will leave Washington about the 1st of July for California overland, where they will take the mail steamer for Japan, there be met by the U. S. steamer *Lackawanna*, of the Asiatic fleet, and conveyed to their stations. The first party, in charge of Professor Hall of the Naval Observatory, will be stationed in Siberia; the second, in charge of Professor Watson of Ann Arbor, Michigan, at Pekin; and the third, in charge of Professor Davidson, of the Coast Survey, at Nagasaki. Each party will consist of an astronomer, assistant and three photographers. The following is a list of the heads of American expeditions for observing the transit of Venus, and their stations: Northern stations—Wladivostok, Siberia, Professor A. Hall, United States Navy; Nagasaki, Japan, George Davidson, United States Coast Survey; Pekin, China, Professor James C. Watson, of Ann Arbor, Michigan. Southern Stations—Crozet's Island, South Indian Ocean, Lieutenant-commander George P. Ryan, United States Navy; Hohart Town, Tasmania, Professor William Harkness, United States Navy; New Zealand, Professor O. H. Peters, of Clinton, New York; Chatham Island, South Pacific, Edwin Smith, United States Coast Survey.

The discovery of gold deposits in the bed of the Jefferson river, Montana, is creating quite an excitement. About ten miles of the river is already taken up in claims of 400 feet each, up and down the river, and from shore to shore.

Wool has become very scarce around Grass Valley and Nevada, and has to be hauled from six to eight miles. A company has been formed for the purpose of building a flume into the timber region, so that a supply can be floated.

The San Joaquin river is rising rapidly, and steamers now experience no difficulty in navigating as far up as Firebaugh's ferry.

All the mills on the Carson river and elsewhere in that section, except those undergoing repairs, are running full blast.

The borax mine at Lower Lake has suspended operations on account of the reduced price of that product.

The weather at Grass Valley is quite hot nowadays, and the thermometer frequently scores 80° in the shade.

The Island of Aruba.

This little island bids fair to become quite famous for its gold product; mining operations having already been commenced there on a large scale. The island is situated just off the northwest coast of Venezuela, in lat. 12° 49' N. and long. 70° 5' W. from Greenwich. It is about 20 miles in length and from five to seven in width. Syenite is its prevailing rock. Granite, greenstone and elates (diomite and talcose) occur to some extent. A belt of limestone (coral) from five hundred feet to a mile in width surrounds the island. The surface of the island is mountainous or hilly, the greatest elevation being 600 feet. Aruba is sparsely wooded. The chief articles of export are aloe and peanuts. A species of corn called by the natives *mice*, much resembling hroom corn, is grown for food. The climate is uniform, the thermometer in the shade or at night time never falling below 78° or rising above 92° Fah. The trade winds blow from 15 to 20 miles an hour for nearly ten months a year. Two hundred and upwards gold-bearing quartz veins have been discovered on the island. These veins are well defined; some of them quite large. One is 23 feet in width. They prospect well—gold being found by panning nearly every time.

The mineral resources of Aruba have been conceded for a term of 35 years to the Aruba Island Gold Mining Company (Limited), the stock of which is owned in London and New York. The company have erected a California 20-stamp mill to run by six Empire wind-mills—their wind-wheels being 35 feet diameter each. Salt water is used for milling purposes. There are as yet but two stamps running, which crush about 20 tons of rock per day—the rock thus far has paid \$20 a ton.

Prior to the concession of the mines to the company, some veins were worked by the natives with highly gratifying success. They treated none of the rock in which gold could not be seen by the unaided eye. The rock was broken to the size of wheat grains, then placed on a flat rock and mulled by hand, with a stone weighing thirty pounds or thereabout. The pulp was then washed in a calabash shell, (sort of a gourd shell). The amount of gold thus taken out was estimated to be nearly a million of dollars. There are about 5,000 inhabitants on the island. These consist of, say 200 whites of Dutch origin, 500 negroes, formerly slaves, (slavery was abolished about ten years ago), 500 Indians, and the balance of a mixture of various shades of color. The standard wages are thirty cents a day without board. The inhabitants are a kindly disposed and docile people. We have gathered the above facts from a conversation with, and from the written reports presented to the company by Mr. P. M. Randall, a mining engineer, formerly of this city, but now of New York, and on a visit to San Francisco.

Academy of Sciences.

The regular meeting of the California Academy of Sciences was held on Monday evening last, Vice-President Hewston in the chair. Robt. T. Van Nardou and Rev. D. L. Green were elected resident members.

The contributions for the evening were principally comprised in a large and valuable botanical collection, from Professor H. N. Bolander, embracing two packages of plants from the Cape of Good Hope and four packages from Europe.

G. W. Michael, Jr., presented silicious petrifications of roots, from San Luis Obispo county.

S. R. Throckmorton presented a specimen of *Rhinobatus Productus*, caught in the bay of Black Point. This curious fish is described by Mr. Ayers in the second volume of the proceedings of the Academy.

Henry Edwards presented 26 specimens of crustacea, from the coast of Mexico.

A specimen of petrified oak, found 100 feet below the surface, at Dutch Flat, was presented by a member.

The Curator, H. G. Bloomer, made a valuable addition to the library, in the presentation of seven volumes of the "Phytologist," a standard botanical work.

The only matter of general interest occurring at the meeting was when a member submitted for inspection shells of the Eastern transplanted oyster, which were covered with the spat of young oysters. It was a question whether the spat was that of the native California oyster or the propagation of the transplanted bivalve, and oystermen, whom he had consulted, were unable to determine the point. Mr. Throckmorton, State Commissioner of Fisheries, stated that he had investigated the matter, and found that the spat was that of the California oyster. It was found on the shells of Eastern oysters only where they had been transplanted in the vicinity of native beds. As yet the Eastern oyster had developed no tendency to increase in these waters. They were short-lived here, becoming very fat, and dying within a year after being placed in the bay. The experiment of transplanting Eastern oysters must, therefore, be deemed a failure.

A man named Wright last week struck a \$450 pocket in a quartz ledge, near Altaville, Calaveras county.

The Columbia claims, Tuolumne county, are expected to yield \$200,000 this season.

Re-working Abandoned Mines.

We regard it as a sign of benefit to the mining interests that in many localities in this State claims abandoned years ago are now being worked again. In the early days of quartz mining in California extravagance was the rule and economy the exception. Expensive mills were erected in many instances before any work was done on the ledge which was to furnish the rock, and large amounts of money spent before the claims were even prospected. Naturally, under these circumstances, there were hundreds of cases of failures in quartz mining, and the mines themselves fell into had repute. Of late, however, these facts have been recognized, and many of these abandoned claims have been bought up or re-located by parties who know something about the business of mining and milling, and who can make the claims pay. Comparatively cheap labor, cheap transportation, a better knowledge of mining and other circumstances combine in favor of these new locators, and most of them are doing well.

We mentioned recently that work was to be resumed in the Stanislaus-Melones mine, in Calaveras county, and only lately work was commenced in the old Mina Rica de Las Flores mine, near West Point, in the same county, by a new company, known under the name of the Enterprise Consolidated Gold Mining Company. The old Mina Rica mine was worked to some extent in 1863 and 1864, and considerable very rich rock was extracted. The old story of extravagance, however, sealed up this mine, as it has done many others. They put up a ten-stamp steam-mill, with seven pans all complete, and costing about 67,000. This operation burst up the company, and no further work was done on the mine, although the experts employed told the owners that by sinking 30 or 40 feet the three quartz veins which they were working would be found to unite in one. The ore yielded from \$50 to \$75 per ton, and they could raise some 20 tons per day. However, the owners spent so much money that the company broke up, were sold out, and the mill was moved away about seven years ago.

The new company owning the mines started up work recently and have sunk a new shaft 82 feet, the old one being choked up, caved in and otherwise unfit for use. Assays of the ore they have taken out run from \$127 to \$600 per ton, and they think they will be able to get plenty of ore that will mill \$100. They have made arrangements to get this ore crushed at a custom mill near by, the crushing and hauling costing \$6 per ton. A boiler and engine are being put up on the mine for pumping and hoisting, but the mine must pay for other improvements before they are put up. The company propose to sink 50 feet deeper before they begin to run a level. They are going to have the ore crushed, that they have already taken out while sinking the shaft. The same company also own three other mines in the same vicinity—the Jacobs lode, Maria No. 1 and Maria No. 2. They are sure that they can make the Enterprise mine pay, as they have got the rock in sight to do it with.

Mineral Land Decision.

The Register and Receiver for the San Francisco Land District recently sent to the Land Office three quicksilver mining claims, commending them to be patented. They are known as the Andy Johnson, Fourth of July and Boston, and are situated in Monterey county, California. The claimants are C. J. P. Sargent, A. J. Sargent, Thomas Flint and Benjamin Flint of Monterey county. The three claims embrace an area of 28,840 feet, and are said to be valuable.

Wm. McGarrahan appeared in person and by counsel before the Department, to resist these applications. The following is an abstract of his argument in opposition to applicant:

First—That the patent claimed to have been executed to him by President Lincoln, March, 1863, vested the legal title, and that said claims being within the boundaries of said patent, they were his private property.

Second—That at the end of 1867, when those officers surveyed and made publication of these mining claims, a resolution adopted in the House of Representatives, forbidding any action to be taken by the Interior Department that would in any way affect McGarrahan's title to this property, was in full force.

Third—That the Commissioner of the Land Office, in accordance with the terms of said resolution, instructed Mr. Upson, United States Surveyor-General for California, and the Register and Receiver, to allow no action to be taken by them that would in any way affect McGarrahan's titles.

Fourth—That these officers, in defiance of said resolutions and instructions, took action and had a survey and publication made, and advise that patents should be given to the above parties for 28,840 feet, when the mining law of July, 1866, only allowed 200 feet to each locator, and 200 feet additional to each discoverer, and the maximum extent of 43,000 feet to each company.

Fifth—That the Hon. W. P. Smith, Assistant Attorney General, decided in New York case, that said resolution and said instructions, suspending all action should be respected, and that no more than the number of feet above stated could, in any event, be patented to either a person or company.

Sixth—That the time required by law for applications was not complied with.

The Hon. M. W. Curtis, Acting Commissioner, rejected all of the above claims, and directed the Register to that effect a few days ago.

A MEXICAN miner picked up a "chispa" of gold recently, weighing thirteen ounces, in the creek near Hornito.

Notices of Recent Patents.

Among the patents recently granted to Pacific Coast inventors, through Dewey & Co.'s Patent Agency, the following are worthy of mention:

REIN HOLDER.—Jefferson Kindleberger, S. F., Cal. This invention consists of a metal plate, having a projecting rib extending lengthwise along one side and short standard at one end. A shaft is secured in the upper end of this standard parallel with the rib, and a concave plate is secured loosely on this shaft. The reime are slipped between the concave plate and rib and are held by the crimp thus produced and by the binding of the edge of the concave plate.

HYDRAULIC MAIN AND RETORT CONNECTIONS FOR GAS WORKS.—James R. Smedberg, S. F., Cal. Relates to an improved construction by which the flow of gas is rendered clearer and less liable to become clogged by an accumulation of tar. It also consists in the construction and union of the stand and dip pipes connecting the retort with the hydraulic main, so that the openings of both pipes are accessible for cleaning by removing one plug, and the construction is such that any luting that may fall into the pipes will be conveyed directly to the retort mouth, where it can be easily removed.

PERMANENT FAUCET FOR BEER BARRELS.—John Brizee, Alvarado, Cal. Mr. Brizee thinks that too much good beer is wasted in securing the ordinary faucet in beer barrels. He has therefore provided a neat attachment which is permanently secured to the cask or barrel so that the beer can be drawn at any time without waste. It is a neat device and will greatly reduce the trouble of brewers in keeping their faucets in good condition and will be a great convenience to consumers.

GARDEN SPRINKLER.—Nathaniel Clark, S. F., Cal. This invention is not only useful but it is ornamental. It consists of a semi-globular nozzle-head so constructed that the pressure of the water in the nozzle sends it spinning in a wonderful fashion, and as the head is perforated with numerous holes the water is thrown in a spray in every direction. It is intended for watering lawns, grass plots, gardens, etc.

ORE STAMP FEEDER.—Thos. A. Cochran, S. F., Cal. This invention consists of a revolving table which is placed at a slight incline. The ore is fed by a hopper upon the table, and the table is rotated by suitable connections with the tappet on the stamp stem. Suitable guides direct the ore into the battery.

PROCESS AND APPARATUS FOR SUPPLYING CITIES WITH MILK.—Frederick T. Newberry, S. F., Cal. Mr. Newberry proposes to lay a pipe from some point or depot in the country where milk is plenty and cheap, and extend it to a depot in the city. He will employ a suitable pumping engine to force the milk through the pipe into the city. When the pipe is not in use conveying milk, it is kept filled with water, the water and milk being alternately forced through the pipe as required.

The Failure of Parke & Bowie.

Last week the property of the well known tailing-mill men, Parke & Bowie, was sold by the assignees in bankruptcy, in Virginia, Nevada. At the sale, the Railroad tailings-mill in Six Mile cañon, with boarding and lodging house, shops, reservoirs and tailings flumes, with land in both Six and Seven Mile cañons, was sold for \$15,250. The mill and appurtenances cost originally \$130,000.

The Empress tailings-mill in Six Mile cañon, a short distance below the Railroad mill, was sold for \$5,400. It originally cost \$70,000.

The private residence of Ira S. Parke, with a coal tar reservoir, tailings reservoirs, sluices, orchard, nursery, and considerable land was sold for \$3,000. The residence cost about \$60,000.

The whole amount of indebtedness proved up against the estate in bankruptcy court was \$175,000; then there were about \$25,000 in liens or mortgage. There are probably \$10,000 in debt not proved up. Altogether the indebtedness amounts to about \$210,000.

The amount realized by the late sale was \$67,065. By a former sale of teaming horses and the like, about \$8,000 were realized, making a total of \$75,065.

The total first cost of the property sold was over \$300,000.

The property owned by these gentlemen was very valuable. The mill worked over old tailings from the quartz mills, and at first made a very profitable business of it; but when quicksilver rose to the present prices they were unable to work at a profit. The *Territorial Enterprise* thus describes the cause of bankruptcy: "The failure of this firm was directly caused by this sudden, unlooked-for, and almost unexampled rise in quicksilver. At the time when they built their mills, constructed their flumes and reservoirs, and made their many other extensive and costly improvements, quicksilver was selling at 60 cents per pound, and the millions of tons of tailings they possessed, and were constantly accumulating, could be worked to a profit. The rise of quicksilver from 60 cents to \$1.30 per pound, more than double the price that entered into any of their calculations for working tailings, was a death-blow to all their enterprises."

PROSPECTING on the hills immediately around Pioche and its neighborhood is being resumed to a considerable extent.

Work on Mining Claims.

The miners of the coast are all of them probably well aware by this time of the proper steps to be taken to hold the claims which they are not actively working. We have explained the law on the subject repeatedly of late, so that our mining readers might have their attention called to the fact that they must do the required amount of work in time to hold their claims. The time, as extended, is fixed at the 10th day of June, 1874.

Efforts have been made to have this time extended, as we have noted before, giving the bill introduced in Congress in our last issue. The Senate committee on mines and mining have reported favorably on this bill, but as yet Congress has taken no action on it. It behooves our mining friends, therefore, to be thoroughly prepared to begin their work on the 10th of June, if not before, in order to hold their claims.

There is some question as to whether this law, requiring a certain amount of work to be done every year, applies to placer as well as lode claims. We have in a convenient form all the decisions of the Commissioner of the Land Office, under the new law, and there is no mention of the matter to be found. Lodes only are specified. Parties with whom we have conversed are divided in opinion on the subject, and it must, of course, be left to the decision of the Land Commissioner in the end. However, to be on the safe side, owners of placer lands had better consider themselves in the same light as if owning lode claims. An important question like this should have been decided long ago, one way or the other, as, if the law applies to placer claims and owners do not do the work on them, they are liable to lose their claims; and, if the law does not apply to placer claims, and the owners do work them, it is rather unjust for them to expend money unnecessarily. It should have been clearly specified in the law itself.

Stove-Lid Lifter and Stand.

The accompanying cut represents a convenient little instrument, recently invented by Samuel Hill, agent of the Florence Sewing Machine Company in this city, and patented through the Agency connected with this office. The implement is intended for handling stove-lids, and at the same time forms a stand by means of which the lid, when attached to it, can be held in an upright position, so that it can be placed upon a carpeted or other floor, without soiling or marking it.

The implement is very simple, as the cut shows, and is convenient for lifting stove-lids from one place to another, in place of the ordinary stove-lid lifter. The handle furnishes a convenient means of grasping the implement, and when made of wood will not be as liable to become heated as metal handles. A shield can be applied between the handle and attached stove-lid, if desired, to prevent the hand from being burned by the heat of the lid.

Besides being an ordinary lid-lifter, when the lid is lifted upon the hook, the stand can be set down upon a floor, shelf, or other place, so as to rest upon the foot of the base and the end of the handle, in the position shown in the cut, thus supporting the lid without allowing it to touch the floor. The implement can also be used for lifting pots from the stove, as the hook can be caught under the bail, and the pot lifted without touching it with the handle.

Turbine Water Wheels.

The following letter explains itself:

EDITORS MINING AND SCIENTIFIC PRESS.—We noticed in a late number of the SCIENTIFIC PRESS a so-called "challenge," copied from the Dayton O., Journal, and published as an advertisement by a firm in this city, which is an answer to a challenge made by Jas. Leffel & Co., of Springfield, O., to Messrs. Stout, Mills & Temple, to test their wheel (the American Turbine) with the LEFFEL Wheel by grinding grain or driving any kind of machinery. They, after some weeks' careful study, replied in the language of their "challenge," "We will under no condition spend time testing water wheels in competition with any one by grinding grain or driving any kind of machinery." They were immediately answered by Jas. Leffel & Co., and challenged to enter into a competent test, and said challenge has been standing now over six months and has not been accepted. If, however, the firm in San Francisco wishes to accept the challenge made by Jas. Leffel & Co. to make a practical test of their wheels against ours, we will hold ourselves personally responsible to all of its demands.

We will in a short time give a full history of water wheel tests recently made, and in the meantime all wishing to be informed of the handy practices of "competent engineers" will be fully enlightened by addressing the undersigned at Salem, Oregon, or at 306 California street, San Francisco, California.

LEFFEL & MYERS.

Reports from the Schellburn district are favorable, and indicate a prosperous season. The McMahon mill, the first in the district, commenced operations on the 8th instant, and is running to its utmost capacity on good paying ore.

CHINAMEN continue to arrive at the Lava Bed mine, near Croville, in great numbers. It is estimated that before long there will be from 15,000 to 20,000 Chinese miners at that camp.

The shipments of lime from Santa Cruz to this city are very heavy, though hardly keeping up with the demand.

SANTA CRUZ is the last county in which quicksilver has been discovered.

Monson's Gimlet Screw Bit.

Wood-workers will appreciate the convenience of the implement shown in the accompanying cut, which is a form of screw bit, invented by Christian Monson, of Moscow, Iowa county, Wisconsin.

As will be seen by the cut the bit is made of three different diameters, corresponding to the variations in caliber of the wood screw so universally in use. The section next the point is made even smaller than the screw, to allow the thread an ample hold upon the wood, and yet to guard against the chance of splitting, as the middle portion is made enough larger to allow the blank part of the screw to drive easily and hold well. The larger portion, A, countersinks the wood for the head of the screw, or even sinks it to any desirable depth. It cuts smoothly, as it has a draw out. The style of Fig. 3, with the triangular awl joint, is calculated only for the very smallest sizes. Of the larger sizes, one bit can, of course, be used for boring three different sizes of holes through an inch board. The invention will commend itself, as it tends to bore and countersink in a perfect manner at one operation, making an improve-

MONSON'S GIMLET SCREW BIT.

ment in economy of time, labor and expense, and also in durability, as the last projection answers as a brace.

The patentee writes us that, having many other things on hand, he wishes to dispose of his patent on this bit, royalty preferred. He is also the inventor of an improved grain drill, shown in the *Scientific American* of February 14, 1874, and a three burr grist mill and a berry huller. He wants to dispose of rights for one, two or all three of his inventions.

HIGHT OF CERROS ISLAND—CORRECTION.—While the P. M. S. Co.'s steamer *Colima* was

Stove-Lid Lifter and Stand.

lying disabled off Cerros Island a party consisting of Messrs. P. M. Rendell, Mining Engineer; F. K. Balch, Ship Officer and E. Vogt, Artist, ascended March 23d, 1874, the highest point of the island, and determined it to be three thousand nine hundred and fifty feet in altitude instead of twenty-five hundred feet as two erroneous, which agreed perfectly at various points in the ascent from the level of the sea laid down on the coast chart. They made use of the summit. They named this Mount Hudson, after Captain Hudson of the *Colima*. On the highest peak, they erected a monument of stone, placing within, well protected from the weather, a card setting forth the date of ascent, name and height of the mount, with the signatures of the explorers.

The *Statesman* says two companies are at present prospecting in the coast mountains of Oregon, for gold, silver, cinnabar, etc. They have been in the mountains for some time, but as yet have not succeeded in discovering any indications of the precious metals, though large quantities of iron and coal have been found.

W. H. ARMSTRONG, formerly superintendent of the Sapphire quartz mill, has been appointed superintendent of the Woodworth mill, on the Carson river.

CONSIDERABLE mining property is changing hands in Utah.

The San Juan Country.

An Accurate and Comprehensive Description by One who has Seen it.

The new mining region known as the San Juan country, lies in southwestern Colorado, on what was recently the southern part of the consolidated Ute reservation. By a recent treaty something more than three millions of acres was ceded back to the United States. It straddles the Sierra Madre, or main range of the Rocky mountains, and forms the hub of numerous diverging mountain spurs, including the Uncompahgre and San Juan ranges, Sierra, San Miguel and Sierra La Plata. It comprises four distinct slopes, or water sheds—the northern or Uncompahgre, the eastern or Rio Grande, the Southern or San Juan, and the western or Utah slope. In this respect it is remarkable in the topography of Colorado, as well as of the American continent. It is topographically and literally a continental emmit; one of the principal apices of the Rocky mountain system.

The Streams Which Drain the Region

Are all, as a consequence very rapid and frequently interrupted by cataracts of considerable fall. The principal of these are on the

northwest and north; the Rio San Miguel, Uncompahgre, Dallas Fork, Uncompahgre, and Lake Fork, of the Gunnison, all tributaries of the Gunnison and Grand rivers; on the east the Rio Grande del Norte and tributaries, flowing into the Gulf of Mexico; on the south the Rio San Juan and its numerous boundaries, including the Navajo, Piedro, Los Pinos, Florida, Animas, La Plata and Mancos; and on the west the Rio Dolores, also a tributary of the Grand. All the streams mentioned have their origin within a radius of fifteen or twenty miles from a common center, and all except the Rio Grande del Norte have their final outlet through the Great Colorado of the west into the Pacific. Hence the group of new mining districts, comprehensively known as the San Juan mines, be on the Pacific slope of the continent, with the single exception of the Summit district, which occupies the summit of the divide between the San Juan and the Rio Grande slopes.

In this portion of Colorado

The Main Ranges of the Rockies—Cordillera del Sierra Madre.

Is very much broken up and interrupted in its prevailing direction. None of the many spurs yet extent give any thing more than vague guesses at the real topography. The central chain sweeps abruptly to the westward from the southern extremity of South Park, crosses Saguache county, where it takes the local name of Saguache mountains, and reaching the head of the Rio Grande it abruptly divides into many spurs, the principal one bending southward, forming the main Atlantic and Pacific watershed, and again deflecting to the southeast becomes the San Juan range proper. The other spurs are the Uncompahgre mountains, the Sierra San Miguel and the Sierra La Plata.

It is as if the great rocky backbone of the continent had here bent upon itself, by some awful throes of nature, until its monster contortions broke asunder and overlapped each other. This explains the unparalleled abruptness of the region and the occurrence of so many elopee and counter slopes within a comparatively limited area. The surface of the whole region is pre-eminently mountainous and the extreme ruggedness of the mountains the most noticeable feature. On every hand sharply outlined snow-peaks pierce the clouds. Temese is an unknown element in the landscape. Everything is angular, abrupt and immense.

"—Sierras and eternal tents of snow
That flash o'er battlements of mountains."

All the valleys are consequently narrow, and the parks—so called—are scarcely worthy the name, being no more than the occasional widening of the valleys, as if by accident.

The prevailing

Geological Formation

Is granite, or some of its numerous variations—evenly being the most frequent of these. This argues well for the permanency of the mineral lodes of the region.

The upheaval has been both extensive and uniform, and the veins are almost invariably vertical. The prevailing trend, as shown by the lodes thus far recorded, is northeast and southwest; but a considerable number extend in a direction nearly at right angles to this.

Certain geologists who have cursorily and theoretically studied the region, venture the opinion that here is the junction of two well-defined mineral belts, viz: the Colorado belt proper, extending in a northeasterly and southwesterly direction across the Territory, from Wyoming or North Park to Arizona, and so on to old Mexico and the Pacific coast; and the Utah belt stretching somewhat interruptedly from western Montana and Idaho, in a southeasterly direction through Utah, across the southwest corner of Colorado into central New Mexico, terminating in the Cimarron and Moreno mines. According to this theory the mineral-bearing ranges outside these two main belts are auxiliary feeders or accidental spurs. Further and more accurate data are wanted to fully establish this theory, but facts already known give it a strong coloring of plausibility.

The Original Discovery of Gold

In the San Juan country by white men occurred in 1860. But the region was then so remote from civilization that the first crazy expedition, under the leadership of a noted mountaineer by the name of Baker, failed to realize any satisfactory results. They made no search for lode deposits, being wholly bent upon finding rich placer diggings, which existed, according to both Indian and Mexican tradition, along the tributaries of the San Juan. Exhausting their meager supply of provisions, the party scattered in all directions, some perishing at the hands of hostile Indians, others dying of starvation, and others escaping down the Rio Grande, as it were by the skin of their teeth, to tell the sorry tale of failure and suffering. Various causes—including the setting apart of the western portion of Colorado as an Indian Reservation—have operated to prevent the exploration of the region. Faith in the ultimate discovery of fabulously rich mines here has never flagged. Years after the Baker fiasco, the proprietor of the mail route between Santa Fé and Los Angeles, in California, accidentally encountered new proof of the

Existence of Precious Metals

In this vicinity. His name is Stewart and he is now a resident of Taos, in New Mexico. He recounts his adventures as follows:

Accompanied by a young Mexican boy, he was making the hazardous journey across the desert without other escort. A few days out from Santa Fé he was met by a small band of Navajoes, who told him they were then in active war with the Apaches, and that he would be certain to be intercepted and murdered by the latter bloodthirsty tribe unless he turned aside from the usual trail. They directed him to bear to the right for two days, which would leave the unfriendly tribe to the southward and avoid all danger of meeting them. He followed the advice, and on the second day while halting on the banks of a beautiful and rapid mountain stream, to dispatch his noonday meal and bait his animals, the Mexican boy, with the curiosity common to boys of whatever nationality, played in the stream and gathered pebbles from its sandbars. Having previously seen something of placer diggings, he discovered signs which induced him to wash some of the sand in a mess-pan. The result astonished both parties. During the noonday he washed out eighteen dollars in golden nuggets, which he carried to Los Angeles and disposed of to the British Consulate stationed there. Stewart had no very definite idea of the locality, but believed the stream at that time was known as Eagle river. From his descriptions and statements it would appear to have been either the Rio La Plata or the Mancos. He has made several recent attempts to find the locality again, but without success. The Mexican boy, who is now man-grown, does not agree with Stewart in his opinion of the whereabouts of the lost El Dorado, and is confident that during the coming season he can conduct a party to the identical spot, where he made his first stake by panning out eighteen dollars in half an hour.

Discoveries of Quartz.

In 1870, lode-prospectors invaded the head of the Animas, by way of Tierra Amarilla and the old site of the Baker party's Animas city. They found mineral veins cropping out on every hand, and brought away samples from a few of the more promising ones located. One of these proved to be immensely rich in free gold, and the subsequent development of this lode has given the San Juan country its substantial reputation. Assays of the ore have returned all the way from \$100 to \$30,000 per ton, and the working results by means of very imperfect apparatus, have averaged as much as \$1,200 to \$1,500 per cord. Although at first reported to be a gold region, further investigation shows that silver is by far the predominant mineral. The number of silver lodes recorded amounts to thousands, while those containing gold in any paying quantity do not number a score.

Baker's Park, a widening of the upper Animas valley, named after the leader of 1860, is the

Center of the Present Excitement.

It is rimmed round with steep mountains, which are thickly and visibly seamed with mineral veins. As compared with those of other mineral-producing sections of Colorado, the distinguishing characteristic of the San Juan lodee are:

1. Far more extensive out-cropping: Most of the veins yet discovered may be traced on the surface of the mountains for long distances—sometimes for miles.

2. Greater width: In some instances this is so great that any statements approximating the

(Continued on page 332).

The Depression in Cornish Mining.

For several months past mining in Cornwall has been in a state of depression which is almost without parallel in the history of the Duchy. A slight reaction has lately commenced to set in; but, though it may be looked upon as an augury of good for the future, the loss already sustained will require, even under the most favorable circumstances, a very considerable period for its evil consequences to be overcome. At the time when the change for the worse commenced, Cornish mining was enjoying a state of great prosperity. The prices of its chief products, copper and tin, were commanding unusually high prices. Speculation had set in on a great scale simultaneously with the commencement of the rise. The markets became unduly inflated, and fictitious values were established by sales which had existence only on paper. Foreign production was thus fostered by the high quotations which were reached. Supplies of ores and metals poured in from all quarters. So sudden was the increase of stocks thus produced, and so great the dread that it was only the presage of still greater importations, that a fall immediately took place, and sales were suddenly checked. Speculators who had been dealing on credit, and who never contemplated completing the purchases they made, but counted only on receiving differences, found themselves saddled with contracts they could not carry out in the face of a falling market. A panic was the result. The metal markets, which had been buoyed up by worthless paper, collapsed, and prices declined with a rapidity great in proportion to the suddenness of the increase which had previously taken place. About this time the prices of coal, material and wages began to rise, until the famine point, from which all branches of industry are now suffering, was reached. Our mines in Cornwall had thus to meet a foreign competition never previously known, under conditions of difficulty which had never before been exemplified. That they have been able to resist in so far as they have done the immense strain thus put upon them is a proof of their real intrinsic merit, and gives the best grounds for anticipating that when affairs shall have returned to their usual channel they will again become sources of national wealth. One point is clear, that if prices were to continue at figures which make profitable mining in England impossible, with all the advantages we possess in fuel, mechanical appliances and skilled labor, it will only, be in very few instances that foreign producers will be able to continue exporting to us, with all the disadvantages they labor under of heavy freights and the want of those very essentials in which we are rich. That this is already beginning to be felt is clear from the news received from the tin districts of Australia, where the stream tin mines, whose working is the least expensive that exists, are found not to be paying speculations at present prices, and are being for the time abandoned for more lucrative employments. What has taken place with regard to tin has done so also, to a certain degree, in copper, as is evinced by the late strike on the part of the copper miners reported from the same quarter. It is true that the difficulty is said to have been arranged, but its existence—caused, as stated, by a proposal to reduce wages—is a proof that the limit in price has been reached, if not passed; and at present rates it is out of the question for the miners in the colony to endeavor to compete with us in our own markets, and pay the freight for the long transportation their produce has to undergo before it arrives in this country.

Looking dispassionately at the present state of mining, both in Cornwall and other counties which produce copper and tin, it is evident that the existing state of depression in the former is the result, not so much of foreign competition as of a series of unfavorable circumstances in this country. All branches of trade and industry are alike suffering from the same causes. Mining, as being peculiarly sensitive to such influences, is doing so to a greater degree than most others. When the recovery begins to set in, as there is every appearance of its doing soon, though the settlement of the labor question may delay it for some short time, mining will at once begin to recover; but as we have called into existence a very formidable foreign production, we must set about introducing all those improvements and labor-saving appliances which may enable us to produce our ore at the cheapest possible rates. Many years ago, when Captain Trevethick introduced his great improvements into the pumping engines used in Cornwall, the mining of the Duchy was in a similar condition to that which it now is, with this exception, that instead of its being a passing nature it had become chronic. His varied inventions gave it new life. The same must be done now, and we need not fear for the future. To do so will no doubt cost considerable outlays of money; but when capitalists see fair prospects of handsome returns there will be no lack of funds for any legitimate purpose. In the meantime the fall in the prices of copper and tin has exercised a most baneful effect, as is shown by the great decrease in the value of shares in Cornish mines, which has taken place since the commencement of the year. There has been within the last fortnight a slight improvement in some instances, but for the purpose of illustrating the actual difficulties which have surrounded Cornish mining, this may for the moment be left out of the question. In looking, then, at a few of the best known mines, we find that Carn Brea has since the 1st of Jan-

uary fallen in market value 38½ per share, or 38,000 in all. The fall in Dolcoath has been 20½ per share, or a total of 80,000; East Pool, 30,000; South Caradon, 30,000; Tincroft, 110,000.—18½ 10s. per share; Trumpet Consols, 20,000. This mine in 1872 paid in dividends 8,000; last year it, however, returned no profits, and during the quarter just ended has been forced to make a call of 2,000. With regard to other mines, we find the difference in their present value to be—Cook's Kitchen, 17,000; South Crofty, 20,000; West Frances, 14,000; South Conduarrow, 15,000; Wheal Bass, 7,000; West Chiverton, 7,000. The above are amongst the most prominent instances, and give a fair specimen of the general depreciation which has taken place in Cornish mining property.—*Mining World*.

Miners Smoked Out.

The Kossuth and Alhambra mining companies, situated a short distance below Silver City, are now at war; are, in fact, in the midst of an irrepressible conflict. Last Monday the Alhambra broke through into the Kossuth, or the Kossuth into the Alhambra, we don't know which; but at all events the works of the two mines made an unexpected connection several hundred feet below the surface. Out of this grew a sudden unpleasantness; the two hitherto friendly companies "soured" on one another. As to what passages at arms may have occurred between the employees of the two companies, far down in the seething bowels of mother earth, previous to yesterday afternoon, we are not informed. About three o'clock yesterday afternoon, however, the followers of Kossuth opened active hostilities against the Alhambra. About that time the men in the Alhambra

Smelt Something Burning.

They were not long in doubt as to the nature of the fumigation. The odor wafted to them was not that of sandalwood, neither that of frankincense nor myrrh. What reached them was the hot, pungent, stifling smoke and gas which told them of burning pitch pine. The Kossuth men had secretly prepared and lighted in a drift of their mine, connecting with the Alhambra shaft, a large bonfire of pine wood. There being a draft into and up the Alhambra shaft, the men working therein soon found themselves in danger of suffocation, and made all possible haste to reach the surface.

A Narrow Escape.

Herman Scheel, the superintendent of the Alhambra mine, narrowly escaped losing his life. When he was hoisted to the top of the shaft he was asphyxiated to the verge of insensibility, and fell back, but luckily caught on the edge of some planks and held on long enough to enable those standing near to snatch him away. Had he fallen to the bottom of the shaft it would have been certain death, for had he not been been dashed to pieces by the fall, the smoke and gas ascending the shaft would have prevented any one going down to his assistance and he must inevitably have perished.

Turning the Tables on the Kossuthites

Was now tried by the men of the Alhambra, but with what success is not known. They covered the mouth of the Alhambra shaft with blankets, in order if possible, to force the smoke back into the Kossuth mine. The smoke still appearing to gather and thicken and pack in the Alhambra shaft, several barrels of water were got in readiness, the covering of the shaft was raised and all the water suddenly poured down upon the smoke. To what extent the smoke was thus driven back into the Kossuth is not known, but the chances are that they in the mine received a temporary hoist from their own petard.

The Alhambra Men to Have Been Blown up.

A deserter from the rank of the Kossuthites came over to the side of the Alhambra men yesterday morning and made known to them a scheme which had been proposed for blowing them all up. He stated that Mr. Walley, foreman of the Kossuth, had ordered him to drill a hole under where the Alhambra men were at work; put a heavy charge of giant powder into it, and when the enemy came to work to fire the charge. It seems almost impossible that any such fiendish idea as the wholesale slaughter of the innocent workmen of the Alhambra, could have been seriously entertained by the foreman of the Kossuth, yet the man who came from that mine assured the Alhambra folk that it was so, and further said that he quit work rather than obey the order. At last accounts last night the hostile forces were still in the field. How the war will end remains to be seen. The chances are that a battle will be fought either under ground or on the surface before all is over; then, whatever may be the result, there will be another set-to and final wind-up in the courts. The Alhambra mine is situated a short distance north and west of the Kossuth, and both mines are in close proximity to the Dayton mine and works.—*Enterprise*.

A VALUABLE MINE.—The Patriot mine, in Yankee Blade cañon, is turning out to be a first class mine. Its owner, James McCann, has worked it for several years, during which time it has more than paid its way; and recently he struck upon a ledge of two feet in width which contains ore of an average value of \$800. There are several tons now being reduced at the Manhattan mill, from which he expects to realize between \$7,000 and \$8,000, and when he gets his ledge fairly opened it will take but a short time for him to take out a fortune.—*Reese River Reveille*.

Cornucopia District.

Cornucopia district, which made such a stir a short time ago, has been little heard of lately. A correspondent of the *Sacramento Record* recently had something to say of the district as follows:

Cornucopia is situated in the northern portion of Elko county, on the headwaters of the middle fork of the Owyhee river, distant from the Idaho line some 25, and from the line of the Central Pacific railroad about 80 miles. Elko, Carlin, Paliade, Battle Mountain station and Winnemucca are all available as supply points. Within the circumference of the circle described, from this place as a center, with a radius of 25 miles, are embraced Tuscarora, Trail Creek, Ten-Mile Creek, Deep Creek, Bull Run, Cope, Murray, Caledonia, Bruneau or Wyoming, Mardis, Fairweather, Sooner and Island Mountain districts, all of which give promise of eventually becoming lively camps, the most prominent of which are Bull Run, Cope and Bruneau. The valleys and plains adjacent to the mining camps are eminently adapted to agricultural and grazing purposes. Cornucopia is the most recent discovery of the above named places, having been located in June, 1873. Its

Natural Advantages

Are, first, the character of the ore and country rock, the ore being unusually rich, free from base metals and not refractory in reduction, while the porphyry and decomposed quartzite in which the ledges are found is soft, through which works can be run at a comparatively trifling expense; second, the abundance of wood, water and grass—those adjuncts so necessary to a mining as well as a good camping ground; and, third, the cheap cost of labor, supplies and transportation to and from the line of the railroad.

The Prominent Mines

Are the Leopard, which is developed to a depth of 100 feet; the Chloride, opened up to a depth of 40 feet; the Constitution, shaft 50 feet deep; the Miner's Delight, down 120 feet; the Hussey, with shaft 80 feet deep; the Fisher, down 60 feet; the Monarch, shaft 30 feet and tunnel in 50 feet; the Black Diamond, shaft 30 feet, tunnel 30 feet, which will tap the ledge at a depth of 110 feet; the Lion, Hunter, Champion, Cressus, Summit, Yellow Boy, Little Annie, Rembling Sailor, Modoc, the Meagher and Elko tunnels, and others too numerous to mention. The Oracle Mining company (incorporated), the shareholders principally Sacramento parties, own the following mines: The Governor Stanford, down 10 feet, with promising indications; the North America, an A No. 1 prospect, down 16 feet; the Orphan Boy and Oracle tunnel, on which assessment work only has been done; the Awful Hole tunnel, which has a fine prospect of striking the ledge within 20 feet. The Carrie mining company has a shaft 55 feet in depth, with 30 tons of ore on the dump and 300 more in sight; shows a well-defined, true fissure vein, four feet wide, of No. 1 free milling ore, averaging the entire width of the ledge \$150 in silver per ton. The ore in all of the above mentioned ledges is very similar; that in the Black Diamond, Chloride and other locations on Chloride hill being the richest, but mines in other portions of the camp make up in quantity what they lack in quality. Fabulous assays have been obtained from this district, running all the way from \$100 to over \$20,000 per ton in silver alone.

The Severe Winter.

The severity of the last winter, which is unparalleled in "the memory of the oldest inhabitant," has been a severe blow to the stockmen, many of them having lost one-half of their bands, and mining operations have been almost at a stand-still for the past month, owing to the scarcity of mining supplies. While snow is still to be found in any quantities in the high ranges, the valleys are warm and dry. The contrast between Bull Run or Cornucopia and the beautiful valleys is marked in the extreme. After being snow-bound in the hills for four months, on the enforced diet of bread and bacon straight, your correspondent had the pleasure of spinning through the valley of the Owyhee a day or two since, and of feasting upon dishes that an epicure might envy. The bill of fare comprised sand-hill crane, wild goose—so fresh from sunnier climes than this, that rice was found in its crop—canvas-back, prairie-chicken, snipe, curlew, salmon, and last, but not least, a pot-pie of the famous reed bird of the Carolinas.

The next 30 days will doubtless bring many changes to Cornucopia and her denizens. The spring rush will commence, mines will change hands, roads will be opened, mail and supplies will once more arrive on time, and the threadbare joke of the captioned Cornucopians concerning "plenty in the horn," will have lost its significance.

CHERRY CREEK.—We are in receipt of a letter from one of the heaviest owners in the Geneva and Tea-cup mines at Cherry creek, in which most encouraging accounts are given of the appearance of things there. One car load of selected ore from the Geneva went \$1,368.50 per ton, and netted \$1,096.50 after all expenses had been paid. The vein from which this ore was taken, is said to be at the present time from six to thirty-six inches in width. The lower grade ore will mill \$400 and \$500, and shows a large body. We have no doubt that, under energetic management, Cherry creek will "come out strong" this summer. All hope so, at least.—*White Pine News*.

The Washoe Coal Mine.

Croppings of coal have been found in several localities in this section of the State, since the discovery of the Comstock lode, and some prospecting has been done in two or three places, but no great amount of work has ever been done on any vein in this vicinity. The place where most prospecting has been done is on a deposit in El Dorado cañon, about 11 miles above Dayton, Lyon county. Here, about 10 years ago, a shaft was sunk to the depth of 90 feet, and two veins of coal, from five to seven feet thick, were cut. This coal, though not what can be called first-class, burns very well and freely, but, being mixed with a considerable amount of shale, slate and other extraneous matter, it leaves a great quantity of ashes. The company who formerly owned this mine took out a good deal of pretty fair coal. They at one time established a coal-yard in this city, and had their coal on sale here. The Pioneer mill, Silver City, was once run for about a fortnight on the coal. The company, however, were unfortunate; a fire destroyed their coal-yard and dump in this city; the only hoisting machinery they had at their mine was a horse-whim; water came in on them, and, finally, they got into a wrangle among themselves, and the works were shut down. The mine is at present owned by the Nevada Coal Company, composed of citizens of this place, who will proceed at once to open it in good shape. They have purchased first-class pumping and hoisting machinery, which they will at once proceed to erect, when they will pump out the mine and open it in good shape, under the supervision of an experienced coal-miner. There is at the present a good wagon road from Dayton all the way to the mine, and, in case it shall turn out as well as is anticipated, a narrow-gauge railroad will be built. It is somewhat strange, but at the distance of two or three miles up from the mouth of El Dorado cañon, a region of sandstone, slate and other sedimentary rocks sets in, and this extends for some miles in all directions. This being the case, it is not unreasonable to hope for the development of a good and extensive coal mine near where the company have commenced operations; at all events, they will expend sufficient money to thoroughly prospect their ground, and will make the first really thorough and workmanlike explorations that have ever been made on any coal mine in this part of Nevada.—*Enterprise*.

Mines of Western Nevada.

The immense mineral wealth of Western Nevada is not yet fully appreciated or understood. The prevalent idea hitherto has been that the Comstock was the only mine of value in this part of the State, but recent explorations and discoveries prove beyond a doubt that all along the eastern base of the Sierra Nevada range are countless lodes or deposits of rich silver ores—extending for many miles both north and south of Reno, all of which will in time contribute to increase the wealth and business of this part of the State. Many of the oldest and best miners in the country, who have been off to new and distant excitements, are returning to prospect in what is generally called the Comstock range, believing it better than more distant fields of mining enterprise. Recently locations have been made near Silver City by old Virginia prospectors of the early days of Washoe, who have been absent for many years, and after having followed up all the excitement, been the pioneers of every new camp in Eastern Nevada, Idaho, Utah and Arizona, now return with the faith that here is the surest and safest part of the world in which to strike it rich. What is true of Virginia, is true of Aurora, Silver Mountain, Peavine and others, all having been abandoned years ago, for more distant and uncertain mining operations, and all now reviving and giving fair promise of great richness, and permanent and lasting prosperity. From all these camps mentioned, as well as those of Benton, Columbus, Lone Pine and Cerro Gordo, comes the cheering news of continuous and increasing prosperity and success in mining enterprises, the great and leading industry of the Pacific States.—*State Journal*.

STICKEN MINES.—The following appears in the *Colonist* as the latest from Cassiar: Sticken river opened on the 24th of April, when all the ice had given out. Twenty-five or thirty canoes started at once from Fort Wrangel for Buck's Bar. Gerke & Co. loaded their goods from the Otter into Moore's barge, and many canoes were on the point of starting. Messrs. Porter and McIntosh left the diggings on the 15th of April. There were then some 200 men in the diggings, and twenty-five or thirty companies were at work. The ground was still frozen, so were the creeks. The snow was two feet deep. One of Captain Moore's sons and a hired man were at work on Dease creek. They thawed the ground and washed it in a rocker, yet made from four to ten ounces a day! Rath Brothers had just got into the diggings. Nelson & Co. were making from \$30 to \$35 a day, thawing ground and washing it. Other companies were doing as well. Some of the boys were getting out sluice-lumber. One company had got sluices set. A new creek, called Delerrie, emptying into Thibert's creek, had been discovered. A prospect of four hits to the pan was reported and occasioned some excitement. Only three men were at work on the trail, which was blocked with fallen timber.

DEWEY & CO.,

American & Foreign Patent Agents,

OFFICE, 28 MONTGOMERY STREET, S. F.

The best, speediest, and surest method for you to obtain patents, file caveats, or transact any other important business with the Patent Office at Washington, or with foreign countries, is through the agency of DEWEY & CO., PUBLISHERS OF THE MINING AND SCIENTIFIC PRESS, SAN FRANCISCO, an able, responsible, and long-established firm, and the principal agents on this side of the continent. They refer to the thousands of inventors who have patronized them, and to all prominent business men of the Pacific Coast, who are more or less familiar with their reputation as straightforward journalists and patent solicitors and counsellors. We not only more readily apprehend the points and secure much more fully and quickly the patents for our home inventors, but with the influence of our carefully read and extensively circulated journals, we are enabled to illustrate the intrinsic merits of good patents, and secure a due reward to the inventor, besides serving the public who are more ready to give a fair trial, and adopt a good thing, upon the recommendation of honest and intelligent publishers.

To Obtain a Patent,

A well-constructed model is generally first needed, if the invention can well be thus illustrated. It must not exceed 12 inches in length or height. When practicable, a smaller model is even more desirable. Paint or engrave the name of the article, and the name of the inventor, and his address upon it. Send the model (by express or other reliable conveyance), plainly addressed, to "DEWEY & CO., MINING AND SCIENTIFIC PRESS OFFICE, SAN FRANCISCO." At the same time, send a full description, embodying all the ideas and claims of the inventor respecting the improvement describing the various parts and their operations.

Also send \$15 currency, amount of first fee of the Government. The case will be placed on our regular file, the drawings executed, and the documents made up, and soon sent to the inventor for signing.

As soon as signed and returned to us with the fees then due us, it will be sent straightway to the Patent Office at Washington.

When the invention consists of a new article of manufacture, a medicine, or a new composition, samples of the separated ingredients, sufficient to make the experiment (unless they are of a common and well-known character), and also of the manufactured article itself, must be furnished, with full description of the entire preparation.

For Processes, frequently no model or drawings are necessary. In such case, the applicant has only to send us an exact description, and what is desirable to claim.

For designs no models are necessary. Duplicate drawings are required, and the specifications and other papers should be made up with care and accuracy. In some instances for design patents two photographs, with the negative, answer well instead of drawings.

For further information, send a stamp for our illustrated circular, containing a digest of PATENT LAWS, 112 illustrated mechanical movements, and HINTS AND INSTRUCTIONS regarding the RIGHTS AND PRIVILEGES of inventors and patentees, which will be furnished post paid. Also a copy of NEW PATENT LAW of 1870.

GRAND INDUSTRIAL EXHIBITION,

To be held under the auspices of the

MECHANICS' INSTITUTE
OF SAN FRANCISCO, CALIFORNIA.

Opening on August 18th, 1874.

The Board of Managers herewith announce that a grand Industrial Fair will be held in the city of San Francisco for 30 days, opening on August 18, 1874.

In view of the increasing commercial and manufacturing importance of San Francisco, its contiguity to and close connection with the various countries bordering on the Pacific, the managers have constructed a Pavilion having a floor area of 150,000 feet, and have invited to it all who are disposed to come and exhibit. All exhibitors will be placed on the same footing. Motive power will be furnished free.

The building will be open day and evening, and every facility will be extended to exhibitors and visitors. Application for space must be made without delay to the Secretary of the Board of Managers, 27 Post street, San Francisco, and all inquiries will be answered and information extended promptly.

No space can be secured unless applied for before the 20th of July next. A. S. HALLIDIE, Pres.
J. H. OULVER, Sec'y.

A LECTURE TO GENTLEMEN

—BY—

BARLOW J. SMITH, M. D.,
Of the Allo-Hygieopathic Institute, 635 and 637 California street, San Francisco, California.

On the "Causes of Nervous Debility and Premature Decline." Also, "Twenty Years' Experience in Reform Medication," treating upon disease in its various forms, the Causes, Prevention and Cure, home treatment, etc. The two sent postpaid upon receipt of 25 cents. 18v28-3m

California Assay Office—J. A. Mars &
Wm. Irelan, Jr., Chemists and Assayers, Rooms 47 and 48 Merchants' Exchange, San Francisco. Analysis of Ores, Mineral Waters, Etc. 8v28-3m

(Continued from page 329.)

actual measurements would be received with incredulity. A column of vein-matter, thickly interspersed with mineral, averaging from four to seven feet broad, and not only cropping out for thousands of feet but actually standing in places from 10 to 30 feet above its enclosing walls, is not here a very remarkable sight. Several ledges have been recorded, measuring more than 50 feet in width, and in one instance, at least, a total breadth of 150 feet is attained.

3. The existence of mineral from the very surface: Thus far, prospecting has, on this account, been almost as easy for the mere novice as for the most experienced.

4. Accessibility of lodes for purposes of examination and rapid development, without the necessity of the usual delay and expense of sinking shafts: This last item is very much in favor of those who seek investments in the district before any considerable developments have been made. A few days' work with pick and gad, or half a dozen charges of blasting power, make feasible an examination more satisfactory in character than is possible in other districts after the expenditure of thousands. Parties who will make use of a modicum of mining sagacity will have no excuse, and deserve no pity, if they are bitten by "going it blind" on the San Juan silver lodes.

"Claim-Poor" Prospectors.

For this reason most of the prospectors who have penetrated to this section during the past three seasons, have done very little in the way of developing their property, preferring to secure a great number of claims which promise well, rather than thoroughly prove a few. They now find themselves "claim-poor," since they cannot possibly, on so many lodes, perform the minimum of labor required by law to avoid forfeiture. A penniless prospector, holding from 20 to 40 lode-claims, each requiring the expenditure of \$100 worth of labor each year, or otherwise becoming liable to be legally declared "abandoned," finds himself in possession of an elephant for which he has no fodder. He must sell a part of his property for whatever it will bring, or lose the whole. This is the condition of nine-tenths of the claim-holders in the San Juan, and probably nine-tenths of the best claims thus far located will change hands during the coming season. Shrewd operators, accompanied by experts, from the Pacific States and from the East, will be on hand as soon as the season is fairly opened, and will not be long in securing all the good "takes" that are offered.

The gold lodes of this region are not sufficiently numerous to merit particular mention.

The Little Giant

Is the only one yet worked, and is a remarkable lode. The quartz-ore from this mine is unlike any found in any other part of Colorado. It has some resemblance to a few of the Humboldt gold ores. The center of the vein, which has a total width of from two to three feet, is composed of crystallized quartz, varying from two to four or five inches in width. Outside this, on each side, is a layer or column of black material resembling hornblende, for which it was at first mistaken. It is soft, greenish-black in color, and varies in thickness from two to six inches. Outside this, on each side, are columns of gray quartz, uncrystallized, and containing more or less sulphurets of iron and copper. This is from four to ten inches thick, making the whole width of the pay-streak from twelve to thirty inches.

The white quartz in the center contains free gold and occasional crystals of sulphurets; the black streak—by some authorities pronounced *ripidolite*—contains free gold and is the richest portion of the vein. Assays from this have been made showing, as already stated, more than \$30,000 per ton. It is said that no assay has been made from this streak showing less than from \$900 to \$4,400 per ton.

The outer gray quartz contains little free gold but is rich in sulphurets of gold, requiring some process of calcination or roasting before it can be economically treated by amalgamation.

This vein crops out extensively on the face of a very steep mountain and is worked wholly by adits. Two tunnels on the lode have been started, the upper one being advanced fifty, and the lower one nearly two hundred feet. The pay streak has widened steadily since first opened.

The Remaining Gold Lodes

Have been but slightly tested. Two of them—the Central and Dexter, are located in the same mountain with the Little Giant, and both evidently intersect the latter at no great distance within the mountain. It is thought by some old miners that the three belong to one and the same mother vein. The Central points toward the Little Giant at an angle of about forty-five degrees, has a four feet crevice yielding from \$20 to \$50 per ton in gold and nearly as much in silver. The vein matter consists chiefly of a yellowish, uncrystallized quartz, free from refractory material. The Dexter has a seven feet crevice of similar material, and cuts the Little Giant nearly at right angles, apparently at about the same point as the Central.

It remains for mining enterprise to unearth the mineral coffers of this remarkable mountain.

The Sampson is another promising gold lode, showing a wide crevice of moderately rich yellow quartz. The gold is chiefly free, and the quartz easily reduced. Its permanent

value will be established by further development the coming season.

The Character of the Silver Lodes

Varies widely in different localities. The earlier localities were of argentiferous galena lodes. Perhaps a majority of all the discoveries yet made are of this class. Of the galena lodes, nine-tenths are of low grade, on the surface, showing all the way from a trace to fifty ounces to the ton. Not more than a score of these have been opened to any extent, but all thus tested show a rapid increase of richness with every increase of depth. From 20 ounces per ton, as a surface test they have shown from 120 to 250 ounces at a depth of from ten to thirty feet. A number of them show the miner's "gray copper" within a few feet of the surface, after which they rapidly increase in richness. The percentage of lead, as tested at the Denver mint, varies from 28 to 70 per cent.

A Second Group of Silver Lodes

Shows a much smaller per cent. of galena, and the vein matter consists of white quartz, heavy spar, galena, sulphurets of iron and copper and "gray copper" or antimonial sulphurets of silver. These lodes are richer from the start, surface samples assaying from 200 to 400 ounces. At a little depth this increases to 600 ounces or more, reaching in extreme instances as much as 3,000 ounces per ton. Sometimes the richness of these lodes is confined to a narrow streak not more than four or five inches wide at the surface, but steadily widening with every foot of increased depth. The balance of the vein matter, which is usually three or four feet wide—in many cases much wider—is not dead rock by any means, but is a low grade ore which, with better facilities, can be made profitable by concentration.

A Third Variety of Lodes,

None of which were brought into notice until the season of 1873, is by far the richest and most remarkable yet discovered. They contain no galena, and varying in width of crevice from two to five feet; are filled with a matrix of fluor-spar thickly epattered through from wall to wall with "gray copper" and black sulphurets of silver. Very little or no quartz appears in these veins: ruby and native silver, silver glance and horn silver are not uncommon, and the ore is remarkably rich from the very surface. Several of these lodes are claimed as having a two foot streak of nearly clear "gray copper." This statement must be taken with a grain of allowance.

The Ores.

Thus far very few lodes yield any considerable quantity of strictly milling ore. No doubt, as greater depths are reached, the proportion of this class of ore will materially increase. The better grade of galena ores can be readily smelted, and for this purpose the fluxing and other requisite materials are to be had in the vicinity. Hematite ores and fire clay have both been found within easy reach of all the principal mines yet discovered. Fluor-spar and pyrites of iron abound in certain localities, and in several instances extensive lodes of pure galena have been opened.

Another element which must eventually figure extensively in the separation and reduction of both gold and silver ores, is chloride of sodium. An inexhaustible supply of this material in any mining region would forever settle the vexed question of "refractory ores." Every chemist knows that cheap salt is equal to cheap hydrochloric acid, which is one of the solvents of gold itself.

This element exists in unlimited quantity not far from the new mining center. In fact, there is an actual mountain of salt to the westward of the Rio Dolores, called by the Spaniards who discovered it, *Sierra la Sal*.

Fire Clay and Coal.

Fire clay of good quality, and extensive beds of excellent coal have been found in the valleys of the southern San Juan slope. One party—an old miner at that—asserts that he has secured a vein of genuine anthracite, but this is to be doubted. It is probably the same as the Trinidad lignites, which might at first glance be mistaken for real anthracite.

Timber and Water

Are abundant for all practical mining purposes, and in many localities, unlimited water-power is of easy command.

As yet there is neither a stamp mill nor a smelter in the country. Several companies have projected smelting works to be erected the coming season, and the owners of the Little Giant have a fifteen-stamp mill principally on the ground and ready to set up.

A saw mill is nearly ready for operation at the foot of Baker's Park and others are to be erected.

Extensive placers are reported to have been discovered late last fall, along the Rio La Plata. How extensive and how rich they may prove the coming season will tell.

THE QUICKSILVER EXCITEMENT is extending into Santa Cruz and Santa Barbara counties on the south and Mendocino county on the north. The new mines in Santa Barbara county are about 18 miles northwest of Santa Barbara. The locality of the discoveries in Santa Cruz county is kept secret for the present.

THE Crown Point hoisting works will shut down on the 1st of June, and remain so for ten days, in order to put in the two new and powerful incline engines.

JAS. GLASCOB was fatally injured by a cave in the Empire mine, Grass Valley, May 16th.

PERSONAL.—Louis Janin, Jr., the well known mining expert, whose name is familiar at home and abroad for his theoretical and practical knowledge of his business, has returned from Japan, after a year's absence in that country, where he went under special engagement to examine the Japanese mines. He will remain in this city to practice his profession. His brother, Alexis Janin, still remains in Japan, where he has charge of extensive mining works belonging to the government.

TO BE INCORPORATED.—Emil Hendsch informs us that the Pacific Slate Quarry in Celestevae county, California, will be shut down until next August, when a company will be formed to carry on the work on a large scale.

THE new car house and machine shop at Donehue, to replace the buildings destroyed by fire a short time since, will be completed in a few weeks, and the machinery be put in operation.

THE placer claim of Lingle, in Peavine district, is turning out splendidly. He keeps four men employed, and is panning out over \$100 per day.

THE Well copper mine near Spencerville, Nevada county, has been started up again.

THE American quicksilver mine at Pine Flat has been purchased by capitalists.

CHINESE miners are migrating in numbers to Tuolumne county.

PATENTS & INVENTIONS.

A Weekly List of U. S. Patents Issued to Pacific Coast Inventors.

[FROM OFFICIAL REPORTS FOR THE MINING AND SCIENTIFIC PRESS, DEWEY & CO., PUBLISHERS AND U. S. AND FOREIGN PATENT AGENTS.]

By Special Dispatch, Dated Washington, D. C., May 19, 1874.

FOR WEEK ENDING May 5, 1874.

STATION SHIP FOR THEATERS.—Samuel H. Chapman, Sacramento, Cal.

MACHINE FOR MILLING METAL.—William Hawkins, San Francisco, Cal.

PACKAGE FOR AXLE GREASE.—John G. Hucks, San Francisco, Cal.

ICE MACHINE.—Samuel B. Martin, San Francisco, Cal.

CAR BRAKE.—James Herd, Jacksonville, Oregon.

CAN OPENER.—Albert H. Hall and Coiran I. Hall, Suisun City, Cal.

The patents are not ready for delivery by the Patent Office until some 14 days after the date of issue. NOTE.—Copies of U. S. and Foreign Patents furnished by Dewey & Co., in the shortest time possible (by telegraph or otherwise) at the lowest rate. All patent business for Pacific Coast inventors transacted with perfect security and in the shortest time possible.

The Mining & Scientific Press.

Started in 1859, is one of the oldest weekly journals now published in San Francisco. It has been conducted by its present proprietors for ten years, during which period it has been repeatedly enlarged and constantly improved. The active and steadfast efforts of its publishers have gained for its conduct an amount of practical experience greater than any other publishers have accumulated on this coast, of a weekly journal.

The sum paid by you for the best editorial talent obtainable for our special class journal; for engravings, for interesting news and correspondence, and for printing a large-sized, handsome sheet, is unequalled by that of any other American weekly west of the Mississippi. As a PRACTICAL MINING JOURNAL it has no rival on this Continent.

It is the only MECHANICAL, and the only SCIENTIFIC journal of the Pacific States.

Every Miner, Assayer, Millman, and Metallurgist in the United States should take it.

Every Pacific Coast Mechanic, Engineer, Inventor, Manufacturer, Professional Man, and Progressive and Industrial Student should patronize its columns of fresh and valuable information.

Every Mining Engineer, Superintendent, Metallurgist, Mine Owner, and Mine Worker in the world should profit by its illustrations and descriptions of New Machinery, Processes, Discoveries and Record of Mining Events.

Every intelligent thinker in the land, in high or humble situation, who would avoid literary trash for genuine information, should SUBSCRIBE AT ONCE.

DEWEY & CO.

The Pacific Rural Press,

NOW IN ITS FOURTH YEAR.

Is a Large, Handsome, Illustrated, Home Journal. Every Farmer, Gardener, Country Gentleman and Rural Homestead Owner should take it. Every Miner, Mechanic, Manufacturer and Professional Man and woman who contemplates rural life should read it.

It is worth its price for home reading. Send it abroad and extend a knowledge of our wonderful growing country. SUBSCRIPTION, \$4 a year. Sample copy free. Four copies (postpaid) 25 cts.

DEWEY & CO., Publishers.

No. 338 Montgomery St., S. F.

CHANGE OF PLACE.—It may be a convenience to miners, mill-men and others desiring labor of any description, including skilled mechanics, to learn that the employment office of A. Zeehandelaar, for the last six years Secretary and proprietor of the California Labor Exchange, has removed to 716 Montgomery street, corner Washington. We refer those in want of help, to advertisement in our columns.

DEWEY & CO.

American & Foreign Patent Agents,

OFFICE, 338 MONTGOMERY STREET, S. F.

PATENTS obtained promptly; Caveats filed expeditiously; Patent reissues taken out; Assignments made and recorded in legal form; Copies of Patents and Assignments procured; Examinations of Patents made here and at Washington; Examinations made of Assignments recorded in Washington; Examinations ordered and reported by Telegraph; Rejected cases taken up and Patents obtained; Interferences prosecuted; Opinions rendered regarding the validity of Patents and Assignments; every legitimate branch of Patent Agency Business promptly and thoroughly conducted.

Our intimate knowledge of the various inventions of this coast, and long practice in patent business, enable us to abundantly satisfy our patrons; and our success and business are constantly increasing.

The shrewdest and most experienced Inventors are found among our most steadfast friends and patrons, who fully appreciate our advantages in bringing valuable inventions to the notice of the public through the columns of our widely circulated, first-class journals—thereby facilitating their introduction, sale and popularity.

Foreign Patents.

In addition to American Patents, we secure with the assistance of co-operative agents, claims in all foreign countries which grant Patents, including Great Britain, France, Belgium, Prussia, Austria, Victoria, Peru, Russia, Spain, British India, Saxony, British Columbia, Canada, Norway, Sweden, Mexico, Victoria, Brazil, Bavaria, Holland, Denmark, Italy, Portugal, Cuba, Roman States, Wurtemberg, New Zealand, New South Wales, Queensland, Tasmania, Brazil, New Grenada, Chile, Argentine Republic, AND EVERY COUNTRY IN THE WORLD where Patents are obtainable.

No models are required in European countries, but the drawings and specifications should be prepared with thoroughness, by able persons who are familiar with the requirements and changes of foreign patent laws—agents who are reliable and permanently established.

Our schedule prices for obtaining foreign patents, in all cases, will always be as low, and in some instances lower, than those of any other responsible agency.

We can and do get foreign patents for inventors in the Pacific States from two to six months (according to the location of the country) sooner than any other agents.

Home Counsel.

Our long experience in obtaining patents for Inventors on this Coast has familiarized us with the character of most of the inventions already patented; hence we are frequently able to save our patrons the cost of a fruitless application by pointing them to the same thing already covered by a patent. We are always free to advise applicants of any knowledge we have of previous applications which will interfere with their obtaining a patent.

We invite the acquaintance of all parties connected with inventions and patent right business, believing that the mutual conference of legitimate business and professional men is mutual gain. Parties in doubt in regard to their rights as assignees of patents, or purchasers of patented articles, can often receive advice of importance to them from a short call at our office.

Remittance of money, made by individual inventors to the Government, sometimes miscarry, and it has repeatedly happened that applicants have not only lost their money, but their inventions also, from this cause and consequent delay. We hold ourselves responsible for all fees entrusted to our agency.

The principal portion of the patent business of this coast has been done, and is still being done, through our agency. We are familiar with, and have full records, of all former cases, and can more directly judge of the value and patentability of inventions discovered here than any other agents.

Situated so remote from the seat of government, delays are even more dangerous to the inventor of the Pacific Coast than to applicants in the Eastern States. Valuable patents may be lost by the extra time consumed in transmitting specifications from Eastern agencies back to this coast for the signature of the inventor.

Confidential.

We take great pains to preserve secrecy in all confidential matters, and applicants for patents can rest assured that their communications and business transactions will be held strictly confidential by us. Circulars free.

Engravings.

We have superior artists in our own office, and all facilities for producing fine and satisfactory illustrations of inventions and machinery, for newspaper, book, circular and other printed illustrations, and are always ready to assist patrons in bringing their valuable discoveries into practical and profitable use.

DEWEY & CO.,

United States and Foreign Patent Agents, publishers Mining and Scientific Press and the Pacific Rural Press, 338 Montgomery St., S. E. corner of California St., San Francisco.

GENERAL MERCHANDISE.

WEDNESDAY M., May 20, 1874.

A sale of 75,000 English Standard Wheat Bags was made this afternoon at 12 o'clock; also of 100,000 yards of Hessian, 4-in goods, to arrive at 10c. Coffee is steady. One or two downward movements in Olla are reported. Paints are rather duller. In Spices, Cloves have advanced 2½c, and Nutmegs have declined an equal amount. No change in the aspect of the Sugar trade.

PRICE...... \$

TO HYDRAULIC MINERS.

I warn Hydraulic Miners not to be misled by the advertisement of Mr. F. H. Fisher. Said Fisher has been beaten in every suit to which he has been a party (respecting Patent Rights on Hydraulic Machines), whether as plaintiff or defendant.

His patrons have already paid over Five Thousand Dollars for license to use machines purchased of the self styled

"Only Reliable Party in the Business Who Protects His Customers."

Fisher's Machine is worthless unless the discharge pipe is furnished with appliances, the patent for which is owned by Messrs. CRAIG, and which Fisher is engaged from making.

The Machine itself is also an infringement on another patent owned by the same parties.

All persons infringing on either of these patents

WILL BE PROMPTLY PROSECUTED.

I am sole LICENSEE to sell Machines manufactured under Craig's, Rice's, Macey's and Hoskin's patents.

I Guarantee Full Indemnity to all my Customers.

Machines of all sizes always on hand.

If you want a Machine that will give satisfaction, and do not want to pay for it twice over, buy an improved LITTLE GIANT.

CALIFORNIA

Quartz Crushing & Ore Sampling MILLS.

Nos. 413 & 415 Mission st., bet. First & Fremont, S. F.

Ours is the OLDEST, LARGEST and MOST EXTENSIVELY KNOWN establishment of this kind on the Coast.

Our mills are under the direct supervision of one of the most experienced Samplers and Millmen in the country, and we purpose carrying on the business upon a scale commensurate with the wants of the mining public.

We have the best facilities for Crushing, Sampling and Pulverizing all classes of Gold, Silver, Copper and Lead Ores and other minerals.

We also crush and pulverize all kinds of Marble, Fire-Clay, Bricks, Coke, Cement, etc., upon the shortest notice, for which we have special mills.

Reliable information furnished to miners and ore dealers concerning shipments, freights, prices, etc.

Prompt execution of all orders. Faithful attention to business entrusted to us.

Abundant storage room without extra charge.

Varney's Patent Amalgamator.

These Machines Stand Unrivaled.

For rapidly pulverizing and amalgamating ores, they have no equal. No effort has been, or will be spared to have them constructed in the most perfect manner and of the great number now in operation, not one has ever required repairs. The constant and increasing demand for them is sufficient evidence of their merits. They are constructed so as to apply steam directly into the pulp, or with steam bottoms, as desired.

This Amalgamator Operates as Follows.

The pan being filled, the motion of the miller forces the pulp to the center, where it is drawn down through the aperture and between the grinding surfaces. Thence it is thrown to the periphery into the quicksilver. The curved plates again draw it to the center, where it passes down, and to the circumference as before. Thus it is constantly passing a regular flow between the grinding surfaces and into the quicksilver, until the ore is reduced to an impalpable powder, and the metal amalgamated.

Setters made on the same principle excel all others. They bring the pulp so constantly and perfectly in contact with quicksilver, that the particles are rapidly and completely absorbed.

Mill-men are invited to examine these pans and settlers for themselves, at the office, 229 Fremont Street, San Francisco.

Morris' Settler and Amalgamator.

PATENTED MARCH 25, 1873.

An important improvement in milling. Cheap, light, efficient and durable. Gains Quicksilver on working tailings. Is discharged from the surface in the center instead of the side, by means of a Siphon which extends to near the center of the Settler. Heaviest casting weighs only 135 pounds. The sides and bottom of the Settler are made of wood, as also Mullers, placed vertically—the friction of which brightens the quicksilver. One of these machines is in daily operation at No. 616 Merchant street, (basement), San Francisco. Parties desiring information as to rights of use, purchase, etc., can address,

Manufacture and have constantly on hand

SPORTING,**MINING,****And BLASTING
POWDER,**OF SUPERIOR QUALITY, FRESH FROM THE
MILLS. It being constantly received and transported
into the interior, is delivered to the consumer within a
few days of the time of its manufacture, and is in every
way superior to any other Powder in Market.
We have been awarded successively**Three Gold Medals**By the MECHANICS' INSTITUTE and the STATE AG-
RICULTURAL SOCIETY for the superiority of our
products over all others.**HERCULES POWDER.**We wish to call the attention of miners and others of
our readers to a few points of superiority of the HER-
CULES POWDER over all other strong explosives.First—Its strength is greater than that of any other in
use. The materials of which it consists are com-
pounded upon strictly scientific principles, and not a
simple neutral absorbent employed that will hold a
quantity of nitro-glycerine. It is the opinion of the
best chemists to whom the matter has been submitted,
that no mixture has been employed that so thoroughly
promotes the whole tremendous force of the explosion
employed, and at the same time neutralizes the offensive
gases caused by the explosion. With this Powder one
half the time is saved that is lost by using any other
strong powder, before you can resume work after a
blast.Second—UNIFORMITY.—The materials of the mix-
ture are chemically prepared, and therefore greater uni-
formity can always be depended upon and the best re-
sults attained. This is a great advantage over any that
varies in its strength, as those must which are mixed
with any natural earth.Third—SAFETY.—So perfect is this mixture that no
accident can happen with it from premature or accident-
al explosion, if persons will half follow the rules laid
down for its use. No powder has ever been invented
where so few accidents have happened with it in pro-
portion to the quantities which have been used.Fourth—CARTRIDGES.—It is well known that nitro-
lycerine has a tendency to decompose by volatilization.
These are the "fumes" that are smelled on going into a
close warm drift or room where nitro-glycerine powders
are stored. To prevent the escape of these "fumes" an
air-tight hermetically sealed cartridge is employed, and
is effective in it that some cartridges filled with Her-
cules were exposed to a blazing California sun for six
months last summer, with no perceptible loss of
strength. This is a great advantage over the open por-
ous paper usually used for cartridges.Fifth—ECONOMY.—We believe that any miner who
will take the trouble to investigate the matter, will sat-
isfy himself that full fifteen per cent. is saved by using
the Hercules over any other strong powder manufac-
tured.QUERY—IS THIS WORTH SAYING? WE SHOULD
HINK SO. TRY IT.Sold by the CALIFORNIA POWDER WORKS, 314
California Street, San Francisco, Cal. Also, all grades
of Black Powder, Fuse, Shot, Caps, etc.

THE ONE-PLUNGER JIG,Delivered on R. R. Car at Denver, Col.,
or St. Louis, Mo.,Separates in one and the same operation—1. galena
and sulphide of silver; 2. pyrites or blende; 3. tailings,
containing no valuable parts; or, 1. gold; 2. pyrites; 3.
tailings (quartz, etc.) containing no valuable parts; or,
1. copper; 2. tailings, containing no valuable parts.
The One-Plunger Jig can be combined with existing
stamp-mills with highly important advantages, as after
amalgamation it will recover completely all fine meta
and all base ores and all mercury out of tailings. It
concentrates all fine metal ores to such cleanliness that
low grade ores can be shipped after concentration, as
first-class ores. Its feed and discharge are automatic.
Its construction offers better guarantee against loss and
repair than any other apparatus in use. For particu-
lar, apply to the inventor,

SAN FRANCISCO, SATURDAY, MAY 30, 1874.

VOLUME XXVIII
Number 22.

The Clay Street Railroad.

In answer to numerous enquiries about the Clay Street Hill Railroad, we would refer our readers to our issue of the 27th September, 1873, for a general description of this railroad, and add the following which has been forwarded to us by the patentee, Mr. A. S. Hallidie. The road was opened for business the 1st of August 1873. An interruption of three weeks followed to enable the tube to be extended one additional block (480 feet.) It has been running without interruption since that time, and travel on it has steadily increased. The length of the steel wire rope is 7,000 feet; its diameter, 15-16 inch, and is driven by a horizontal steam engine 12x24 inch running under 70 lbs. boiler pressure. The two patent grip pulleys through which the power is transmitted to the rope, are eight feet diameter each. The rope travels about four miles per hour. Distance between termini, 3,300 feet. Vertical ascent is 307 feet. There are five cars each with a dummy in constant use, running to the summit of the hill and starting every six minutes. The weight of each car and dummy is 4,500 lbs. The steel rope has now been running 10 months—the first two months 10 hours per day; the last eight months 14½ hours per day. It does not show much wear, and will probably last two years.

We have been able to obtain the following data covering a period of 90 days from 1st of July last:

Total number of passengers carried, 90 days.....	204,214
Distance traveled by the cars—miles.....	12,944
Total vertical ascent by the cars—miles.....	632
Average number of passengers per car per trip.....	19.72
Coal consumed.....	51
Coal consumed to each passenger carried, lbs.....	50-100
Total weight carried up grade—tons.....	33,516
Total weight carried down grade—tons.....	28,404
Greatest number of passengers on up line at one time.....	150
Number of passengers on down line, same time.....	10
Number of tons moved one mile.....	32,814.4
Coal consumed in moving one ton one mile, lbs.....	3.48
Average number of passengers carried per day.....	2,268
Miles traveled by the rope.....	5,148
Value of coal consumed per trip—cents.....	7
Total expense per car per trip—cents.....	74

From the foregoing this reader will be able to draw his own conclusions. The average number of passengers carried per day is now 3,000, and the expenses are somewhat less. We have watched from time to time the workings of this peculiar street railroad, and after ten months of steady working and through the test of a very severe winter, we feel in every way assured of its success, mechanically and financially.

At present the road terminates at the top of the hill. It is proposed by this company to extend it from the present terminus at Jones street, to the valley at Van Ness avenue. The economy of its workings compared to the ordinary horse railroad is so remarkable, that we believe if adopted on comparatively level roads, it would entirely exclude horse propulsion. If the line is extended to Van Ness avenue, the trip from Kearny street will be made in about 12 minutes, and the business of the line nearly doubled with but little additional outlay.

TRANSIT OF VENUS.—The "Swatara," which is to carry the scientific party to the south Pacific to witness the transit of Venus, December 18th, is in readiness to depart. The ship will leave the navy yard with two hundred persons on board. The company is to be divided into five parties, to be landed at Croset's Island, Hergnelan, or Desolation Island, Hobart Town, in Tasmania, (formerly Van Dieman's Land), New Zealand and Chatham Islands. Here the "Swatara" is to remain until after the observation. The vessel has stores for an eighteen months' voyage. The instruments are being tested in Washington, and are mostly new and very elaborate.

THE Iowa, an old location, lying south of the Utah mine, on the Comstock, has been idle long time, until a few days ago, when the owners, believing it to possess real merit, commenced sinking a new shaft, the superintendence of which has been placed under the able management of Samuel Owens, present superintendent of the Utah.

Hinkle's Hydraulic Hoist.

We witnessed this week the operation of a new hydraulic hoist for operating elevators in buildings, an invention recently patented through the agency connected with this office, by Philip Hinkle, of this city. The only one as yet put up in San Francisco has been placed in the old Academy of Music Building, on Pine street, which has recently been renovated and fitted up with offices. The elevator in this building brings the offices in the upper stories in close communication with the street. It is neatly fitted up and runs very smoothly, being under perfect control.

This operating mechanism is in the basement, immediately under the elevator itself, which runs between the usual guide timbers. A large pulley of peculiar construction is attached to the driving shaft, and the wire rope hoisting the elevator revolves around this pulley. A

two-thirds the length of the cylinder with a light load, while with a heavy one it travels the whole length.

Without this method of regulating the water supply, the same quantity of water would have to be used in all cases; and the operator states that in only one case in 20 is it necessary to throw the lever so as to raise a heavy load. For stores, the inventor claims to be able to save fully one-half the water by using it over again under the pressure of compressed air, compressed by the descent of the elevator.

Another arrangement perfected by Mr. Hinkle, and applied to the elevator in Pine street, is an air-brake, to cause the cage to stop without any jar. Two small cylinders are placed on the floor of the building, and when the cage comes down it automatically compresses the air in these cylinders, and is stopped gradually, without any concussion, always stopping at the same level. The safety apparatus is also of peculiar construction, being arranged so that if

THE BURLEIGH ROCK DRILL.

cylinder 10 feet, 9 inches long, and 16-inch bore, is placed in front of this shaft, and the chains revolving the shaft are fastened to this end of the piston. When the water is admitted to the cylinder it forces the piston out slowly, which unwinds the chains on the shaft, thus winding up the wire rope in the large pulley, which raises the elevator. The pulley has grooves cut in its face on which the wire rope fits as the pulley revolves. The wire rope passes over a five-foot pulley in the loft. The lower pulley is of peculiar construction. It is so arranged that on the single wheel are two pulleys, one of which is five feet in diameter, and the other seven feet, six inches. When it is desired to raise a heavy load, a lever in the elevator is moved, and when the water is turned on, the wire rope winds on the small pulley, so more turns are needed to raise the load. This being the case the piston is forced nearly to the end of the cylinder. When a light load is to be raised the lever is thrown back, which turns the wire rope on to the large pulley so that the piston only has to run two-thirds of the length of the cylinder to raise the elevator to the top of the building. By means of this peculiar pulley the inventor is enabled to save all gearing for raising different sized loads, thus lessening friction. Of course one-third less water is used in raising a light load than is used in raising a heavy one, as the piston only travels

the rope breaks, an iron bar on each side takes a grip, like that of a monkey-wrench, except that it has four jaws, instead of two. There are two doors in each of the four stories, and these doors run on rollers overhead, so that when the cage gets in the proper position the door is unlocked and opened. As soon as the cage leaves the station, the doors are closed automatically and locked at the same time. This arrangement is very safe, as no one can open the door from the inside without a key. The wire-rope used was made by A. S. Hallidie, a California manufacturer, and is a flexible, spring-steel rope, three-quarters of an inch in diameter, the breaking strain being 15 tons. The elevator runs up to the fourth story in the space of half a minute—a height of 52 feet. A bell is placed in the cage, which is rung by electricity, by pressing on a knob at any of the stations.

At the American quicksilver mine, Napa county, they are erecting a steam stamp mill for crushing cinnabar ore. They propose to crush the ore and mix it thoroughly with lime at the same time, so as to have it prepared for the furnaces. We understand that they are not to make adobes, as is usual, but will reduce it to a fine mass, mixed with lime. Quicksilver miners will watch with interest the result of these experiments.

The Burleigh Mining Drill.

This Burleigh drill, now being introduced largely in the mines on this coast, is applicable for tunnelling, mining, quarrying, open-cutting, shefting, submarine drilling, and, in fact, all forms of rock work. The machinery consists of the Burleigh drill and various forms of carriages or holders upon which the drills are mounted, for convenient application to the different requirements of rock-drilling and removal in its numerous phases. In tunnelling, this machinery is peculiarly advantageous. By its use great works become easy, that would hardly be undertaken with the old appliances of hand-labor; besides the great saving made in the labor of construction, the great saving of time accomplished by its use secures a great saving of interest on the cost of such works.

An experience of five years has enabled the manufacturers to produce very perfect appliances for the adaption of their machinery to this class of work.

The drill shown on this page is called the "mining drill," mounted on a mining carriage, which is used to great advantage in edits or drifts from 4-5 to 8-10 feet. It is the style of drill now in use in many mines in California and Nevada.

It consists of an upright column with a screw clamp nut for holding and raising and lowering the drill, the whole being mounted on a platform, which slides by means of a crank across the carriage, so as to adjust the drill to any position on the heading. It is secured in position by the jack-screw in the top of the column and arranged so as to be easily moved to permit blasting.

This "mining drill" bores from 1¼ to 2-inch holes and feeds 26 inches without change of drill points. Extreme length, 4 feet 7 inches; extreme size on cross section, 13-9½ inches. This drill weighs 475 pounds and requires 2½ horse-power to run it.

Tintic Mines of Utah.

We clip the following from an editorial in the Salt Lake Tribune of the 21st instant:

"The Shoebridge, Tintic and Wyoming mills are running successfully and turning out more bullion than at any previous time. The Germania smelter is approaching completion and will be producing copper matte within one month, if no unlooked-for delay occurs. Six hundred feet of the Gold Hill mine has recently changed hands, and the mine is now owned by the Tintic M. & M. Co. of San Francisco and the Otsego Silver Mining Co. of New York. This former has sight hundred and the latter four hundred feet. This mine averages from ten to twenty four feet in width of ledge, and the ore is being worked by wet process and without being assorted, at the Tintic mill. The fortunate owners claim for this mine the largest exhibit of high grade and free milling ore of any silver bearing lode in the Territory. The Diamond copper mine is being worked under the Superintendency of Col. Saxe, and is yielding a limited quantity of excellent ore. The mines are being quietly worked and each stage carries away the evidence of prosperity in the shape of silver bars."

The Tintic M. & M. Co., the Germania and Diamond companies are San Francisco incorporations. The former has been shipping bullion for some time and the acquisition of such a mine as the Gold Hill is claimed to be, will doubtless add to the production. The company is not on the list of the Stock Board, and has levied no assessments. The Germania company propose reducing the ores from their mine as soon as their smelter shall be ready for operations.

The cinnabar deposits near Temescal, San Bernardino county, are said to be richer than was at first expected. It is somewhat refreshing to chronicle this fact, as when a "quicksilver ledge," as it is called, is first struck, the lucky owners generally conclude it is the richest thing ever found; so when we see an item stating that a deposit is richer than was at first expected, we marvel at it, and are satisfied that it must be very rich indeed.

CORRESPONDENCE.

The Panamint Silver Mines.

EDITORS PRESS:—So little being known, and so little said of the new silver mining district discovered in February, 1873, in the Telescope range of lofty mountains, by the writer and two others, warrant me in offering the following to the public:

The mines are located about the center of the range and immediately south of Telescope peak, computed nearly 12,000 feet high. The extent of the mines is composed in blue limestone formation about 15 miles long by six miles wide, and in some places is capped with a brown slaty rock, but the base is lime and marble. The belt crosses three deep cañons running east, emptying into Panamint valley; they all contain streams of living water running from 10 to 30 inches, besides numerous springs. The mountain sides are covered with a dense growth of piñon (nut pine), cedar and mountain mahogany, with a species of fir near the summits, often measuring five and six feet through. We have our connection with Los Angeles and the S. P. railroad at Indian Wells, 75 miles southwest, one of the stations of the Telegraph Stage Company, running from the end of the railroad tri-weekly to Independence. A wagon can at the present time come within four miles of the mines, and the new road under construction by Messrs. Tart, Burchett & Co., who have a large force at work in the cañon, will be completed in 30 or 40 days, there lacking only a little over a mile to complete it, when loaded teams with supplies and machinery can pull right into camp and deliver their loads.

The majority of the ore are called copper-silver glance, varying in richness from \$200 assay to an amount I would be afraid to state; recently, however, in several of the lodes, especially the Esperanza and Wyoming lodes, extraordinarily rich ore has been met in sinking and drifting, of black sulphurets of silver, easily cut with a knife and which admit of a fine polish, as well as yellow and green chlorides. A large number of locations have been made, many of which will prove worthless on being worked on, but sufficient has been done to establish the fact that one-half dozen of main permanent leads have been found in the camp, varying from three to 12 feet wide, besides a large number of very rich small veins or feeders, which, as a general thing, with one or two exceptions, contain the richest ore. The main lodes have well defined walls, and nature has done a great deal in prospecting numerous lodes here, by steep ravines cutting the lodes at right angles and developing in these ravines rich chimneys of ore at the depth in places of 500 and 600 feet from the summit of the hills where the lodes crop out.

Some work has been done since the opening of spring, viz: on the Esperanza, a 25-foot shaft; lode increased in size from 1 foot on surface to 3 feet in bottom, well defined ledge and fine ore, average assays, \$450; 15 tons of ore on dump at the Wonder of the World, a 50-foot shaft, with vein 7 feet wide and heavy body of metal, and a fine lot of ore on dump; the Wyoming, a tunnel in 125 feet and approaching a heavy body of rich ore, vein from 3 to 7 feet wide. The company are now forwarding several tons of \$500 ore to the Cerro Gordo reduction works for an experiment, but this ruinous and expensive mode will be discontinued, as it can be more profitably worked in the district, even by the old fashioned Patio process. The Stewart's Wonder claim, on the Wonder mine, has been shafted to the depth of 25 feet, developing a magnificent body of ore—both black metal and chlorides. This claim was purchased without a pick being struck in the ground, by Mr. E. P. Raines and associates, last December, for \$20,000. He has been East during the winter, forming a company to work the mine; and I am informed he is now in your city, preparing to come out here immediately, fully prepared with capital and a mill to proceed to business in a proper shape; without a doubt he has a very valuable property. The Panamint Mining Company, who own the Wonder mine, are leveling off the site for a small mill which will be erected soon. Mr. Tollman, Superintendent for a San José company, has sunk on the Venus mine 50 feet, opening a fine body of ore. He is in your city now for supplies, and for the purpose of procuring reduction works. The majority of the claim owners and miners in the district are poor, and what is badly wanted in the district is a 10-stamp, custom mill. There are thousands and thousands of tons of rich ore in sight, which will pay \$100 per ton without election, and the miners could well afford to pay \$40 or \$50 for working and leave them a handsome profit besides. This district is well worthy the inspection of parties with capital, with an eye to this investment or to look at the mines. The miners, however, are getting tired of waiting, and are about to help themselves by erecting the old fashioned mule arrastras, and extracting the silver by amalgamation with quicksilver, salt and solar heat, as they can easily select \$400 or \$500 ore—good enough.

Mr. J. N. Newlander, of your city, is prospecting his "Sunriser" mine. I have seen some very rich specimens from this mine of born and native silver. An Oroville company, by their Superintendent, Mr. Chapelle, are prospecting

a number of lodes; amongst which the Mountain View, ranks first, a very rich argenteriferous galena lode. Some galena has been found in the district but not sufficient work has been done to establish the fact whether extensive deposits exist or not; work is being pushed on some of them claims and the matter will soon be determined. Water is abundant in this district and an inexhaustible supply of fuel can be delivered at the mills for years at \$6 per cord. In my opinion the most comfortable way of reaching this district would be by way of Los Angeles, there obtaining a light spring covered wagon with supplies (as none can be secured here), and the trip can be made from Los Angeles in seven or eight days. We have a mail route established and soon will have a stage line to connect with the Telegraph Stage company's line to Indian Wells twice a week—time from San Francisco three days. The snow has all disappeared from the hills and spring is well advanced. With pleasant weather a mining population is steadily coming in here and before midsummer this will be a lively mining camp.

"KAYWATT."

The El Dorado Ditch Company.

The Mountain Democrat speaks as follows of this company: Much and growing interest is felt, not only by our own people but among outsiders, as to the probable certainty and time of ditch improvement and enlargement by the El Dorado Deep Gravel Water and Mining Company. The other day we were called upon by an old acquaintance from Dutch Flat, a pioneer resident of that place, a practical and experienced hydraulic miner, who on his own account and as a representative of others in Dutch Flat and surrounding portions of Placer and Nevada counties, was anxious to obtain some accurate information. It is well known that we have an immense extent of unworked deep gravel claims, which have been thoroughly tested and proved to be rich, which enterprising and experienced miners from the comparatively exhausted hydraulic mines of neighboring counties, stand ready and have ample means to take hold of and open in a systematic manner, the moment they can be assured that they will be supplied with water without having to wait a lifetime for it. We don't know why there should be any deception or concealment in this connection. We don't see why the public, who have such vital interests at stake, should not have full and reliable information on the subject. But such is the case, and we give our readers and friends the benefit of our most rational conjectures, which is the best at our command, the best we have to offer, and is to this effect: Superintendent Bishop came up from San Francisco last week, accompanied by an intelligent and wealthy Chinese contractor. These two have been up along the line of the ditch and to its source of supply, making examinations which indicate an intention to enlarge the ditch and prosecute the work in the manner most conducive to the general welfare, and the indications are that a contract has been or is about to be let. But we want our friends, to whom definite and reliable information would be highly important and valuable, to distinctly understand that we only give the above facts and conjectures for what each reader, on his own responsibility, may consider them worth. When furnished from proper sources with anything more definite and positive, we will promptly give the public the benefit of the same.

Bullion and Charcoal at Eureka.

The Sentinel of last week says: There has been a second furnace set in motion by the Richmond company since the date of our last report.

The charcoal receipts for the week ending last evening were: Eureka Consolidated, 17,000 bushels; Richmond, 13,000 bushels; Hoosac, 10,000 bushels, and Ruby 5,000 bushels; in all, 45,000 bushels. These figures show an improvement on the amount received last week of 2,000 bushels.

The bullion product for the same period was: Eureka Consolidated, from two furnaces, 196,000 pounds; Richmond one furnace seven, and one three days, 127,000 pounds; Hoosac, 120,000 pounds of crude bullion, run from K K ore, a fact which should speak largely in favor of that mine and its stock. These figures give a total of 443,000 pounds, which indicates an increase over last week's run of 114,525 pounds.

The shipments were: by the Consolidated, 130,000 pounds; Hoosac, 20,048 pounds, and Richmond 95,087 pounds of refined bullion; which makes in all 250,135 pounds, showing an increase over and above last week's shipments of 103,785 pounds.

There were dispatched to the bank of California during the week, per Wells, Fargo & Co., from the Newark Mill and Mining Company, 2,154½ ounces of silver bullion, valued at \$1,911.96.

ARIZONA PLACER MINES.—We were this morning shown, at the store of Levi Bashford, \$1,000 in placer gold from the Lynx creek mines. Mr. D. P. Foster, who attends to such matters in that establishment, assures us that a greater quantity of gold has been taken out of the mines in this locality the present year than during any one since 1869.—Arizona Miner.

MINERS are rushing to the Twenty-nine Palms district, San Bernardino county.

The Eureka Consolidated Mine.

From an article in the Eureka Sentinel, by J. D. Power, descriptive of the mines of the Eureka Consolidated Company, we condense some interesting facts. The writer visited the mines and went all through them; so he speaks from personal observation:

The underground works are a perfect maze. One meets at each successive step a perfect labyrinth of drifts, cross-cuts, stopes, raises and chambers. They run hither and thither, in every conceivable direction, so that they cut and intersect each other at regular intervals. In this manner the ground has been finely opened—a procedure which facilitates its being mined, seen and worked to the best advantage. The ground appears to be admirably worked and timbered, betraying care, attention, judgment and skill on the part of its foreman and his timbermen. In the future, when portions of the immense ore reserves that are now in sight become mined and hoisted to the surface, there will be ample scope given to these gentlemen to exhibit their skill and experience in timbering. This ground, too, above all others, needs to be well and securely timbered and fixed against any possible future contingencies. It is not possible to have the vacuum thus created all filled in with waste without the expenditure of more time, labor and money to do it with than it would cost to have it properly and thoroughly timbered. This course would insure safety and firmness, and also allow of there being further work done, with entire confidence, in portions of the property which are as yet unexplored. The revelations which it is our province to give currency to this week, will, we opine, convey no little amount of pleasurable astonishment to the minds of those who are now, or may in future happen to become, directly interested in the fortunes of this company. A dividend was paid to the shareholders of this mine on the 8th inst., and dividends are now promised continually.

The Financial Status

Of the company has undergone a change under the present management, for it now finds itself with a surplus of \$100,000 on hand over and above dividends, debts, dues and demands. This amount will likely enough be increased at the end of this month by an addition of \$50,000 more. The current expenses for the season, for labor, coal, ore, hauling, water, etc., will foot up \$60,000 per month. This amount will appear small in comparison with the bullion which three or four furnaces will produce for the same period.

Some improvements are projected in connection with the furnaces, which will consist of a smoke flue and smoke stack, similar to those of the Richmond, which will add to the comfort and health of the employees.

The Lawton Shaft

Is situated about midway between the base and apex of the eastern slope of Ruby hill. Going down the shaft we stopped at the car station at the third level, which is a large and roomy and well ventilated, as is every portion of the mine. It is very securely timbered and also well lighted by a couple of coal-oil lamps, placed in convenient niches in the walls, in the immediate vicinity of the shaft, from which a flood of light was thrown upon the orifice by which the main southern drift traverses the ore region longitudinally from the shaft to the southernmost point, a distance of 375 lineal feet, allowing for curves, breaks, raises and descents. It runs perfectly smooth and level to the south out or manway, which is distant from the shaft probably 150 feet. (All distances given, or to be given, are approximated.) At this point we descended 40 feet of the said manway and found ourselves literally surrounded by ore. Nothing else was to be seen above or below, to the right, to the left, in front or in rear of us, but solid galena, gray carbonates, rich black sulphurets, and the red oxide that are so generally diffused throughout Ruby hill. Intermixed with these ores is found a kind of light-brown or reddish rock, some of which is soft and friable, and some hard and flinty, which is usually very auriferous, being found to often carry as high as \$35 to \$75 per ton in gold. From said above point the ore body, which is here twelve feet thick, is penetrated by a drift about 150 feet in lineal extent, which shows the same quality of ore throughout its entire length to its southern face, where it opens out laterally into a kind of chamber, which shows well in ore, without exhibiting any signs that would indicate the nearness of the foot or hanging walls. From here we retraced our steps to a point about midway between the north and south ends of the aforesaid drift, or rather gallery, which we have been describing, and which, we forgot to state at the proper place, is 40 feet above the third level.

From this place we ascended to the upper or second gallery, which is distant from the lower one 70 feet, through a raise whose angle of inclination is probably 65° or 70°. This gallery extends north and south like the lower one. The lineal dimensions of this gallery approximate to those of the one we had left. There are only one or two chambers, if such they can be called, that have been stoped out laterally and perpendicularly some 18 or 20 feet each way, all through a superior quality of ore. We must not forget to mention that the raise or incline connection between the first and second galleries reveals some very fine ore its whole distance, proving most conclusively that the intervening space is a solid mass of ore of a thickness of not less than 18

feet from wall to wall. To proceed, we will shortly mention, to avoid repetitions, that the second gallery developments are in all respects similar to the one below, with this exception, however, that ore body is solid, heavier and apparently richer, too, than it appeared to be on the other gallery. There are also numerous cross-cuts run east and west through ore, thus proving the continued thickness of the ore vein, which, in this neighborhood, has an average thickness of at least 18 feet between walls. The pitch of the ore is northeast.

The Third Gallery

We reached by a raise also, whose pitch is about 35°. It is run like the preceding one through first-class ore, some 60 feet to the third gallery, which is not quite so fully opened up as the others are. Never outside of the Richmond mine have we ever beheld anything to equal the ore body developed in that portion of the ground that is being worked through the Lawton shaft. Our terms of praise can not be too high, and we are satisfied that we do not exaggerate when we place the amount of the ore exposed in this portion of the workings at 40,000 tons. From the third gallery a further raise of 70 feet has been made through ore equally as good as any found at a greater depth. The inclination of the raise or incline is about 60°. We visited some few other points to the north and south, and likewise examined an ore shaft which communicates with a point close to the shaft at the third level, through which the ore is conveyed to them, thus doing away with much labor and expense. There is a timber shute, too, close by, through which the heavy timbers used in the mine are hoisted by windlass power on rollers placed and designed by the foreman to facilitate their being hauled up from below. From this point we descended by a man way to the old workings on the

Fourth Level,

A distance of 80 feet, where there is still considerable ore exposed in a few places. Close to the shaft on this level we found a vertical vein, which has been sunk about 30 feet, or perhaps more. One side of it is in lime, while the other shows well in ore, thus proving the continued descent of the ore, though in far less quantity than above. From the shaft at the

Fifth Level

There is a prospecting drift run north 175 feet, west 150, and south 45 feet, in which no ore of any account has been, as yet brought to light. Having now examined all that was in any way worthy of notice, we ascended to the top, got fresh candles and again descended to the tunnel level which communicates with the Lawton shaft. From here we wended our underground way through the hill a distance of several hundred feet to the old Buckeye workings, and from thence through a raise of some length to the

First Level

Of the Windsail shaft. One hundred feet south of the shaft we came upon a really magnificent body of ore, fully fifteen feet thick in the stoped face of it that we saw, but how far up or down we cannot say. There are one or two other chambers from which ore is being extracted in large quantities, and which give promise of future heavy yields. The ore found at this side of the hill is, we have been told, much richer than that found on the opposite or Lawton side. The other levels that are worked through the Windsail shaft that we visited, are all of them looking admirably as far as ore is considered. Our own opinion is that the future will more than prove the excellence of this quarter of the company's large property, not more than a fourth of which has been developed.

The Series of Mines

Comprised in the property are, the Savage, Nugget, Champion, Buckeye, At Last, Mammoth, Sentinel, Eclipse, Tennyson, Kidd and Lupita. This last, which is situated on the eastern slope of the hill north of the Lawton shaft, is now being developed by the diamond drill, which has quite recently been set in motion, close to the southern and western boundaries of the Richmond. The bore will be continued a distance of 700 feet. The mines are employing 140 men and the furnace 60 more, in all 200. In conclusion, we must add that the wealth of ore which is now uncovered in the mines we have been glancing through is almost incomprehensible and must be seen to be fully appreciated. We will give the dimensions of the ore body which we explored in the ground opened by the Lawton shaft so that the skeptical portion of our readers, if any there should be, can draw their own deductions. It is uncovered 200 feet long on the course of the lode; average thickness, 18 feet, and greatest depth, or width, 160. Anybody that will take the trouble to cube these figures and divide the sum resulting from them by 14 the number of cubic feet in a ton, will learn that our aforesaid estimate of 40,000 tons was less than the quotient that will result from the above divisor.

STARTER UP.—The Krom concentrator, in Star District, started up this week on ore from the Sheba and De Soto mines, of that district. We understand that it is the intention of the owners of the Seminole ledge, located in this district, to test several tons of their ore by running it through the concentrator, and if it turns out as well as is expected they will immediately increase the working force and commence an extensive development of their mine. At present there is exposed in the Seminole tunnel over five feet of ledge, well charged with black sulphuret and galena ores, and we can see no reason why it should not pay.—Silver State.

SCIENTIFIC PROGRESS.

Electroplating.

At a session of the Physical Association, of Frankfurt, Dr. Otto Volger delivered an address on the history and progress of the art of depositing metals by galvanic action, of which the following is an abstract:

At an early date it was known that a current of galvanic electricity was able to decompose liquids, and that metals deposited from solutions of their salts by this means assumed fantastic shapes, which appeared so similar, at the first glance, to vegetable growth, that they were called galvanic trees, or metallic vegetation, although really consisting of crystals, and formed according to the laws of crystallization. Professor Bottger took especial delight in pronouncing this sort of vegetation with different metals.

The use of such metallic deposits for electroplating was discovered accidentally. In 1830, Mr. J. P. Wagner, of Frankfurt, and Professor Jacobi, of St. Petersburg, were endeavoring to employ electro-magnetism as a motive power, instead of steam. Jacobi employed a Daniell's battery, which is distinguished for its constant and regular action. It consists of an outer cup of copper, and an inner cell of unglazed porcelain which contains the zinc rod. The intermediate space is filled with a saturated solution of sulphate of copper. When the battery is working, this solution of blue vitriol is slowly decomposed, depositing metallic copper, which finally becomes injurious, and must be removed. Once when Jacobi was busied with removing such a deposit from his copper cup, he noticed that there were several layers of copper, each having the form of the sides of the copper vessel, and hence, concluding that the sheet of copper of which the vessel was made had split up into layers, he accused the man who made it of employing a poor quality of sheet copper. A closer investigation, however, showed him that these layers, or leaves, did not belong to the walls of the vessel, but to a new deposit of metal, which imitated, in a remarkably perfect manner, the shape of the surface of the walls. It occurred to Jacobi that this troublesome disadvantage could be turned to profit by using it for reproducing objects. In 1838, he communicated to the St. Petersburg Academy a description of his discovery of the use of galvanic electricity for reproducing objects in the arts.

Czar Nicholas requested a German chemist named Klein, who was then employed in the imperial printing office, to test the practicability of the discovery and to ascertain to what extent it was capable of development. The answer being a favorable one, he gave the discoverer the means of making his new art the common property of the whole world.

Electrotyping, or plating with copper, consists in merely making the object to be copied the negative element of a simple Daniell's battery. If the object is a conductor, metal for instance, and is to be only partially covered, the parts that are to remain uncovered are rendered non-conductors by coating with some non-conductor, as wax, stearin or varnish. If it is a non-conductor, its surface is rendered conducting by brushing it over with a thin film of the finest graphite or silver powder. Murray discovered that graphite works the best. The reaction consists in the separation of the sulphate of copper into sulphuric acid and oxide of copper, while the water is simultaneously separated into oxygen and hydrogen. The sulphuric acid liberated at the anode or positive pole, unites with the oxide of zinc, formed there by the oxygen given off from the decomposed water, to form sulphate of zinc, which goes into solution.

The hydrogen evolved at the opposite pole abstracts the oxygen from the oxide of copper, and forms water, while the copper is left in a metallic state. Hence it is really the hydrogen which causes the reduction of the oxide of copper to metallic copper, at the negative pole or cathode.

Up to the year 1840 this new art was only employed for making small copies, like coins and medals, and these often came out of the mold imperfect, or were broken in detaching the mold. At that time, however, Professor Bottger prepared handsome relief plates of copper, and also employed galvanism for depositing a metallic coating on other metals, as for instance, gilding silver, copper and brass. In the same year, a copper-plate engraver, named Kress, came to St. Petersburg, learned from Klein the galvanoplastic art, as Jacobi had named it, and became acquainted with the latter. Jacobi called his attention to the fact that he could in this way make perfect copies of his etched or engraved plates, thus multiplying the original plate so as to obtain a great number of the most excellent impressions; for it is well known that a plate soon loses its sharpness, and every impression is poorer than the preceding one. At this suggestion Kress took up the art, and by 1844 had brought it to great perfection in his business. In 1841 Professor Bottger had made a copy from one of Professor Felsing's copper plates, in Darmstadt (the *Ecco Homo*, after Guido Reni, 12½ inches by 9½ inches), which was so perfect that Felsing declared that proofs printed with it were identical with those from the original plate, and of equal value. These plates are still in existence, the one in Berlin Museum, the other at Frankfurt on the Maine.

Boiler Explosions.

The behavior of water is totally different from that of gunpowder; when a charge of powder is fired in a gun the entire energy stored previously in powder is exerted on the gun and the projectile. When a boiler explodes, a very considerable portion of the energy previously concentrated in the water is expended, not on the boiler, or building, but in converting more water into steam at atmospheric pressure, and it thus happens that although the destruction wrought by the explosion of a large boiler may be fearful, matters are never as bad as they would be but for the remarkable property possessed by water, of instantaneously utilizing its stored-up energy in the comparatively harmless way of flashing a portion of itself into low-pressure steam. All the latent energy in the boiler was not thus expended, we know. A portion was expended in doing work—very disastrous work, no doubt, but none the less real. And this brings us at once to the puzzle, or puzzles, to which we have referred. We hear of stones being flung long distances, while a flue was lifted high in the air and fell on the roof of the weaving shed. Let us take this flue as typical, and ask ourselves how it was raised? The obvious answer is "Oh, the steam carried it there." Precisely; how did the steam carry it there? When a projectile is discharged from a gun an enormous pressure is exerted on its base for a considerable portion of time; but what are we to think of the nature and mode of action of the force which lifts a flue out of its place after the containing shell has been rent to atoms, and sends it flying through the air? Literally, not more than a few pounds of steam could find access to the flue to do the work; its surface was too small. Taking the flue at 30 ft. long, and just allowing a strip of its surface 3 ft. wide as an effective basis for the action for the steam, we have only 90 ft. surface. A body of steam at 80 lbs. pressure and 1 ft. thick over this surface would weigh about 2 lbs. only. It is impossible to imagine a sufficient velocity imparted to this 2 lbs. of steam to enable it in any way to impinge on the flue and thus propel it through the air.

Nor shall we be helped if we say that the pressure beneath the flue was unbalanced the moment the shell burst, and this unbalanced pressure lifted it. The pressure must have operated for a considerable time after the flue started on its flight, otherwise no energy could have been stored in it to enable it to continue its ascent. To what then are we to look as the direct cause of the ruin which attends a boiler explosion? Where is the link between the energy stored in the water and the walls blown down at a distance, the scattered bricks of the seating and the flying boiler plates? We do not think it too much to say that these questions have never been answered, and that the effects developed are perhaps after all manifestations of the exertion of force by the aid of very minute quantities of matter, operating in a way which is not quite understood. The cause of a boiler explosion is one thing, the cause of the effects of an explosion is quite another. We hold now, as we have always held, that there is nothing occult about the reason why a steam generator bursts. Neither, perhaps, is there anything mysterious about the flying of plates and the loss of life, and the ruin of buildings; but it is quite certain that no solution yet put forward has proved capable of that accurate numerical demonstration which can alone insure its acceptance. That ruin ensues when a boiler bursts we know, but we do not know whether a flying brick flies because it has been subjected to intense pressure acting through a limited space for a short time, or whether it is carried on a blast of steam as a leaf is carried by the wind, or whether it is driven by energy transferred from a mass of water moving, and whose movement the luckless brick has checked. Nor is it quite certain—although, in deference to accepted opinion, we have spoken as though it were certain—that the first effort of energy set loose in the rent boiler is to convert more water into steam, and not to manifest itself in some other way which is apparently occult, but only so because very little is really known about the manifestations of energy, or the bond which exists between force and matter.—*Engineer*.

THE CHEMICAL CLASSIFICATION OF IRON.—M. Frémy, an eminent French chemist who has recently been studying further into the metallurgy of iron and steel, thinks that it would be of much more advantage to founders and metallurgists if commercial iron, which is still classed according to its physical properties, should be known with reference to its chemical characteristics, that is to say, in accordance with the very small quantities of carbon, sulphur, phosphorus, etc., which it may contain, and which chemical analysis would reveal. This chemical classification has for some time past been in use in Krupp's celebrated foundry where, in fact, nothing is left to chance. Chemists constantly analyze the crude materials and the fabricated products. The scientific and industrial element is intimately connected with the military. Artillery officers examine the manipulations and follow their every detail. Considerable sums are devoted to new experiments, made on the different alloys which may be suitable for cannon, and of each metal tried there is compiled a record which indicates its chemical composition, its advantages and defects. According to M. Frémy's investigations, it appears that the best metal for guns is neither iron nor steel, but some combination of both.—*Sci. American*.

MECHANICAL PROGRESS.

The Whims of Machinery.

There are, says the *Scientific American*, some curiosities about machines which seem unaccountable. Every user of a sewing machine knows that from some unknown reason the machine which yesterday performed its work so well, so almost enthusiastically, to-day refuses to do more than half its task, and does that half in a sorry, indifferent manner. So with many other machines. Even the steam engine is subject to these fits. Is there some occult bond of sympathy between the operator and his machine, by which the latter is influenced by the mental condition of the former? For it is certain that these differences cannot be due to atmospheric or other external influences. This matter is quite humorously and truthfully treated in the subjoined extract:

It is perfectly well known to experienced engineers that if a dozen different locomotive engines were made at the same time, of the same power, and for the same purpose, of like materials, in the same factory, each of those locomotive engines would come out with its own peculiar whims and ways, only ascertainable by experience. One engine will take a great deal of coal and water at once; another will not hear of such a thing, but will insist on being coaxed by spadesful and bucketful. One is disposed to start off when required at the top of his speed; another must have a little time to warm at his work and get well into it. These peculiarities are so accurately mastered by skillful drivers, that only particular men can persuade engines to do their best. It would seem as if some of these "excellent monsters" declared on being brought out of the stable, "If it's Smith who is to drive, I won't go. If it's my friend Stokes, I am agreeable to anything!" All locomotive engines are low spirited in damp and foggy weather. They have a great satisfaction in their work when the air is crisp and frosty. At such a time they are very cheerful and brisk, but they strongly object to haze and mists. These are points of character on which they are united. It is in their peculiarities and varieties of character that they are most remarkable.

The railway company who should consign all their locomotives to one uniform standard of treatment, without any allowance for varying shades of character and opinion, would soon fall as much behindhand in the world as those great governments are, and ever will be, who pursue the same course with the finer piece of work called man.

Paper-Hanging Machine.

R. H. Miner has invented and patented a machine for paper-hanging, which is described as follows: A box is made of tin, sufficiently long to receive a roll of paper, and of a depth and breadth sufficient to contain the paste-roller and the desired quantity of paste, the case being nearly square. The paste-roller revolves on pivots in the ends of the case. The paper, which is dropped into the case, rests on an inclined hinged flap, and bears on the paste-roller. Before the paper is placed in the case a metal rod is inserted in the center, to give the paper additional weight to keep it steady and in place. An adjustable head bears against the end of the roll of paper, to prevent longitudinal motion. The paste-roller revolves in the paste, the friction against the paper being sufficient to cause it to revolve when the paper is drawn out. A pressure roller, which may be covered with felt, receives the face side of the paper. The paper is placed in the case, and its end is hooked into the bent. In hanging, the machine is raised to near the ceiling by means of a handle, and pressed against the wall. The paper releases itself from the hooks, and, as the machine is brought down, the roller presses the paper to the wall. The machine is used for papering overhead, and for putting on strips or bordering in a similar manner. By this invention, the tedious operations of unrolling, cutting up the paper, and spreading the paste are obviated, and the result is a very great saving of time.

STOVE-PIPE THIMBLE.—Mr. Thomas D. Slauson, of Havana, N. Y., has invented an improved stove-pipe thimble, which merits attention. The object of the invention is to furnish an improved casing for conducting stove-pipes through wooden partitions, which is easily fastened in position, protects the lathing fully against any danger by fire, and leaves no communicating holes between the rooms, being fully covered by the plastering. It consists in a double casing, which is attached suitably to the wooden partition, being provided with bent up face piece and side perforations, through which the circulation of the air around the inner casing is kept up.

PERPETUAL MOTION.—Some years ago, says the *American Artisan*, the Patent Office was so beset with applications for patents on perpetual motion, that the Chief Examiner proposed the following reply which every applicant received:—*Dear Sir:* Bring your machine to Washington. It will be set in motion and placed in a closet secured by two locks, and I will give you one key, retaining the other myself. At the end of one year the closet will be opened, and if the machine is still in motion, your patent will be granted." This was the end of the correspondence.

Machines to Make People Honest.

Time was, when almost every stage driver in New York was known to abstract a greater or less share of all fares received, and his employer had no remedy and no sure means of detecting the rogue. But thanks to the ingenuity of the inventor, our Broadway Jehns have been transformed into honest men. They can't steal if they would. The patent money box in which the passenger drops his fare, relieves the driver from the duty of handling the money, and consequently none sticks to his fingers.

On the street railway cars, the pilfering conductor, although not rendered wholly honest, is considerably interfered with and his stealings reduced by means of the patent hell punch. He is required by the rules to punch a strip of paper for every fare received. The punch contains a hell, a dial numbering register, and a receptacle in which the punched hits of paper are received. The punch, paper and money are returned to the office by the conductor at the end of every trip. The dial pointer shows how many times the punch has been operated, and the count of holes in the paper, the punched bits within the punch, and also the money should all be found to agree. Any discrepancy is at once shown. But this device does not fully answer the purpose of detection, because the conductor may take fares and not work the punch, especially in a crowd, without being observed.

The money box plan is apparently the surest. There is a chance for some ingenious person to invent a portable box for conductors, which will be promotive of their integrity in crowded cars.

One of the latest dodges in this line comes to us from Constantinople. The driver or conductor of the car gives to every passenger a prize ticket bearing a number which is recorded on the company's books. A drawing takes place monthly, the company providing a certain number of prizes. We read of one passenger who lately drew a prize of \$100 in this way. The hope of drawing a prize makes the passenger careful to send in his tickets; and, if the money returns of the driver or conductor are not equal to the number of tickets returned, there is a showing of dishonesty, and the particular culprits may be detected by comparing the return tickets with the records of the tickets issued to the several conductors.—*Sci. American*.

FLOATS FOR SHIPS' BOATS.—The Marine Department of the London Board of Trade have been making experiments with the boats of coasters, and find that any old boat can be converted into an efficient lifeboat by using air casings outside. The Marine Department have, for this purpose, used air cylinders, which they have specially designed, fastened outside the boat by a netting; so that the boat can be used for an ordinary boat as long as wanted, and converted into a lifeboat when occasion requires it. The material used for these cylinders, and approved by the Marine Department, is a combination known as Clarkson's. It consists of a layer of cork, about a quarter of an inch thick, between two layers of strong canvas. One cubic foot of air space in these cylinders will support about 60 pounds. The cylinders of this material are the cheapest, most efficient, and most durable means yet invented for converting an old boat into a lifeboat. Mr. Clarkson has made the experimental cylinders on models furnished to him by the Marine Department, and, as we believe, prepared to supply any number demanded. Air cases, to place inside lifeboats, also made of this material, have been supplied to some of the mail steamers, and are much preferred by the Marine Department in cases of copper, iron, zinc or wood, as they are practically indestructible, are not affected by heat, and are very light.—*Nautical Magazine*.

COMPLETION OF AN IMMENSE SAFE.—Mr. Chubb, the well-known English manufacturer of safes, has recently completed, for the Government of Buenos Ayres, an iron safe of gigantic dimensions, designed to receive the title deeds and securities of the Department of Public Credit. It is a parallelopiped formed by plates of heavy iron, strongly riveted at the edges. Within this is a second box as strongly constructed as the first, and separated by an air space. In this interior safe the valuable property is placed. The interior filling is made with a composition whose character is at present a secret, but which appears to have a certain quantity of alum in it. The dimensions of the safe are: height, 11 feet six inches; length, 14 feet nine inches; depth, five feet. The plates are three-quarters of an inch in thickness, and at the corners the total thickness of the plates and braces is nearly five inches. Two doors, one and one-quarter inch thick, give access to the interior. They are made of steel and iron, and have compartments filled with non-conducting materials. The safety-locks are attached, containing each a charge of gunpowder capable of firing 14 projectiles in all directions. Each lock is of a different form. The safe, entire, weighed 15 tons. It was shipped in pieces, and is to be put together at its destination by a competent mechanic, who accompanied it for that purpose.—*Jour. of F. Ins.*

A new mitrailleuse is spoken of, which at 500 yards will distribute bullets one foot apart along a horizontal space of 22 feet. The 24 barrels are arranged in two circles, eight in the inner and sixteen in the outer, and 700 balls per minute can be discharged.

Mountain Company, on Quartz mountain, near Lower Rancheria. The ledge is well defined and the rock exhibits a fine array of free gold, and well charged with gold bearing sulphurates.

STILL IMPROVING.—*Dispatch*, May 23: Reports from the Amador quicksilver mine still continue to be more favorable as the work of development goes on. As an evidence of its increasing richness we are reliably informed that an offer of fifteen dollars per share was refused by one of the stockholders a few days ago, while only a few weeks ago a large number of shares were sold at one dollar each.

MORE QUICKSILVER.—Two or three additional quicksilver claims have recently been taken up within a few miles of the Amador mine, and are now being thoroughly prospected.

THE RIO DITCH.—Digging on the Amador canal is now about completed, and in the course of a couple of weeks the water will be turned in.

CALAVERAS COUNTY.

NEW MILL.—*Chronicle*, May 23: Preparations are being actively made for erecting a mill on the Zacateno mine at West Point. The lumber is upon the ground and everything being got in readiness. It is to be a ten-stamp battery.

QUARTZ DISCOVERIES.—Two additional quartz veins have been recently discovered at Mosquito Gulch. Fields & Co., and Rickman & Co., are the lucky parties. Work has been commenced on both ledges, which prospect very well.

GARLAND'S mill, at Mosquito, is still running on San Bruno and Dolly Varden rock.

COLUSA COUNTY.

FROM BEAR VALLEY.—*Cor. Independent*, May 23: The all-exciting topic here at present is quicksilver. Mr. Lovelace has struck as rich a lead as these hills have ever produced. A small seam of cinnabar, inlaid in some soft rock, led to the valuable discovery.

Mr. J. B. Turner and others have located a claim in the same vicinity, and found rich ore in paying quantities. H. M. Cromer, of Spring valley, has also struck it lucky.

It is a little amusing to see every morning the fortune seekers making for the hills in all kinds of style, in wagons, on horseback and on foot, bound to find a ledge before night. It is nothing unusual to find a man's coat tail or the leg of his pants hanging on a juniper in the hills west of Bear valley.

EL DORADO COUNTY.

SPANISH FLAT MINING INTERESTS.—*Cor. Mountain Democrat*, May 23: A correspondent from Spanish Flat under date of May 17th writes: "It has been one of the richest mining camps of El Dorado county, and undoubtedly is destined to be one of the most productive quartz regions in the State. The Spanish Flat Hill, which is situated on the line of this belt of porphyry, has been and now is rich in placer mines, which extend to the very summit. In fact, every pan of dirt, it matters not from what part of the hill it be taken, shows a good prospect. But now the Spanish Flat Tunnel Company have commenced work in their tunnel, and ere long we may expect to hear of some rich developments. The same company is also running a hydraulic claim in one of the gulches running down from the hill and it is evident that they mean 'business'."

"There is also a company running a tunnel about one mile from this place. I understand that they have already struck a good lode, but are still pushing their tunnel ahead to develop others."

LOS ANGELES COUNTY.

NEW MINES.—*Cor. Herald*, May 19: Cahunga claim was discovered by Mr. Bell and owned by him, in company with Gov. Downey, Mr. Potts, Mr. Desmond and another party whose name we did not learn. The ledge is about a foot thick, and is well defined for a distance of thirteen hundred feet. It rises like a perpendicular wall to a height of eight or ten feet for a part of this distance. The rock is genuine quartz, gold bearing, with a small proportion of silver. Specimens from it have assayed nearly ten dollars to the ton, taking both metals together, and that from surface rock. One of our party (a forty-niner, by the way, whose opinion is worth something on almost any subject), says that it presents one of the best indications which he has ever seen. It is what miners term in their vernacular an A lead, the ledge being shaped something like the outlines of that letter—rather thin at the top and gradually attaining a greater thickness as it descends. There is evidence of a great mass of rock at this place, and if it should yield no more than ten dollars per ton throughout, as the specimens have assayed, the ledge will pay handsomely for developing. It will be quite easily worked lying as it does, so well exposed already. The ore can be conveyed to the bottom of the cañon by chutes, whence it is only a mile to the valley. Over this distance a road can be built without great difficulty or expense. There is abundance of wood and water in the cañon for all mining purposes such as would be required. From this place we retraced our steps part of the way, and going further up the cañon climbed another mountain, less lofty than the first, where we found another claim, Rough and Ready. This ledge is not so well defined, as the first, but can be traced to a considerable distance, where it again crops out further up the mountain. It is a quartz formation like the other, and bears about the same proportion of gold and silver. This claim is in the hands of the same company as the Cahunga, and was also discovered by Mr. Bell. The company will commence work on the two claims this week, and will push them to a speedy development.

They are all men of well known enterprise, and have invested sufficient means to give a thorough test of the ledges. They will soon find whether they have fortunes in them or not.

At the bottom of the cañon and near the head of the stream, is another ledge owned by Mr. Plummer. It is called the El Dorado claim. The rock is of dark bluish gray color, containing pure gold without any accompanying base metals. Specimens have assayed over ten dollars to the ton. Mr. Plummer intends to commence work upon his claim very soon. He also has two other leads, called respectively the Solita and the Elko; the former was the first which was discovered in the cañon, and took its name, being at the time *solita*—alone. There are a few other claims in the section, but we did not visit them.

MARIPOSA COUNTY.

RICH QUARTZ.—*Gazette*, May 22: A specimen of the quartz now being taken out of the Blue Vein by Mr. A. H. Brooks, the proprietor, weighs about forty-three pounds avoirdupois, and is estimated to contain about \$100, in free gold, besides abounding in very rich sulphurets.

HITE'S COVE.—One of a superior quality is being taken out of the mine of Hite & Co., some three or four hundred feet above the lower level. The miners say it is paying better than ever.

NAPA COUNTY.

QUARTZ MILL.—*Free Press*, May 22: Tuesday and Wednesday heavy machinery came up destined to the American quicksilver mine. A quartz mill of twenty-four stamps was among the rest. The mortars to this mill weighed 2,500 pounds each. The owners of the mines are having a furnace built, retorts erected, and everything done to get to running on the metal. The mine when developed promises to be a good one.

On Thursday last, Mr. Livermore, superintendent of the Redington quicksilver mine, was in town. He says the Redington is losing none of her reputation as an excellent mine, but on the contrary is increasing her yield and paying handsome dividends.

NEVADA COUNTY.

RICH STRIKE.—*Transcript*, May 16: A rich strike is noted in the Lone Star mine near Nevada city, owned by Murchie brothers. They have been running a tunnel for some time and struck the ledge on Friday, finding it two feet thick, with specks of gold all through it and a large amount of sulphurets.

MOORE'S FLAT.—*Union*, May 22: The mines at Moore's Flat are mostly idle on account of the difficulties about water. The miners there want their water for eight cents an inch and the owner of this ditch wants 12½ cents an inch for the water. The miners will not pay the price demanded, and the ditch owners will not sell for the price offered and so work is stopped. The miners have some hopes that a second ditch will reach the Flat, and that when it does water will be furnished at eight cents an inch. The North Bloomfield Gravel mining company is looked to for this second ditch. It is probable that the Bloomfield company will have very little water to sell, no matter how many canals it may construct, since their own extensive mines will use all that can be obtained. Meantime the ditch owner now supplying Moore's Flat with water will soon have ground open upon which he can use all his water. The miners are not masters of the situation, we think.

PLACER COUNTY.

RICH STRIKE.—*Argus*, May 23: On Monday afternoon last Superintendent Crossman, of the Bellevue mine, showed us a sample of very rich rock, which has just been struck in the 240-ft. level of the Bellevue shaft, and which will assay on an average \$1,000 per ton. The vein is about thirty inches in breadth.

THE ORLEANS MINE.—Noticing an item in last week's *Herald* setting forth the fact that "a rich strike had been made at the Orleans mine," we wended our way a few days ago in that direction to see for ourselves, and had our most sanguine expectations satisfied at the result. The Orleans gold quartz mine is situated about a mile and a half from Auburn. The new development is a vein fully six and a half feet wide, the rock from which pays over \$100 per ton for the last 20 ft. in the tunnel. This rock is crushed at the Pugh mill, near Ophir, and can be mined and milled at \$4 per ton, so that from this estimate can be seen the great income and value of such a claim.

MINING.—*Herald*, May 23: At the Crater Hill the stopes are turning out immense quantities of very high grade ore. About 50 men are now employed on this mine.

At the Bellevue, work is being pushed ahead rapidly and systematically. Six different shafts are being sunk in pairs, each pair about 100 ft. apart, which will be connected by drift at a depth of 200, or 250 ft., for the purpose of facilitating work on the stopes and affording ventilation. They are working as on three different mines. The object of this plan, we understand, is to make room for a sufficient force to take out ore enough to keep their mill, which they intend enlarging to 20 stamps, constantly running.

THE LINCOLN COAL MINE.—Fourteen men are now employed about the mine; but the number will be largely increased when the new shaft is finished, which will be in about two weeks.

PLUMAS COUNTY.

RICH QUARTZ.—*National*, May 16: Mr. A. C. Light, whose mine is on the mountain south of Indian valley, is again taking out some very rich rock. We are told that a few days ago he "made a run" with his "hand mortar," and

cleaned up over \$2,000. This gold is in small veins of quartz, and occasionally a "pocket" or rich spot is found which yields fabulously. Mr. Light has already ponded out some \$18,000.

SAN DIEGO COUNTY.

THE BLADEN DISTRICT.—*World*, May 16: From Doc Martin, who has just returned from Bladen, we learn that matters and things are progressing in that locality in a cheerful manner.

Arrangements are being made to commence operations at once on the Topsy Johnson mine and develop it as rapidly as labor and money possibly can. Mr. Martin says the health and spirits of everybody at Bladen are excellent.

SANTA BARBARA COUNTY.

NEW MINES.—*Index*, May 21: There are several mining experts and well known quicksilver capitalists in our paradise to-day. We interviewed several of them without solicitation, but from others learn that extensive deposits of cinnabar have been discovered in the Santa Ynez mountains, about ten miles from Santa Barbara.

SIERRA COUNTY.

OAK RANCH.—The prospectors, at Oak ranch, some two weeks since, commenced running a lower tunnel to tap the large bed of pay gravel, demonstrated to be under the flat. They are working three shifts, and running ahead in bedrock at the rate of 24 ft. in as many hours. This seems hardly to be credited, yet our information is from a reliable source. The tunnel is already in about 180 ft.

GOON PAY.—The York boys are finding excellent pay in their claim near Mt. Vernon ravine, in the head of Hungry Month. They brought down 11 ounces last week, the result of a few days' run without a full load of water.

CAVE.—An extensive cave occurred in the claims of R. H. Bliss, at Indian hill, on the 16th, covering up his "little giants" and tools.

SISKIYOU COUNTY.

HAMBURG BAR.—*Union*, May 23: We hear very encouraging reports from this camp, situated on the Klamath, a short distance below the mouth of Scott river. There are a large number of rich claims which will furnish occupation to a large number of miners for years.

JOHNSON & CO'S QUARTZ CLAIM.—Johnson & Co. have made one crushing of rock from their claim near Oro Fino, with very satisfactory results. The amount of rock crushed was twenty-five tons, and yielded from \$38 to \$40 to the ton.

Miners are about through working on Little Humburg. They have sluiced off more ground this year than ever before. In a little while they will be washing up.

TRINITY COUNTY.

W. D. & H. M. Co.—*Journal*, May 23: Last Thursday we visited the works of the Weaver-ville and Hydraulic mining company, on the Oregon Gulch and West Weaver Divide, and found everything progressing favorably. Two hundred and fifty men are employed on the ditch, which will probably be completed in two weeks. Not a foot of flume is required on the line of the ditch and only one tunnel—about 80 feet through a point of rock.

In the claim, flumes and undercurrents are being made and placed in position, and everything there will be in running order by the time water can be got through the entire length of the ditch. The reservoir, cut and tunnel have been completed and as soon as water can be had a hole will be sluiced out for the reservoir. Many persons from other and older and more advanced mining counties have visited this ditch and unanimously speak of it as the best and prettiest piece of ditch in the State.

TUOLUMNE COUNTY.

KINCAID FLAT MINE.—*Independent*, May 23: A rich spot of new ground has been struck in this mine, and we saw, at Kenfield's, a few days since, a nice pile of coarse gold, valued at \$1,200, which was "picked up," without the formality of a regular "wash down," at the place indicated. One solid piece weighed about two ounces.

THE BIGGEST CLEAN UP.—The Golden Gate ledge has proved a success under the skillful management of Slocum & Thomas. Under the circumstances, our home scientists have done remarkably well—raising the product of the mine, as heretofore worked by an expert, from 75 cts. per ton to \$40, from the same dump and identical quality of ore. During the last four days' run, previous to delivering the charge to Mr. Deland, the new Superintendent, 28 tons of rock were crushed, showing 56 ozs. of gold, or at the rate of \$39 per ton. Running time of mill under their supervision, 23 days—reducing during that time 160 tons, and shipping 172 ounces of gold—\$3,354.

Nevada.

WASHOE DISTRICT.

CONSOLIDATED VIRGINIA.—*Gold Hill News*, May 21: The station of the 1,500-ft. level is completed, and a drift east started to tap the east wall of the ledge, which is in a distance of 40 ft. Two additional cross-cuts have been run on the 1,400-ft. level, one near the shaft, and the other midway between the shaft and the north winze. The middle, or cross-cut No. 2, has penetrated the ore body a distance of 70 ft., and is still in rich ore. Cross-cut No. 3, near the shaft, is just fairly entering the ore vein, and shows it to be even richer at this point than at the north winze, 200 ft. further south. The ore breasts on the 1,300-ft. level continue to improve in the quality of the ore extracted almost daily. Daily yield of the mine, 300 tons of ore,

which is all the mills can crush. This yield of ore can be greatly increased, whenever the necessary mills can be obtained.

SIERRA NEVADA.—The heavy flow of water at the bottom of the new shaft continues without abatement. Putting in a large and strongly constructed tank for catching up the water is making rapid headway. The lumber for the new hoisting works is nearly all on the ground, also almost all the new machinery. As soon as the water company have completed the necessary flume for conducting the water to the ground, the hydraulic washing will be commenced. Daily yield, 60 tons of ore, keeping the mill steadily running.

CROWN POINT.—The ore body extending upward toward the 900-ft. level, continues to improve. The ore stops on the 1,400-ft. level are opening out splendidly, and that level is now promising to equal, if not excel in point of yield, either of the levels above. Daily yield, 550 tons of ore.

BELOHER.—Daily yield, 550 tons. The ore breasts throughout the entire mine are looking splendidly and promise a rich yield for many months to come.

UTAH.—Crosscutting the ledge at a point 200 ft. south from where the ledge was penetrated by the main west drift has been commenced, with some very favorable prospects of an ore development in that portion of the mine.

CHOLLAR POTOMI.—Daily yield 140 tons of ore, the assay value of which is \$30 per ton. The ore breasts are all looking well. The newly opened ore deposit in the old Balvidere section is quite spotted, the ore being quite poor in places and again quite good in others.

IMPERIAL-EMPIRE.—Cross-cutting the ledge to the eastward, on the 1,850-ft. level, is still vigorously prosecuted. Sinking the main incline goes steadily on.

BALTIMORE CONSOLIDATED.—Two more large new boilers arrived at the mine yesterday morning. The new hoisting engines are expected to be ready to start up in a very short time.

SILVER HILL.—The ledge in the north drift at the second station shows somewhat of an improvement.

SUTRO TUNNEL.—Main header to-day in 5,947 ft. The character of the ground in the face has changed very materially, being a mixture of clay and porphyry, with little water. It is so soft as to require no blasting, but constant timbering. The Burleigh drills are of no use in such material.

DAYTON.—Preparations are being rapidly completed for resuming the sinking of the main shaft. The dumps are kept full of ore, which is being shipped to the Woodworth mill on the Carson river.

MINT.—Sinking the shaft is making steady progress. The flow of water continues much the same, necessarily causing some delay in the sinking.

YELLOW JACKET.—Sinking the main incline is making steady headway, the bottom in hard blasting ground. It is now down 100 feet below the 1,640-ft. level.

CALIFORNIA.—The north drift on the 1,300-ft. level made the connection with the south drift from the Ophir this morning. Cross-cutting on that level will now be in order.

UNION CONSOLIDATED.—The main north drift on the 1,300-ft. level is in 645 ft. from the Ophir shaft, still following the west wall of the ledge with some very favorable and increasing prospects of ore developments.

LADY BRIAN.—The shaft is now down 140 ft. the sinking making fine progress.

SAVAGE.—The new station at the 2,000-ft. level is completed, ready to start a drift for the ledge.

FLORIDA.—Superintendent Nagle is now concentrating all work in sinking a new working shaft, with excellent progress, and grading off for hoisting works, etc., at the same time.

OVERMAN.—The main west drift on the 1,200-ft. level is still pushed vigorously ahead.

SOUTH COMSTOCK.—At the 190-ft. level the cross-cut east to-day is in 21 ft. the rock being somewhat harder, but fully as favorably looking as at last report, and giving as good assays.

LEO.—The rich ore streak in the face of the main drift is about 20 inches wide.

GLOBE CONSOLIDATED.—The ore dump is full and no more can be extracted until mills can be obtained to crush it. The west drift 170 ft. below the ore body in the winze is expected daily to strike the ledge.

MCMANS.—The main west tunnel is in a distance of 685 ft., the face in low-grade ore with seams of clay and quartz.

HALE & NORCROSS.—It is expected that everything will be in readiness for commencing the opening of the 2,000-ft. station by the first of next week. Daily yield, 40 tons of ore from the old upper levels.

GOULD & CUBBY.—The double winze is down 100 ft. below the 1,700-ft. level, the bottom in fine favorable looking quartz, with excellent indications of future ore developments.

JULIA.—The shaft is now down 60 ft. below the 1,000-ft. station. The south drift on the 900-ft. level, is showing considerable of an improvement since our last report.

CALEDONIA.—The main west drift at the fourth station level, is making steady headway without change of interest to report. Sinking the air winze from the third station level is making fine headway.

SUCCESS.—The east drift on the 300-ft. level, from the little shaft east of the mill, has just reached the ledge, but has not penetrated it far enough to determine its value.

KNICKERBOCKER.—The main west drift at the 400-ft. level, is in 900 ft., the quartz in the face showing quite an improvement in the last few days.

What a Man is Worth.

Some very interesting facts and figures are given in this *New York World*, in regard to the actual coin value a man is worth to community, and the loss it sustains if, from any cause, he should "go to the had." It says: The value of an able-bodied, clear-headed, healthy boy, fifteen years old, who has been to school the average length of time—six years—it is not easy to compute. He is educated in the simpler branches of knowledge. He may have also learned the rudiments of a trade, and become already, in a small way, what society has a right to expect he will become in a very few years in a large way, a producer. The mere private cost of his production is by no means small. He has had his share besides in the protection and safety of government and the accumulated comfort of the past, all of which has been lavished on him in the legitimate hope that he would in his time shoulder a part of the taxes, and aid in accumulating comfort and capital for the future. As a child, supposing that his life has been passed in the family of a mechanic, his expenses for fifteen years cannot fall much below this estimate:

THE COST TO THE FAMILY.

Board ten years at \$2, and five years at \$3 a week	\$1,820
Share of rent at \$14 a month in a family of five persons	504
Clothing \$20 for ten years, \$30 for five years	350
School books	30
Miscellaneous, sickness, etc., in all	275
Total	\$2,979

All this on the supposition that the family home has included three rooms only, that the family has had not more than five persons in it, all told, and that food and clothing have been of the plainest description, with enough of both to produce a healthy and vigorous growth; but with nothing to vary the monotony of fare limited to the necessities of life. He has cost as a member of a family, and that a family inexpensive and economical, about \$3,000; as a citizen he has cost a much smaller sum, but still one that is fairly appreciable.

THE COST TO THE STATE.

Schooling, six years	\$ 63
Taxes—State, fifteen years	165
Taxes—County, fifteen years	123
Taxes for national expenses, fifteen years	195
Total	\$546

As a person up to the age of fifteen has done nothing to earn the cost of the protection which a civil government gives in all its different branches, it is evident that, so far as he is concerned, the aliquot share expended on him is so much paid out to rear and educate; a direct investment which the community makes in him with the hope of a return. This investment amounts to at least \$546. It is direct, and easily computed.

There is another just as certain, but which cannot be so readily reckoned. The total valuation of the country is placed at \$30,063,518,507 in real and personal estate, and all this accumulated wealth of the parts works together to make life easier for the young man, who, till he is 15 years old, is adding nothing to it. He stands, too, the representative of another expense as tangible, but even less easy to give definitely. About half the population die before they reach the 15th year from birth. That is, to bring 500 persons to this point requires the birth and support for a longer or shorter time of 1,000; and the cost to the community of each at the age just mentioned is enhanced by the expense of those who fail to reach it. There are a hundred thousand other influences which cannot be reckoned in dollars and cents, but they exist none the less, and should be taken into account and kept in mind as part of the loss which the community at large suffers when one man fails to make any return for the talent confided to his care. The gross, perceptible, enumerable parts of his cost price are, to his family, in money, \$2,979; to his country and community, \$546; his share of the income from \$30,000,000,000 of property, and the partially developed life wasted and cut off that his might reach maturity. In all, the direct outlay is \$5,000—an understatement in two directions.

At 15 years a man may begin to be a producer; or, as the most common, most dangerous means by which he becomes nonproductive, he may also begin to be a drunkard. Neither are likely before this age, though either contingency may occur years earlier, as well as after. Society has spent some thousands of dollars directly on him, and devoted some millions of capital in providing him with an education and throwing around him influences which make his life a profitable investment.

But society has also taken some pains and trouble to render null and void its own efforts. It licenses numerous places at which the means of forming the habit of drunkenness can be found, and society pays four times as much to support them as it does to protect and educate the boy whom it has raised at such trouble and expense. He enters his eighteenth year a drunkard. As least, the State loses by his intoxication the direct investment of \$5,000. At 18, the man's labor is worth at least \$728 a year, or \$14 a week. All this is lost, and it amounts to the interest on nearly twice the sum spent for his education. The average life of a man addicted to the use of ardent spirits is about 17 years, and the sum lost in this way is \$12,376.

It is even greater than this. At 20 a person in health has an even chance of living 44 years; a dram-drinker's chances are cut down to about

one-third of this period; the difference being a loss of \$19,656, making the total deficit stand thus:

Original investment	\$5,000
Loss of labor during life (17 years)	12,376
Loss of 27 years of labor by drink	19,656
Total	\$37,032

The article also gives statistics which prove that the drunkard commits a very large proportion of the crimes of the community, and thus greatly enhances his expenses by the amounts expended in conviction, punishment, etc. Altogether it is a showing that should make the thoughtful pause before condemning too rashly the efforts of the reformers in this direction.

Indians Burying their Dead.

While the subject of cremation is attracting so much attention, some of our readers may be interested in knowing how some of the California Indians dispose of their dead. It is somewhat singular that although in some districts in the State some Indians burn, and others bury their dead, they all prepare them for final disposition in the same manner. A blanket is spread on the ground and the corpse laid upon it; a brother or some other relative, after folding the limbs upon the chest with the knees towards the chin, proceeds to bend the body and limbs together as tightly as possible. It is then wrapped in the blanket and placed upon the earth with the face upwards and exposed. The mourners continue their wild lamentations

INDIANS BURNING THEIR DEAD.

for a given time and then the men build a funeral pyre or prepare a grave.

If the corpse is to be burned, when the fuel is about two feet high all the sounds of grief cease, and amid a death-like stillness the men place the body on the pyre. Wood is then piled upon it until all but the face is covered. The oldest and nearest relative then sets the wood on fire. As soon as the smoke begins to ascend the discordant howling of the women becomes almost appalling; while the men in some instances stand in sullen silence, and in others join their notes of woe to those of the women. Then, as our illustration shows, all the relatives who are nearest to the consuming dead, with long sticks in their hands, commence a frantic dance around the burning body, occasionally turning it over and stirring up the fire, that the corpse may be consumed more speedily.

A writer states that the motive which impels them to this, is that they believe there is an evil spirit who is continually contriving to give them trouble, and who will keep them from the "happy hunting grounds" if he can. They think the heart is the immortal part, and that he seeks to make it a prisoner; so they endeavor by noises and motions to attract the attention of this spirit while the body is burning, as it is at that season that the heart leaps out, and if the evil spirit's attention is distracted by their manœuvres, the heart makes its escape and is eternally safe. This is the reason for the hideous noises and waving of cloths practiced during the process of burning.

After the body is nearly consumed, the blackened remains are taken from the fire and rolled in a cloth and blanket, to cool it a little, when his wives separate the remaining and unconsumed portions of the body, and around each piece wind a long string of beads. Every particle is then placed in a basket that has been beautifully beaded and worked for such an occasion, with any other valuables that have been reserved. This being done, and the fire rebuilt, the basket and its contents are placed upon it; and while this is being consumed, cloths, blankets, dresses, beads, arrows, knives, pocket-handkerchiefs, and everything else that has been touched by the dead body, are added to the flames. When these are burned, every unconsumed log is carefully scraped, all the ashes swept together, and the whole, with the exception of a small portion reserved for mourning, is placed in another basket, and then buried.

The reserved ashes, after being mixed with pitch obtained from pine trees, are spread over the faces of the female relatives as a badge of

mourning, and which, although very hideous to our sight, are sacred to theirs, and allowed to remain until they wear off.

Beach Mining.

A correspondent of the *Call* writing from up the coast speaks as follows of the beach mining: The mining interest is in its infancy. That there is gold in paying quantity there is no doubt, not only on the beach, but back in the interior, where no prospecting has been done, although it is known that in the early days of the settlement, Indians would dispose of large parcels of heavy gold, which they stated was hammered out of rock. So numerous are the other interests about Coos Bay that mining is neglected, except at Reudolph, twelve miles down the coast, where a number of claims are working on the beach successfully. But the most remarkable is the "Old Beach," as it is called, where several claims are located. One, worked by Laue & Co., is exceedingly rich. To understand what the "Old Beach" is, it is necessary to state it was only discovered through accident, by finding gold in the black sand of a creek fully three miles from the ocean beach. To reach there a thickly timbered country must be passed, and a person would never imagine that it had once been a beach; but all doubt would be settled by a visit to the claims, where each stratum of sand is the same as it is on the regular beach, with a greater depth of black golden sand.

The formation must be very old, to judge by the banks of the mine, which are 50 feet high and thickly timbered on top. The formation

The Comstock.

The Comstock lode is about entering upon a new career of productiveness, of which the great Crown Point ore body is the prelude. The 1,400-foot level new confirms the old impression that that body is continuous, and those of the Virginia mines are opening out similar convictions as to that end of the lode. The public mind is apt to be impatient of the time which, with the best improvements in means that are constantly taking place, is required not only to develop new levels in old ore bodies, like that of the Crown Point, but entire new bodies like that of the Consolidated Virginia, California, etc.; and the gambling element in every lull of advancement takes the "heer" shape, notwithstanding the experience that the inevitable rise destroys the bear operators. As we look back to the "flush times" of the Comstock we find that up to April 1, 1866, it had given \$51,380,588 in bullion to the world. The mines were then 600 feet deep. In the last four years they have given out, from a depth of 1,800 to 2,000 feet, \$56,187,208, and the producing points increase in number. There are constantly new inventions and new applications of old inventions which facilitate the exploration for ore, its extraction, production and transportation.

The modes of operation at present in no degree resemble those of ten or even five years since, before the experience and genius of men like Superintendent Fair. What were supposed insurmountable obstacles are easily overcome; what were difficulties are swept away. The cost of extraction and reduction sinks under inventions or discoveries like Mr. Fair's fuel-saving engine; and ores that were rejected formerly are made to yield a profit. "The stone that was rejected becomes a corner in the hands of the builder." Depth has now no terrors for the expert miner, and every body of ore turned up is no longer worked wastefully and unintelligently, but is made to yield all it is worth, or, as our gambling bear friends would say, "played for all it is worth." Under the inventive skill and energetic action of American management more progress has been made on the Comstock in ten years than in other parts of the world in similar formations in a century. It results, as a matter of fact, that shares on the lode are daily rising in intrinsic value. It is no longer a question of shares of a company in an isolated spot on the lode, but shares in the lode as a great whole, every portion of which will, under the growing science of quartz mining, give back its full value. Men invest money in unimproved lands because they know the growth and population, with its increasing wants per head, will impart to the land an ever swelling value. So of the Comstock lode. The inexperience and doubts of the past, which gave a fluctuating value to different bodies, have consolidated into present conviction of the permanent value of the whole lode. The doubt only is as to the most immediate realization. Every foot on it will, sooner or later, have its well determined value. "A share on the Comstock" will be a well defined property. —*Alta*.

Copper in Nevada County.

As long ago as 1861 or '62, some parties engaged in digging a well down near the Zinc House in the lower part of this county, came upon a peculiar—to them—substance, which created considerable talk in that neighborhood and upon examination of a party who had recently been in the Copperopolis mines was pronounced genuine copper ore. At that time the idea was prevalent that a copper mine was far more desirable than any gold mine and this discovery at once set the community astir for more copper indications and more or less were found all along that range of the foothills. The discovery was known as the Well lead and considerable work done for a year or two; enough to prove that a fine body of ore existed there, but copper went down in price to such an extent that this in common with other well known properties in California failed to remunerate the owners and work ceased thereon.

About a year ago Prof. G. F. Deetken, long well known in this place as a metallurgist of superior ability, took charge of this mine for a company of capitalists of this town and San Francisco and since that time work has been pursued so systematically as to render the success of the enterprise certain. They have secured patent from Government to their mine and recently incorporated with Wm. Watt, John C. Coleman and F. G. Beatty of Grass Valley, and E. V. Sutter and Robert Morrow of San Francisco as Trustees. Prof. Deetken will continue to act as Superintendent. They have a new shaft down 45 feet, the ledge at this point showing a width of over 70 feet. The ore is said to be free from arsenic and antimony and so better adapted to working than many copper ores. Tests have been made on a large scale, proving that this ore can be smelted at the mine and pure copper sent to market with good profit. Mr. Deetken is now building a roasting furnace of 25 tons a day capacity, combining the best features of well tried furnaces with some of his own invention, which, together with the larger blast furnace now also being erected, will render the works quite extensive and make the little town of Spenceville quite a lively place soon.—*Foothill Tidings*.

HAYCOCK, of Gopher Hill, Plumas county, melted out a \$3,500 bar the other day, at Spanish ranch, the result of two small "clean-ups."

The incrustation of boilers is a subject which interests so many classes of manufacturers that every chemical discovery which promises to prevent or remove the scale is heartily welcomed. The use of lime for rendering hard waters soft is not new, but the means of determining the amount required, and upon which all depends, have been greatly simplified by the use of volumetric means. The best preventative of scale in boilers is, however, tannate of soda, which is now furnished in quantities at prices which permit of its extensive use.—*Journal of Ap. Chem.*

RICH ORE.—Here is a little item that doesn't occupy much space, but we should like (for San Juan's sake) to see something in the *Prospector* that will rival it: One and a half tons of ore from the Saco, crushed at Cree & McCann's, last Tuesday, yielded at the rate of three thousand five hundred and thirty-five ounces per ton. The ore was taken from the workings of Bennett & Co.—*Colorado Miner*.

USEFUL INFORMATION.

Hints on Building a Stone House.

The use of stone in building dwelling-houses finds more opponents than any other material. To the architect's question, "Of what material do you propose to build?" the reply of the client is almost invariably, "Stone;" but a few facts concerning the cost very soon cause the owner to abandon that material, and take one less expensive. A stone house, properly built, is undoubtedly the most expensive edifice that can be erected. It has its advantages and its faults; and, unless it is carefully and thoroughly put together, the latter certainly predominate. Its two principal recommendations are its fine, substantial and showy external appearance, and the facility with which creeping vines may be grown upon it. The building, not requiring paint, permits these vines to grow at random, producing a much desired romantic effect. It cannot be claimed that such a house is any warmer in winter, or cooler in summer, than a brick one; while in comparison with a frame house it maintains the same relation as a cast iron stove does to a sheet-iron stove. The one being much thicker than the other, absorbs more heat, and hence we are required to wait longer before feeling the benefit of the fire; but when once heated, it retains it much longer. The interior of a frame house changes much more readily under the influence of the outside atmosphere. We have seen the walls of the interior of a stone house in midsummer covered with moisture caused by a sudden change in the atmosphere from a close murky atmosphere to a cool, clear one, causing probably a difference of ten or fifteen degrees in less than half an hour, thus producing condensation on the walls. This could not occur in a frame building, both on account of the material of which the walls are constructed, and also of the rapidity with which the outside can affect the inside. In this case the moisture would be removed, not precipitated. The walls of a stone dwelling-house should never be constructed of rough rubblework, for the reason that it is almost impossible to thoroughly fill all the joints with mortar; the stone being rough on the face, does not allow the water to pass off freely, and the result is that, in a driving storm, a very small opening, hardly large enough to admit the small blade of a pen-knife, will take in a large quantity of water and produce dampness. In the construction of churches and other buildings, not dwellings, we have often worked long and diligently to find these small crevices, to stop the flow of water. Stone naturally absorbs moisture, and that, together with any leakages that may exist, produces too much dampness for health or comfort. The proper construction for the walls of a stone dwelling is to have the beds and joints squared, (what is termed squared random-work.) This enables the workman more surely to fill the joints with mortar. All the outside joints should be thoroughly pointed with cement before the building is occupied.

A stone house can be constructed either with hollow or with solid walls. The former method is the plan we generally recommend, for the same reasons as have been given for its adoption in a house constructed of brick. The outer wall should not be less than 16 inches thick, of stone; leaving a space of three inches, and backed up on the inside with four inches of brick work; the inside and outside work to be bound together with iron ties, the same as for a brick house, only that the ties should be about 15 inches long. If a stone house be built in this way, and the same precautions taken as described for a brick house, no fear need be entertained of dampness; but where this system of hollow walls is adopted, and the inside and outside work is bound together by stones going through the whole thickness of the wall, or with binders of brick (instead of iron), dampness is sure to ensue. Hollow walls to be thorough and effectual must have outside and inside work entirely separate from each other.

To build a house with stone use great care in laying up the walls. As this is, unquestionably, the most thorough method of building, it is also (except in some rare cases) the most expensive, even in cases where stone is obtained for only the expense of carting; the cost of the brick for a brick house being more than counterbalanced by the additional labor required in cutting and dressing the stone, and in handling and building it into the wall. In conclusion, we would advise those contemplating building of stone to do so in the most thorough manner. If the cost is too great, do not economize by building cheaply, for the sake of having a stone house. It is far better to adopt a cheaper material. A well-constructed frame house is much better and healthier than a cheap stone house.

Whatever you do, in the use of any kind of building material, do thoroughly, and you will be relieved of much care and perplexity. Your enjoyment of your home will be much greater, your health promoted, and everything which tends to give that quiet and repose for which home is chiefly valuable will be greatly increased.—*American Homestead.*

To obtain anhydrous or absolute alcohol, boil strong alcohol with quick lime for one hour in a vessel with an inverted condenser, and then distill.

The Strength of Materials.

Gold may be hammered so that it is only 1,360,000 of an inch thick. A grain of iron may be divided into 4,000,000 parts. Still chemistry tells us that there are ultimate parts called atoms or molecules, which are absolutely indivisible. These atoms are attracted to each other by the attraction of cohesion, and repelled by the force of repulsion. By the action of both these forces the atoms are kept in a state of rest. The solidity of a solid depends upon the fact that each pair of atoms are in this state of equilibrium. These atoms are supposed to be of an oblate, spheroidal form. An iron bar would support its own weight if stretched out to a length of $3\frac{1}{4}$ miles. A bar of steel was once made which would sustain its own weight if extended to a length of $13\frac{1}{2}$ miles.

Our ideas of great and small are no guide to be used in judging of what is truly great and small in nature. The Bunker Hill Monument might be hilted to over a mile in height without crushing the stones at its base. When bars of iron are stretched until they break, those which are the strongest increase in length less than the weaker ones. A piece of wood having a breadth and thickness of three inches and a length of four feet, if supported at its ends, would be bent one millionth of an inch by a weight of three pounds placed at its center, and a weight of one-tenth of an ounce would bend it one-seven-millionth of an inch. Prof. Norton described a machine for testing the variation of sticks of wood. The machine consists of levers and screws so contrived that the amount of weight brought to bear upon the stick can be accurately measured, and the variation of the stick from a straight line can be measured, even though it do not exceed one seven-millionth of an inch.—*Jour. of Ap. Chem.*

The subject of food, its preservation and adulteration, has attracted more attention than formerly. M. Sacc proposes to use acetate of soda for preserving meat; another substance suggested is a mixture of boracic acid and common alum, while Lajourroie has found that one per cent. of magnesia will preserve meat for several months. The passage of an adulteration act in England has directed the attention of analytical chemists there to the study of the best means of detecting adulterations. At present adulterations in tea are attracting so much attention that it is very probable that much of the worst tea in the world will seek a market in America, where no such laws exist. Attention has been frequently directed to the dangers attending the use of impure water, and we have from time to time indicated the best methods of testing potable waters, and of purifying those that require it.

TO MAKE PAPER TRANSPARENT.—The best kind of paper is the class known as wove, not laid paper. A varnish formed of Canadian balsam dissolved in turpentine supplies an excellent means of making paper transparent. The mode by which we succeeded best was to apply a pretty thin coating of this varnish to the paper, so as to permeate it thoroughly, and then give it a good coating on both sides with a much thicker sample. Keep the paper warm by performing the operation before a hot fire, and apply a third or even a fourth coating until the texture of the paper is seen to merge into a homogeneous translucency. Paper prepared in this way has come nearer than any other to our ideal of perfection in transparent paper.—*British Journal of Photography.*

NEW APPARATUS FOR REGISTERING THE DIRECTION OF CLOUDS.—M. de Parville proposes for this purpose a board some 12 inches long by eight inches broad, fixed on a suitable support. A square of unpolished glass, placed vertically, divides the plane in two equal parts. The left hand side of the latter is covered with a mirror; on the right is a sheet of paper. As the clouds pass above the horizontal glass, they are reflected; and at the same time the observer sees their images on the vertical glass projected on the paper. It is only necessary to trace their direction on the latter with a pencil. On the mirror is engraved a compass card, which is also reproduced on the paper, and a small magnetic needle is suitably arranged so as to adjust the apparatus.

PRESERVATION OF VEGETABLE POWDERS.—Mohr's method of preserving vegetable drugs consisted in placing in the drawers with them preformed tin boxes containing quick lime. Louis Cornish, pharmacist at Diest, proposes a modification of this plan, which is especially adapted to the preservation of powdered drugs. The bottles in which the drugs are kept are fitted with large hollow stoppers, which are filled with fragments of quick lime. The large opening through which the lime is introduced is secured by tying over it double thicknesses of linen and filtering paper.

REPAIRING MIRRORS.—To replace the small patches of quicksilver often found removed from the back of looking-glasses, clean the damaged spot by very careful rubbing with fine cotton until there is no trace of grease or dust; then with the point of a knife cut the size of the required piece of the silvering off another glass; a small globule of mercury (the size of a pin's head for a surface the size of the finger nail) is dropped upon the cut piece. The mercury penetrates as far as the cut, and allows the piece to be removed. It is then gently pressed on the spot with a piece of cotton.

GOOD HEALTH.

Can a Person be Anesthetized During Sleep?

This is a very important medico-legal question, and is ably discussed, though not conclusively settled, by Professor Dolbeare, in the January number of the *Annales d'Hygiene*. Professor Dolbeare performed several experiments, and found that sleeping animals were readily aroused by the presence of even small quantities of chloroform in their immediate vicinity. The cases of three patients are also given, who while sleeping were readily aroused by applying small quantities of chloroform at no great distance from the nostrils. In a second series of experiments made on seven patients, ten drops of chloroform were poured on a napkin folded in four, which was gradually brought to the vicinity of the air passages, so that all air inspired had traversed it. In all these cases patients were suddenly aroused from their sleep, come immediately and only one after the eleventh inspiration.

A third group of cases, consisting of twenty-nine patients, was next experimented upon, furnishing different results. These are given in some detail, but it will suffice to say that it was found that in ten out of the number, that is, in more than a third, complete anesthesia could be induced without awakening them. Dexterity in the mode of procedure seemed to have something to do with the proportion thus obtained, for this increased progressively with the number of cases experimented upon.

"New researches will still be required in order to establish the influence which may be exerted on the results by the age of their subjects, their sex, their prior condition of health, personal habits, etc. The purity of the chloroform employed is also a matter of importance. While thus appealing to future researches, your reporter, making certain reserves, still feels he is authorized in drawing a somewhat positive conclusion. Scientifically it is difficult, but often possible, to render persons insensible by means of chloroform who are in a state of natural sleep. Certain precautions, the employment of a very pure article, and great practice are conditions that favor the success of the attempt. It is probable that certain subjects are absolutely refractory, that is, it is impossible to anesthetize them, in spite of every precaution that can be taken. Others, on the contrary, and especially young children, easily undergo anesthesia without being aroused from their sleep by the irritation which the anesthetic produces in the air passages. Under the criminal aspect it is certain that chloroform administered to sleeping persons may facilitate the perpetration of certain crimes. It is, however, probable that the conditions favorable for anesthesia will be rarely combined on the occasion of criminal attempt. But before the tribunals the expert should declare that it is possible, if not easy, to render a sleeping person sufficiently insensible by chloroform to allow his becoming the victim of a criminal attempt."—*Phil. Med. Reporter.*

ARTIFICIAL FEEDING OF CHILDREN.—Nursing by the mother is the only natural feeding, and it can not be substituted by any other with safety to the health of either the mother or child. Wet nursing is only to be resorted to when the mother's milk is not suitable, and when a proper wet nurse can be obtained. The so called "prepared foods" with their flaming advertisements and testimonials, oftentimes egotistic, and accompanied, as in one instance, by the picture of a wonderful baby "brought up entirely on this and no other food"—all of these originate in a desire to meet the wants of children deprived of mother's milk, and often stand in the way of a mother's duty of nursing. The country is flooded with them. Some are harmless, many dangerous, and a few useful. The thoughtless indorsement of physicians is easily to be deplored. A perfect substitute for mother's milk has not yet been made, and it is doubtful whether it ever will be. An exact analogy in solid and fluid constituents can not take the place of human milk, with its inherent, unexplainable, life-giving principle.—*Sanitarian.*

USE OF SWEET OIL AS A DRESSING FOR WOUNDS.—Dr. Jos. W. Howe has recently introduced at this hospital ordinary sweet oil for the treatment of all kinds of wounds. It has several advantages over any of the other dressings in use, and apparently yields better results. The advantages are, that it keeps the air from the wound, and at the same time is a grateful dressing to the patient. It also promotes healthy granulations. The mode of application varies with the variety of wounds for which it was intended. In necrosis, after the sequestrum is removed, the cavity is filled with the oil, and a lint tent introduced. Every day the oil is renewed. In one case of necrosis of the lower jaw this procedure was had recourse to, and, shortly after, the patient was attacked with facial erysipelas, but, strange to say, the side of the face which had been operated on was not affected. In incised wounds, the edges are brought together, and soaked in oil used as an external dressing.

Too much lemon juice if taken in an empty stomach might do harm, but it would be slight. Taken after the food is in the stomach there would be no objection to it on this ground.

Longevity of Man.

The great physiologist, Flourens, concluded that the natural extreme age of man is 100 years, and his conclusions have been adopted by Faraday and all other philosophers and physiologists. The duration of life is measured by the time of growth. When once the bones and epiphyseae are united, the body grows no more, and it is at twenty years that this union is effected in man. In the camel it takes place at eight, in the horse at five, in the lion at four, in the dog at two, in the rabbit at one. The natural termination of life is five removes from these several points. Man being twenty years in growing, lives five times twenty years—that is to say one hundred years; the camel is eight years in growing, lives five times eight years—that is to say forty years; the horse is five years in growing, and lives twenty-five years; and so with other animals. The man who does not die of sickness, lives everywhere from eighty to one hundred years. Providence has given man a century of life, but he does not attain it, because he inherits disease, eats unwholesome food, gives license to passions, and permits vexation to disturb his healthy equipoise; he does not always die from age, but kills himself. Professor Flourens divides human life into infancy, youth, virility and age. Infancy extends to the twentieth year; youth to the fiftieth, because it is during this period that the tissues become firm; virility from fifty to seventy-five, during which the organism remains complete; and at seventy-five old age commences.

To some persons it may appear that to extend virility to seventy-five years and let old age commence then, is rather extending the numbers too high; but we suggest that all persons descending from a healthy stock of family, and who have lived wisely, have certainly not spent their virility before the age of seventy-five; who is there who has not often had occasion to admire some venerable white-haired men of about that age, who are fully equal in bodily health, and especially in mental vigor, to those who have lived only half that period of time.

Usually the vitality runs down quite rapidly at about that period; life then lasts a shorter or longer time as the diminution of reserved force is hastened or retarded either by the then existing conditions surrounding the individual or by the impression which his system has received by his previous manner of life, or experiences undergone.

It is evident that only those for whom every thing has conspired in their favor can attain the limit of one hundred years; and this shows at once why these cases are so rare; man is so complex a being and the causes of derangement so multifold, that it is rather to be wondered at why many who by no means live wisely do not die sooner. This is actually the case; but a naturally strong constitution often overcomes the results of the most pernicious habits, as the drinking of alcohol, excessive smoking, etc., which very soon destroy the weak, who act very foolishly, when they try to follow the example of those who survive in spite of these follies.—*Manufacturer and Builder.*

Typhoid Fever.

The prevalence of this justly-dreaded disease in several localities just at present leads us to offer a few suggestions as to its prevention by proper hygienic measures. That it may be defied in almost every instance by observing proper precautions, there is no doubt at all. All admit that it has its origin in decaying animal or vegetable matter; probably the former, possibly both. This fact was forcibly impressed on our mind during a late trip in the country. In a remarkably healthy neighborhood we found two families quite a distance apart, too, both having several members down with this disease. One glance at the location of each, instantly told why they were there attacked while their immediate neighbors escaped. The houses in both instances were old and decaying, and stood in such a position that all water which fell near, and all refuse from the houses, flowed directly to them, and were absorbed by the soil underneath. Here the accumulations of years, perhaps, were rotting; both places had a damp, foul smell about them, and the cause of the fever was at once apparent. Farmers are too apt to think that drainage is all well enough for large cities, but of no use about a farm house, whatever. This is all wrong; and the first desideratum in choosing a location for a dwelling ought to be that there shall be efficient slope or elevation to secure good drainage. If this is not practicable, then the structure should be placed at a sufficient height from the ground, to allow free ventilation beneath; and this should always be left unobstructed; securing the warmth of the building by very tight floors. Another simple precaution of great value is to have the pit or sink, which almost every family has for the reception of refuse matter, so arranged that no foul vapors can escape. This can be arranged by having a double elbow in the pipe leading to it, so that there will be a constant stratum of water in the elbow, to intercept any noxious or unhealthy gases, as they escape. By allowing no animal or vegetable matter to decay around the house, and by keeping the ground dry by proper drainage, with such other little sanitary precautions as will suggest themselves to the ordinary thinking mind, this dreaded, lingering, prostrating disease might almost be banished from the land.

TABLE OF CONTENTS.

GENERAL EDITORIALS.—The Clay Street Railroad; Hinkle's Hydraulic Hoist; The Burleigh Mining Drill; Tintio Mines of Utah, 337. Indians Burying their Dead, 342. Fish Importations; The Emma Mine; Work on Mining Claims; Stickeen River Mines; Important Mining Decision, 344. Reconnaissance—Exploring Made Easy; Mechanics' Institute; Improved Faucet for Casks, 345. Suro Tunnel, 348.

ILLUSTRATIONS.—The Burleigh Rock Drill, 337. Indians Burying their Dead, 342. Brize's Improved Faucet, 345.

CORRESPONDENCE.—The Panamint Silver Mines, 338.

SCIENTIFIC PROGRESS.—Electroplating; Boiler Explosions; The Chemical Classification of Iron, 339.

MECHANICAL PROGRESS.—The Whims of Machinery; Paper-Hanging Machine; Stove-pipe Thimble; Perpetual Motion; Machines to Make People Honest; Plans for Ships' Boats; Completion of an Immense Safe, 339.

MINING STOCK MARKET.—Table of Daily Sales and Prices and Comparative Prices for the Week; Notices of Assessments; Meetings and Dividends; Review of Stock Market for the Week, 340.

MINING SUMMARY from various counties in California and Nevada, 340-41.

USEFUL INFORMATION.—Hints on Building a Stone House; The Strength of Materials; To Make Paper Transparent; New Apparatus for Registering the Direction of Clouds; Preservation of Vegetable Powders; Repairing Mirrors, 343.

GOOD HEALTH.—Can a Person be Anesthetized During Sleep? Artificial Feeding of Children: Use of Sweet Oil as a Dressing for Wounds; Longevity of Man; Typhoid Fever, 343.

MISCELLANEOUS.—The El Dorado Ditch Company; Bullion and Charcoal at Eureka; Arizona Placer Mines; The Eureka Consolidated Mine; Started Up, 338. What a Man is Worth: Beach Mining; Rich Ore; The Comstock; Copper in Nevada County, 342. The Honoma Valley Mines; New Smelting Works; Coal Mines at Oco Bay; A Chapter of Accidents; A Case of Lead Poisoning; Coal Cutting Machinery; Hidden Treasure Mining District; A Specimen Newspaper Item, 346. The Mines of Tasmania, 347.

Fish Importations from the East.

An aquarium car will start on its journey to his coast on the 3rd of June, to make a second attempt to cross the continent with a load of living fish. The car will be in charge of Livingstone Stone, the gentleman who was in this State last year obtaining salmon eggs for the Eastern States. The car in which the fish are to be brought this time is 40 feet long, with broad head, passenger trucks, twelve wheels, air brake and Miller platform, and is well made, and appropriately fitted for the purpose. The salt water fishes on the list to be taken are as follows: Lobsters from Massachusetts bay; oysters from same place; soup from Martha's Vineyard; striped bass, New York harbor; tan togo, Martha's Vineyard; salt water eels, same place; king fish, weak fish and blue fish from New York harbor.

The fresh-water fish to be brought are black bass, glass-eyed pike and horn-ponies, from Lake Champlain; eels, from the Hudson river; cat-fish, from New Jersey; Shad, from the Hudson river; red minnows and alewives, from Massachusetts.

To take across almost any of these varieties would be a great care and labor; and to take across the whole is quite an undertaking. The car will leave Charleston, N. H., about the 3d of June, reaching Sacramento and this city about the 10th. It is to be hoped that the experiment of bringing these fish across will be more successful than the attempt was last year, when the car was wrecked, and those of the fish which did not fall into the river where the accident occurred, were destroyed.

A PATENT to the first placer claim ever located in Utah was issued at Washington on the 30th ultimo.

The St. Helena gold mine, Napa county, is to have a mill, and ground has been broken for the foundation.

SEVENTY men are employed at the Benicia Tannery.

The Emma Mine.

While we regret the late unsatisfactory reports concerning the workings of the famous Emma mine, in Utah, we are at the same time glad to see that the reports of eminent mining experts hear out the opinion of the present manager, who has been much maligned for saying what he believed to be true. Interested parties in Salt Lake city and elsewhere have done more than enough to inspire holders of stock in the Emma with confidence in the future of the mine, when there was no foundation for this confidence. Apparently well authenticated accounts of rich strikes in the Emma have appeared in the press of this country and England at different times, when in truth no such developments were being made, or from indications were likely to be made.

In a certain degree the Americans have been disgraced by the action of persons of their own nationality in matters connected with this mine; but past transactions have been quite sufficient to injure the mining interests of Utah, and in fact this whole coast, in the opinion of the English capitalists, without any fresh instances of want of good faith on the part of these interested parties. Therefore it is greatly to be regretted that certain persons—not one but many—have taken such trouble to misrepresent the actual condition of the mine in order to induce the English shareholders to invest heavily in a losing concern.

During the past year explorations have been going on, levels run, winzes and shafts sunk, and the sides of the ore body thoroughly prospected, all of which work has proved very unsatisfactory as regards the future prospects of the mine. The ore reserves in sight in the mine are very small, and the Attwood winze at the bottom of the ore body has failed to show any ore. These facts have been transmitted from time to time by the present manager of the mine, Mr. Attwood, and his full report was probably made on the 15th instant in London. When this report comes to hand we will quote liberally from it and show the diagrams of the mine, explaining the internal workings, etc. Meanwhile we are enabled through the kindness of a friend to quote as follows from the reports of three eminent mining experts, who all agree with the manager as to the future supply of the mine.

Report of Clarence King, Director of the United States Geological Survey of the 40th parallel, dated June 11th, 1873: "In conclusion, I can only reiterate that the great Emma 'bonanza' the object of such wide celebrity, the basis of such extravagant promises, is, with insignificant exceptions, worked out, and the future of your company is hung on a mere geological chance, which may be eternally against you, and if in your favor, may only be secured by the wise expenditure of much time and money."

Report of E. S. Blackwell, Esq., Manager, Ophir mining and smelting company of Utah, (Limited), dated June 7th, 1873: "The future of the mine depends entirely upon the virgin ground, and to explore this you must be prepared to wait some time and spend a large amount of money in developments."

Report by Andrew Murray, Esq., F. L. S., etc., dated August 6th, 1873: "In my opinion the famous Emma mine is exhausted, and nothing more is to be extracted from it but the leavings of the old workings, the scraping of the walls, the ore which may have been entombed by the cave, the old fillings and the second-class ore on the dumps."

From report of George Attwood, manager of Emma mine, dated May 11th, 1873: "That your property is in a most unfavorable condition, and that the former management cannot be too highly censured for the way in which your mine has been worked, as they have exhausted all the pay ore accessible and not even well timbered or secured the same, and have neglected to make 'explorations to the deep.' The result of all this is that the future prospects of the mine are most gloomy, and until the explorations are carried much further ahead, cannot conscientiously give any encouragement."

The statements made in these four reports have been borne out by the result of the workings of the past year. As to what the directors of the mine intend doing we cannot say, until the result of the meeting in London on the 15th inst. is made known.

OREGON.—A number of capitalists are in Baker county looking at the mines. They contemplate the erection of a silver mill in Rye valley.

A new silver discovery has been made at Rosita, Colorado. Ore taken out two feet below the surface shows a value of about \$1,100 per ton.

A "POCKET" in the Kincaid Flat mine, Tuolumne county, yielded \$1,200 last week. One piece weighed two ounces.

REPORTS from the Amador quicksilver mine still continue to be more favorable as the work of development goes on.

ONE hundred and thirty car-loads of ore are daily shipped over the Virginia and Truckee railroad.

THE yield of the Gwin mine, Calaveras county, averages \$1,500 per day.

Work on Mining Claims.

The mining community is very much exercised as to the amendment to the mining law of May 10th, 1872, which extends the time for the first annual expenditures on claims to June 10th, 1875. As the law now stands the time for the first annual expenditure is June 10th, 1874. There is now, at the time we go to press, (Thursday night,) some indecision as to what has been done with the amendment in Congress. As far as we can learn it was recommended favorably by the Senate Committee on Mines and Mining; passed the Senate, and is now awaiting final action by the House. This being the case, in all probability the amendment will be adopted and the time be extended to June 10th, 1875.

Many miners not anticipating any further extension of time, have done the required work. Others again, are anxiously awaiting the result of Congressional action, with the hope that they will be allowed another year's grace. Many are, however, prepared to begin work on the 10th of June, which the law allows them to do, and still hold their claims. Some are beginning now to do their work, for fear the amendment to the law will not pass in Congress. Those who propose commencing their work on the 10th of June, had better be prepared to be on the ground early on that day, since numbers of men have "spotted" promising claims, and stand ready to locate them in case the owners do not do the work required by law.

The placer miners are in a quandary as to whether their claims are on the same footing as lode claims. Some owners have done work on their placer ground to be on the sure side; whilst others have concluded that although the law may include placer claims it does not specify them, and they therefore consider themselves free of the operation of the law as far as their annual expenditure is concerned. This question will, however, have to be settled by the Commissioner of the Land Office, who will probably take some action in the matter very shortly. There is little doubt that the clause was intended to apply to all classes of claims; but in reading the law the natural inference is that only lode claims are meant, so that many owners of placer mines intend taking advantage of the want of clearness in the law.

The Stickeen Mines.

News of a very discouraging nature comes from the Stickeen river mines, and if reports be true, those who intended going thither and changed their minds, may congratulate themselves on their luck. It is stated that about one hundred disappointed miners arrived at Olympia on the 16th inst. from these mines and they say the Stickeen mines are the worst "bilk" ever gotten up on the Pacific coast; that hundreds of men are in the mines without a dollar or a pound of provisions and that great suffering must consequently follow.

It seems as if repeated bitter experience would prevent most prospectors going to these periodical "excitements" without at least money enough to get back again; more especially when the mines are in as inhospitable and distant a district as the Stickeen river country. The long winters were enough to deter most men, but the stories of fabulous richness—always prevalent about new mines—led many others to try their fortunes in the snowy regions of Dease's lake. It is probable, however, that some of the men who went to these mines must have made something, for a month or so ago a correspondent wrote that all the claims worth anything were taken up. We suppose that the late arrivals at the mines, most of whom expected a good claim immediately, must have been disappointed in seeing all the available mining ground already located; and fully realizing by that time the rigor of the climate of the region, they made up their minds to return. Of course such men will give the country a bad name, as those who are lucky will give it a good one. Many enthusiastic prospectors will not take the words of other parties about new mines but must see for themselves, and in so doing they often get "bit" badly. It is strange, but nevertheless true, that all the mining "excitements" in British Columbia and that region have turned out badly, and a large proportion of the men who went to the different localities, returned poorer but wiser men.

MINING is quite active in the vicinity of Garrote. Several good veins will soon be opened and put in working order.

HUNTER and Stewart, of San Francisco, have purchased the Italian mine, located at Deer Flat, Tuolumne county, for \$30,000.

TWENTY miles of the Palisade and Eureka narrow-gauge railroad have been graded, and for six miles the track has been laid.

SEVERAL very important water right suits are pending in the District Court of Plumas county.

A TEN-STAMP mill is being erected on the Zacafero mine, at West Point, Calaveras county.

Interesting Mining Decision.

A decision of much interest to miners was recently made by Judge Belden, of the Sixteenth Judicial District, the property involved being worth about \$1,500,000. The contested property is located in the town of Cerro Gordo, about six miles east of the north end of Owen's lake, Inyo county. It owes its origin and magnitude to mining interests. These mines were discovered in 1855. The most valuable mine yet worked is the Union. Its working-shaft is down 500 feet, and the ledge and works of the mine are valued at fully a million and a half of dollars. On the same hill and running across the Union, is the San Felipe mine. The Union was discovered by one Beltran and two of his workmen, who were engaged in sinking a shaft on the San Felipe. They went on working apparently harmoniously together, although some of the locators in the San Felipe complained because they were not included in the Union location.

In February, 1873, an action in ejectment was commenced in the Sixteenth District Court, by the San Felipe Mining Company, against M. W. Belshaw and others, owners of the Union mine. At the time this suit was instituted, Belshaw was in possession of the San Felipe mine under a sheriff's deed, but the San Felipe company set up a redemption of the property. The case came on for trial at Independence, in July last, and lasted ten days. There were thirty-six witnesses examined, and the testimony in the case is contained in about 6,000 folios. The attorneys for plaintiff were B. S. Brooks and John McHenry, of this city, and Mr. Freeman, of Kern and P. W. Bennett, of Inyo county. W. H. Patterson, of this city, and Patrick Raddy, of Inyo, represented the defendants.

J. J. Moore, Recorder of the district at the time the claim was located, testified that he wrote the notice of location, and that he was shortly afterward called to measure the claim. He commenced at the south San Felipe shaft, ran up the hill in a southeasterly direction 1,200 feet. The vein was silver quartz, from eighteen inches to two feet thick. Twelve hundred feet were also laid off in the opposite direction down the hill. There were no croppings to be seen northerly from the shaft.

Bentura Beltran, the discoverer and locator of the San Felipe and Union mines, testified that he posted the Recorder's notice above the original shaft on the quartz vein. He could trace the vein some 600 feet up the hill, and did work there in 1866.

Giardo Valenzuello snuk the first shaft on the San Felipe vein, in 1866. He found silver ore, with specks of lead; vein varying from 2 to 2½ feet thick.

Pedro Astorga, one of the locators, said he claimed the vein for silver, and he followed the croppings a distance of 1,200 feet.

The jury, after an absence of two hours and a half, found a general verdict for plaintiffs, which, under the construction of the Court, gave plaintiffs possession of both mines. A stay of proceedings was granted until argument on motion for a new trial could be heard. The motion came up for argument in San José, on December 27th. Judge Belden took the matter under advisement, and a few days ago he filed a voluminous opinion, denying the motion, and finding no warrant to set aside the verdict. Meanwhile defendants have been in possession of and working the mines. The defendants have filed an appeal bond in the sum of \$50,000.

In the decision the Judge said: "If there is one class of cases above another in which the verdict of a jury, fairly obtained, should not be lightly set aside, in my opinion it is a mining case, in which propositions of disputed identity are supported by testimony of this character."

If the fact that I might have reached a different conclusion from the same testimony, or that I probably would have found otherwise, is sufficient to set aside the verdict, then jury trials may well be dispensed with; for in such a case to differ from the Court upon a proposition of fact is to annul the verdict. This is not the rule. The verdict of the jury, when fairly attained, is entitled to some weight, even though it may not be such as the judge would have found, and it must be something more than a doubt that will justify the court in disturbing it. I find no warrant in the cases I have examined for saying that a fair construction of the testimony in this case does not sustain the finding of the jury."

THE following are the Mexican grants covering a large portion of the county of Ventura: Simi, 119,000 acres; Conejo, 50,000; Guadalupe, 40,000; Calegua, 10,000; Las Posas, 28,000; Santa Clara Del Norte, 15,000; San Miguel, 7,000; Sespe, 25,000; ex-Mission, 75,000; Ojai, 15,000; Santa Ana, 25,000; San Miguelito, 10,000; Canada Larga, 8,000; El Rincon, 9,000; San Francisco, 8,000, and a small tract belonging to the Temescal grant.

THE shipments of bullion from Eureka last week amounted to 315,167 pounds.

A BOOT and shoe factory is flourishing in Redwood City.

THE Summit mine, Napa county, was last week sold for \$10,000.

THE Amador canal is nearly completed.

Reconnaissance—Exploring Made Easy.

Science and the march of civilization have sent the explorer to the remotest parts of the earth. And close in his footsteps go the geodist, the geologist and the topographer; and then before us is spread a faithful picture of the new country and its resources. In this, England took the lead—having mapped accurately her home domains, she then covers all India with a net-work of triangles which challenges at once the wonder and admiration of the scientific world. And few are the nations who have not already accomplished much in the same direction.

Whether the object be to pioneer a road across the Alps, the Apennines or our own Sierras, or to connect sea with sea or ocean with ocean by canal, the same knowledge of the general principles of the earth's topography is indispensable. And this knowledge should be most accurate—for to a cursory glance of even the most intelligent, hills and valleys show nothing of order or system in their arrangement, but appear to be confusion confounded. Yet a closer scrutiny reveals a wonderful symmetry in their forms and positions. A symmetry which at once declares them the effects of natural laws—which are as simple in theory, and uniform in action as they are useful in practice.

Hills are most generally disposed in chains or ridges, though occasionally collected in groups and at other times detached or isolated. The chains usually consist of several ranges parallel in the main to the back-bone of the chain and often sending forth branches or spurs in transverse directions. At times, however, they are merely the slopes of a table land in which their summits merge. A marked exception to this though exists in our coast range of mountains; here we do not find one single continuous ridge or system of continuous parallel ridges bordering the Pacific, but we see it made up of a system of parallel ranges which appear to be distributed *en echelon*, and overlap towards the north-west in an ascending order from south to north. This is characteristic of the California coast range of mountains; and is visible on a good topographical map—the general direction of the small parallel ridges being north-west and south-east.

It is generally true if a principal ridge is met by two secondary ridges at the same point, the point of meeting is a maximum of height—and if a principal ridge is met by the sources of two water-courses at the same point then that point is a minimum of height; but, if it is met by a secondary ridge and water-course at the same point then nothing can be inferred.

The waters which have come down from the mountain tops from time immemorial have adopted in their descent the lines of greatest slope. And in coming down the slopes of a range of hills they form principal valleys whose directions are perpendicular to the crest of the ridge when it is horizontal, but when it is inclined, share its general inclination. These streams thus divide the chain or range into ridges which have the same general directions as themselves. And the feet of two of these opposite slopes which enclose a valley are generally parallel in all their windings, a projecting point of one corresponding to a receding cavity in the other. This symmetry is however occasionally replaced by alternate expansions and contractions.

The main ridge is cut down at the heads of these streams into gaps or passes. And since the heads of these streams are at the lowest gaps in the ridge we hence have but to follow up the main water courses to find the lowest passes or gaps in a range of mountains. But as the ascent of a river to its source is often extremely difficult, if not altogether impracticable, on account of marshes, hogs, falls, etc., hence, in searching for the lowest pass in a main ridge, it will often be found most expeditious to ascend some tall neighboring peak and from thence follow the main ridge—determining as we go, our successive elevations by a level or barometer—until we find the lowest gap or pass.

Each peak has its ridges radiating from its summit and widening (though tortuously it may be) to its base, and from hence the rule when scaling a mountain peak, get on and follow a ridge. If we ignore this idea and strike a hee-line for the summit, we find to our sore chagrin that "the nearest way around is not always the shortest way through."

The explorer should be able to read topographical maps; so well conversant with them that when he looks upon one it will not appear to him, as it does to the inexperienced eye, a mere plane surface of paper and curved lines, but up before his mind will rise the topography of the region, in bold relief—Yes, a model in relief of the country with its gentle slopes and steep declivities, its hills, valleys, mountains, plains and water courses.

But as the contours of only comparatively small portions of the lands of the earth have been mapped, it becomes all important that the explorer be able to read the tale which the water-courses tell of the topography of the country. If two water-courses flow in opposite directions from a point, it indicates that there is a ridge of hills separating the two streams, and that this is the lowest point of the dividing ridge. And if the water-courses of a region are found to all diverge from a certain point, then it shows that is the highest point of that region; but if they all converge to one point, then this is the lowest point of that region. Yet, if two water

courses flow in the same general direction, and parallel to each other, it merely indicates a general inclination of the dividing ridge in the same direction. Still, if any of their tributaries approach each other at their sources, the point of their nearest approach is the lowest point of the separating ridge. And if two streams have been flowing in the same parallel directions, and at a certain point diverge from each other, that spot is the lowest point on the ridge between them. But if we have two streams in the main parallel in their course, but flowing in opposite directions, there is nothing to indicate the direction of the inclination of the ridge separating them, if any exists; and the lowest point in this dividing ridge will be shown by the approach of the sources of their tributaries to each other or by the principal streams approaching each other at any point.

To readily find one's position is another essential point in reconnoitering. If provided with azimuth compass, pocket chronometer and sextant, positions can not only be readily determined but also a sketch made of the sections of country traversed. But when none of these facilities offer there are other approximate means of orienting one's self and taking bearings when the sky is overcast. Thus in sparse forests the weather side, generally the north in the northern hemisphere and the south in the southern, is known by the bark of the trees on that side being coarser and thicker, and more moss covered than the other sides. In trees cut down the tops of the stumps show the circles narrower together, so that the heart lies

BRIZEE'S IMPROVED FAUCET.

nearest this side. Boulders are often grown over with moss on the weather side, the ground under the same being especially damp. And hills are covered on the north side with grass and moss, but not on the south side, because the little insects keep that clear so that their larvae may bask in sunshine.

It has been suggested that panoramic views or plans of a country might be obtained by sailing over it in a balloon. Yet however convenient this might be in determining the relative amounts of land and water and the meanderings of streams, it would clearly be of little or no utility in sketching the general topography of a country, since we know that the undulations of the surface of the earth do not show from a balloon.

The striking contrast of our Atlantic and Pacific coast lines is patent to the most superficial observation. While on our eastern coast we see numerous bays and rivers reaching far inland and producing a broken and serrated coast line, on our western coast we find a coast line remarkable for its regularity and continuity, indented by but few large bays and rivers. This great difference is due to the geological structure of the regions. It is true that the mountain ranges run parallel with the coast on both sides of the continent, yet on the Atlantic side the mountains are separated from the seashore by a broad slope of sedimentary strata in which the long bays have been excavated and the rivers found their clear, winding ways to the sea; while on the Pacific side the mountains rise directly from the ocean like huge walls and are rarely flanked by broad low slopes towards the sea. These mountains by their hardness and continuity prevent the formation of rivulets.

To the hydrographer a knowledge of the general principles of the earth's topography is also invaluable—enabling him to better judge of the general topography of the sea bottom adjacent to the coast. "Off our western coast, at irregular distances, appears to be a range of submarine mountains."

QUICKSILVER IN UTAH.—They talk about having discovered a "ledge" of cinnabar in Camp Floyd District, Utah, which assays from 20 to 75 per cent. in quicksilver. Utah does not want California to be ahead of her in mining matters, but 75 per cent. cinnabar ore even beats this State and in fact most any country in the world. Perhaps if we discount 70 per cent. the report may be true, but even that is perhaps doubtful. Utah assays are generally pretty heavy ones.

Mechanics' Institute.

The Nominating Committee of the Mechanics' Institute have nominated the following gentlemen as Trustees for the coming year: A. S. Hallidie, A. R. Wells, R. B. Woodward, W. P. Stout, Henry L. Davis, George Spaulding and James Spiers. The building in which the approaching exhibition is to be held is rapidly going up. The floor is laid and the heavy timbers and large lumber necessary are on the way from up north. The Institute do not intend this year to give diplomas or prizes of any kind; but if the representatives of any one class of articles desire a report made on exhibits in that class, the report will be made by a special committee.

The reason why the Institute has concluded to dispense with the diploma and premium system, is that it gave great trouble, consumed a large amount of time, and in the end gave cause for much dissatisfaction among the exhibitors. It is, of course, impossible to please all, and the Trustees think the better way will be to allow articles to stand on their own merits without any official recognition by the Institute as to what is best or worst in any particular class. Subscriptions are now being solicited to aid in defraying the expenses of constructing the pavilion. The contract for constructing the building was let for the sum of \$69,600; but it is estimated that the structure will cost upwards of \$95,000 before ready

Permanent Faucet for Beer Casks.

Whether "Local Option" prevails generally in this State or not, as it does now in several localities, people will drink beer. If it does prevail, more people will have their kegs of beer in their houses than do so at present, and the community generally will therefore be more interested in an improvement which is more for the benefit of brewers than any other class. The improvement to which we refer is the invention of John Brizee of Alameda county, recently patented through the Scientific Press Patent Agency, and is intended as a permanent faucet for beer and other casks which contain liquid under pressure. Its object is to permit the contents being drawn without the trouble of driving a faucet into the cask by driving out the plug or bung at the risk of losing the liquid.

The arrangement is very simple and effective, as the following description and accompanying engraving will show. Referring to Fig. 2, A, represents a casting which is provided with a short projecting tube at one side. This tube is provided with screw threads so that it can be screwed down into a hole in the head of the barrel, leaving the casting, A, fitting closely down against the outside of the head. This casting, A, is not as high as the chimes of the barrel or cask, so that it will not interfere with the standing of the cask on end. A conical hole passes horizontally through this casting, parallel with the head of the cask, and in this hole is placed a tapering plug similar to an ordinary tap plug, secured by a nut at its small end.

In the outer face of the casting, A, is a hole with interior screw threads. The hole is in line with the hole through the short tube which screws into the barrel head on the opposite side of the casting. The tapering plug passes directly across through the casting between the two holes, and is itself provided with a hole which will form a direct communication with the interior of the barrel when the plug is turned so as to bring the hole in line; but when the plug is turned out of this position the communication is closed in the same manner that an ordinary faucet is operated.

A bent tube, C, has one end provided with screw threads so that it can be screwed into the hole in the casting, and through which the liquor will flow. This tube is removable so that it will not be in the way when the barrel is turned on end. The tap can be turned by a lever handle, D, which is detachable. This tap is provided with a countersunk triangular end, over which a small triangular wrench, E, is fitted, in order to turn the tap. B is a cover hinged to one corner of the casting, so that it can be shut down over its upper face and end, when the tube, C, and wrench, D, are removed, and thus protect the openings from becoming filled with dirt. This is shown in Fig. 3, the cover being closed over the hole in the casting.

Fig. 1 shows the faucet when liquid is being drawn, the lever, D, being down. Fig. 2 shows the faucet closed, the lever, D, being up. Fig. 3 shows the arrangement when closed, the barrel not being in use. The invention provides a permanent faucet which only needs the tube, C, to be screwed into its place and the tapering plug to be turned by the lever, D, to draw the liquid, thus avoiding the trouble of driving in a faucet every time the barrel is tapped.

SAGACITY OF BIRDS.—Certain facts render it probable that birds, in some manner, become aware of cholera infection in the air. Recent European journals state that at Munich, where several cases of cholera have occurred, the rooks and crows, which flew about the steeples and through the trees of the public promenades, have all emigrated; and the same thing happened during the cholera seasons of 1836 and 1854. According to Sir Samuel W. Baker, the same phenomenon occurred at Manritius, where the martins, which exist in immense numbers the year round, wholly disappeared during the prevalence of the cholera.

The mines at Moore's Flat, Nevada county, are mostly idle on account of the difficulties about water. The miners there want water for eight cents an inch, and the owner of the ditch wants twelve and one-half cents an inch for the water.

THE BULLION.—The long-pending suit in the Supreme Court, between the Bullion and the 420 Mining Company, has been decided in favor of the Bullion, giving it a clear and now undisputed title to that portion of its claim.

The Diamond Drill has bored a hole 1,040 feet deep in Canada, and at Midlothian a bore hole made by one of these machines is 1,142 feet deep and it is 4 feet 8 inches in hard granite at the bottom.

The ore vein on the 1,500-ft. level of the Consolidated Virginia mine is much wider than it was on the level above, as well as being richer ore, promising a body 100 feet in width.

The new hoisting-works building on the Ledy Bryan mine, on the Comstock, is nearly completed, and the engines will soon be ready to start up.

The mills are all running up to their full capacity on Crown Point ore, and the future of that mine looks very prosperous.

The ore shipments for the week, says the *Battle Mountain Measure for Measure*, have been 100,855 pounds of copper ore, destined for Liverpool, and 170,700 pounds of antimony ore, consigned to A. M. Star, of San Francisco.

PLACER mining is being carried on very actively at Silver City, Nevada. Large parties of men are engaged in sluicing in both the eastern portion of the town and also in a cañon situated a short distance west of the same. They are meeting with good success.

The Virginia and Truckee Railroad Company have made arrangements to lay their track with steel rails, all the way from Virginia to Empire. Three hundred tons of steel rails have already been shipped from Liverpool for this purpose, and two hundred from Pittsburgh, Pa.

There are eleven woolen mills on the Pacific coast—eight in California and three in Oregon. They have in the aggregate 28,840 spindles and 232 broad looms.

Of the thousands of mines owned in Utah, but one is owned and controlled exclusively by Mormons, and of all the smelters and mills in the Territory, only one is owned by Mormons.

COMPROMISED.—The suit of the Constitution Mining Company vs. the Morning Star, of Cornucopia district, has been compromised. Both mines are to be consolidated.

The Casket mine, Tybo district, the property of J. D. Page, has been bonded by Mr. McGee, of Eureka in the sum of \$20,000.

There are six furnaces working ores in Eureka now, and three more will soon start.

A post office has been established at Pine Flat.

The Holcomb Valley Mines.

The Los Angeles Herald publishes the following facts, gleaned from a conversation with Mr. Goldsworthy, Deputy U. S. Surveyor, who has recently returned from the Holcomb valley mines:

Holcomb valley is located in the Coast Range mountains, about 120 miles northeast of this place, and 65 miles by wagon road or 36 by bridge-path from San Bernardino. It is a small valley, about 8,700 feet above the sea level, varying from one and a half to one and three-quarters miles in width, by about four in length. The entire area included in this valley does not probably exceed 10 square miles. Undersliding this surface are the placer deposits, and in the adjacent hills are found the ledges of ore-bearing rock. There is abundance of pine timber and a good supply of water for milling and sluicing purposes. The mines are accessible by a good wagon road running through the mountains.

The Quartz Mines

Are in a granite formation, the veins varying from six inches to six feet in width, comprising veins bearing free gold and iron pyrites, with slight tints of lead, copper and base metals. As yet, mining in this section may be said to be at its very commencement. Some of the mines were worked 10 or 15 years ago, but were long since abandoned, and it is only within the last year that work has been resumed.

The Holcomb Valley Company

Control the principal quartz mines of this section, under the supervision of Capt. John Haley. They alone have sufficient machinery for the successful prosecution of the work at present. This company has a quartz mill which reduces about 15 tons of ore per day. They have a shaft sunk to the depth of 170 feet, all the way through ore, with side drifts running to the westward from the shaft and covering a block of ore 170 feet long by 80 feet in height. The ledge averages from 18 inches to two feet in thickness, and pays in the neighborhood of \$40 to the ton.

A Sawmill

Is in course of construction by the company, and during the summer another 20-stamp mill will be built for the reduction of ore. Under the efficient management of Superintendent Haley, the affairs of this company seem to be in a most prosperous condition.

The Ozier Ledge.

Owned by Judge Widney, Mr. Ward and Mrs. Ozier, is the next in prominence. It has not yet been worked (the survey having but recently been completed), but it gives great promise of containing valuable ore, and is in the hands of those who will push it to a speedy development.

The Green Lead.

Worked by Mr. Garvey, is also said to show some fine specimens, and work is carried on upon it with vigor.

The Carter and Hub Mines

Are also said to promise excellent results, and they are worked by the owners in a most enterprising manner. Another 20-stamp mill will be built upon these premises by the proprietors.

Other Ledges.

A large number of outside leads, worked by various individual miners and mining companies have been sunk from three to twenty feet deep, and all show first-rate prospects. Some of these same mines, when worked in former times, had as much as \$15,000 to \$20,000 taken from them by assays—a very rude form of securing the metal from the ore. It is said that what has been done can be done again, and if these mines, worked by such inefficient means, yielded so well fifteen years ago, it is beyond a peradventure now that they can be made to pay handsomely. In

The Placer Mines

Underlying the whole valley there is supposed to be a gold-bearing stratum of gravel from six inches to three feet in thickness. Only the outer edges of the basin have been worked, where the deposit, lying near the surface, is most accessible. These more shallow mines were also worked in former times, together with the quartz mines, but also were abandoned by the men engaged upon them for more alluring prospects in the upper country. In some places excavations have been made to a depth of twenty-five feet, when bed-rock is found. The pay-dirt yields from one-half a cent to five and six cents per pan.

The Center of the Basin

Is still virgin soil, having never been worked on account of the great depth to the bed-rock, probably 125 feet, together with the lack of sufficient machinery to pump the water from the excavation. The probabilities are that the richest deposits will here be found. Judging from the deposits around the rim of the basin, there is without doubt untold wealth waiting for those who have the means and pluck to dig through the one hundred feet or more of soil, and take it from its lodging place upon the bed rock.

The Lazarder Company

Have sunk a main below the first hard-pan and have found a second stratum yielding gold-bearing dirt equal to that above. This mine is now worked by Lazarder & Brothers with success.

The Resources of the Valley

Are as yet almost unknown, having been pro-

pected in only the most accessible portions, and doubtless the richest discoveries are yet to be made.

Sufficient Water

For sluicing purposes is pumped from the mines as they are dug. In every respect there are ample facilities for developing the mines in their utmost capacity. A lack of proper machinery is the most noticeable want of the region. The abundant supply of wood and water, together with the unlimited amount of soil yet unprospected and the cheapness of machinery sufficient to carry on the work, offer

Excellent Opportunities

For miners to try their fortunes in Holcomb valley. About one hundred miners passed the winter in the valley, and since the opening of the season others have flocked there from other sections, so that there are probably 150 men now at work in the mines, and still they come. The snow is well cleared away, so that no difficulty is experienced by the miners from that source.

A New Town

Has been laid out in the eastern end of the valley. One store is already in operation, and a number of houses are in course of erection. Town lots are finding quick ready sale. There are at present some accommodations for travelers here, but they are limited, and there is a good opening for some enterprising man to start a boarding house.

A Great Rush

Will doubtless be made for this section during the coming season as its resources become better known. We shall take every opportunity to keep our readers fully posted in regard to any new developments which may be made. Meanwhile, we can but wish the best of success to the industrious gold hunters in Holcomb valley.

NEW ZEALAND MINES.—Ten years elapsed after the gold appeared in New South Wales and Victoria before it burst forth in its glory upon New Zealand. Some small fields were known before, but the year 1860 gave but an export of 4,538 ounces. The year after, the amount was 194,234 ounces; in 1862, 40,862 ounces, and in 1863, 621,450 ounces, valued at £2,431,723. After this famous rush to Otago, the yield fell. The export for 1864 was 480,174 ounces; for 1865, 574,574 ounces. But 1866 gave the summit of prosperity—735,376 ounces, or £2,444,517. Fortunate as Auckland was in 1873, the export of the whole period preceding 1871 realized only £1,005,238; while Nelson had raised £4,018,404. Westland, £5,812,187, and Otago £10,588,000. The total amount exported up to 1873 was valued at £26,816,323. The distribution of gold is far greater in the south island than in the north. With the latter it is confined to one province out of four, Auckland, and to but few places there. The south island has diggings in every province. Wellington offers £2,000 for the discovery of gold fields. The gold exported for the year ending June 30, 1873, was 447,759 ounces, valued at £1,732,687. Besides gold, the mineral wealth of the colony is not great. Silver, though known, has not been found in paying quantities. It is found with gold in the iron sands of Westland shores. Tin, seen at Tapano and Shortland, may be valuable some time; for, though recognized for many years in Australia, it has only just begun to be worked there. Platinum sand exists on the coast of Southland and Westland. Chrome iron ore is in such quantities at Dun Mountain, Nelson, as to have an excellent prospect of being a paying export. Chrome iron is also found at Milford Haven. Iron of a rich quality can be procured from large boulders of iron stone. The Taranaki iron sand has long been known and valued, though the difficulty of rescuing it on that stormy coast for many years prevented persons undertaking the work. Copper once promised well. Barrier Island was spoken of as a second Burra Burra. Paying lodes may eventually be found there at Kawan, Coromandel, etc. Tin is found in the Buller. Coal is being worked at Greymouth, on the west coast. That of a tertiary kind at Port Chalmers, Malvern Hills, Auckland, and many parts of the interior of Otago, Nelson and Canterbury will be utilized. Raglan and Westport are turning out good coal. The Bay of Islands seam is thirteen feet thick.

NEW SMELTING WORKS.—The Boulder county (Col.) News states that Gold Hill is at last going to have a home market for the valuable ores its mines are contributing to the annual production of Colorado's wealth. Mr. F. A. Hunt has purchased Horton's place at the junction of Boulder and Four Mile creeks, where he will at once proceed to erect ore concentrating works. The News says "his process is by 'wet concentration,' and the most approved machinery is provided, both for crushing and separating." In regard to Boyd's Smelting Works, in Boulder, the News says: No more welcome news could be given to our readers than the announcement we are now able to make, that the work of erection of the smelting works began the first of this week, in earnest, and will be energetically pushed to completion, it is said, in 60 days; but making allowance for the delay that usually attends such enterprises, it is not unreasonable to believe that in 90 days the work of smelting ores will have been begun in the town of Boulder. All the machinery—eight car loads—has arrived, in charge of Mr. Boyd, who is on the ground, superintending the erection. As the material is all on hand, no more disheartening delay is apprehended.

Coal Mines at Coos Bay.

A correspondent of the Call writes from Eureka, Humboldt Bay, as follows:

The Newport coal mine is owned by Flanagan & Mann, of San Francisco, who must have expended an immense amount of money to open the mine and put it in its present working trim. Few mines are worked so systematically; everything, no matter how trifling, is managed with the greatest regularity. The main tunnel is in over 1,800 feet, and the chambers occupied by each miner are about 20 feet square; in quartz mining it would be called stoping out. The style of mining resembles quartz mining very much—timbering, filling in and cutting out the face of the drift are the same—this only difference being that the rock is black instead of white, and the angle of the vein not so great. The miners are paid by the ton, and often make much more than wages, and even so high as \$100 per week, owing to good work and the increase of the vein. Each miner, after filling his car, labels it with his number; it is then attached to the train, which runs out on an incline, and in charge of the brakeman to the scales, over which each car passes, and is weighed by a receiver, who enters on a bulletin board the weight and the miner's number, so that on quitting work each man, by referring to the board, knows how much he has made. The coal after being weighed, is dumped into the bunkers, which are capable of holding 500 tons. At the bottom of each bunker a lever lifts a slide through which the coal drops into a train of cars backed up by the steam locomotive.

A CHAPTER OF ACCIDENTS.—William Cook, of this place, was quite severely hurt on Tuesday last, while at work in his hydraulic claim at Sport Hill. Cook was standing at the pipe, close to the bank, when a cave occurred. A rock struck him on the head, just back of the ear, cutting an ugly gash and contusing the bone considerably. Pleaded to learn that no serious results will ensue from the accident. Wednesday last a man named Daniel Keyes was terribly injured while at work in the San Bruno mine, at Mosquito Gulch. A large timber being hoisted up into the stope, caught, and Keyes ascended the ladder to disengage it. Subsequently, the timber having been raised several feet higher, the rope attached to it slipped off and it fell, striking Keyes a glancing blow, tearing his flesh from the side of his face, cutting and bruising his shoulder and side, and knocking him down into the level some fifteen feet below. His escape from instant death was miraculous. He will probably recover. Wednesday a Frenchman, named Barrot, had one of his arms broken in two places and four of his ribs fractured by being run over by a wagon. He attempted to jump from the vehicle to the top of the bank by the road side, but missed his footing, fell back, and one of the wheels passed over him. Dr. De Chesne was called, and the broken bones set, and the injured man is getting along as well as could be expected with an anatomy so badly smashed. The accident occurred near Rich Gulch Flat. —*Calaveras Chronicle, 16th instant.*

A CASE OF LEAD POISONING.—A miner named Anderson, living near Cement hill, has been afflicted with a derangement of the stomach and other digestive organs for a year or more, without receiving the expected relief from medical treatment. Suspecting that this spring-water which he had been using might be the cause of his troubles, he brought two samples to town for analysis, stating that the water of that spring had been considered unwholesome by those who had used it before he came there, and that it did not form the usual suds in washing, and that he had attempted to cook some split-peas in it, but failed. Upon being tested with nitrate of silver, a white, cloudy precipitate was observed, indicating the presence of chlorides. Other tests were applied, without remarkable results, until a given portion evaporated to dryness, when a residue was formed, equal in weight to eight grains to the gallon. Upon further examination the residuum was found to contain a large proportion of lead. A second analysis was made, with similar results, indicating lead in solution in sufficient quantity to produce serious symptoms of lead-poisoning. Other springs about Cement hill have long been suspected of containing poisonous waters, and have been tested for arsenic, without any definite result. Possibly if those waters were tested for lead, the colic and other painful symptoms that they cause might be easily explained. —*Nevada Transcript.*

S. FOSSELLI, an Italian, has invented a new method for exploding any mine or torpedo without electricity, the use of which agent he considers expensive, uncertain and often dangerous. He states that a torpedo, at any distance whatever, can be placed in immediate communication with a hydraulic pump by means of a small hollow, metallic tube, .08 in. in diameter, the tube being bare or coated according to the locality in which it is laid. The apparatus is simple. In a hermetically sealed case attached to the top of the torpedo, a hammer with spring action similar to that of an ordinary musket-lock, is placed and maintained in the position of "full cock" by a catch; against this catch rests a small hydraulic ram which communicates through the side of the case with the hollow tube. When the tube is filled with water, one or two strokes of this pump are sufficient to free the catch and effect the explosion. Air can be used in the tube instead of water.

Coal Cutting Machinery.

At the outset, it is apparent that if mechanical coal-cutters could be extensively and successfully employed, several advantages would be gained besides supplanting the man. Not only would strikes be at an end, but ventilation improved, and the depth of mining probably increased, since most of the difficulties caused by the limit of human endurance under exhausting exertion would be at once overcome. Collateral benefits of several kinds, particularly the disuse of gunpowder to at least a large amount, would follow; and on this account the question of the possibility of their adoption becomes highly important. Can mechanism of any kind, whether partly or wholly employed in coal mines, or can improvements in applied mechanism, be made to supersede the labor of man?

In thick seams like those of Staffordshire, in ten yard or even ten feet seams of coal, there is plainly no serious obstacle to the use of coal-cutting machines. You have only to cut and bring down, and deliver at the pit's mouth. But in thin seams and in the innermost passages of long-worked pits the case is very different. Any one who has actually seen a hewer at work in the most awkward places in thin seams, and no other person, will at once understand the difficulties to be overcome. A hewer in the worst "faces" of coal-getting must squat and twist and contort himself like a posture-master, and do so for some hours at a time. This adaptation the human body is capable of affording and enduring, and that most wonderful vital machine, the human arm and hand, can so twist and turn and harmonize itself to natural necessities as to show in this very circumstance its immeasurable superiority to any mechanism which the mind of man has conceived. Watch, for instance, a northern hewer making his "jud" and his "jeukin" in the coal seam, and then turning and squatting, and sidling and squeezing, and gasping and sweating, and picking and poking with perfect bodily adaptation to mining exigencies, and you will form such a conception of the peculiarities of the work as will very much modify your expectations of a mechanical substitute for the grumbling and perspiring hewer. —*Coal Trade Journal.*

HIDDEN TREASURE MINING DISTRICT.—A correspondent of the Tulare Times writes as follows about the Hidden Treasure district:

Knowing that a great many are expecting to hear the latest news from the new mines through your most valuable paper, I therefore give the following from this district: People wishing to visit the rich mines in this district will take the old Kaweah trail, up the South Kaweah river. Ten miles above Mr. Blossom's they will come to the Topsy lead, or the one nearest the valley yet discovered. Near the west side of this mineral belt, the main course of the leads are from the southeast to the northwest. The mineral belt is about ten miles wide. There have been seventeen mineral bearing leads or veins found in this district. Up to the present time the average width of the leads is about fifteen feet. As far as they have been tested the most of them are paying leads. There have been found in the district gold, silver, copper, zinc, galena, iron and tin. The dark brown zinc blende is very rich in silver, and contains some gold; this district is abundantly supplied with that character of ore. Then we have the glance-silver, red and brittle silver ores, glance-copper, silicate of copper, and the red and gray copper ores. The snow has disappeared so that prospecting can be done from the May Flower lead for six miles in width down the river to the Topsy lead. There have been recently fifteen rich leads discovered between these two points. We will have more thorough prospectors soon, we have no doubt, and they will be well paid for their trouble. We have the thriving town of Cedar City. Buildings are going up as they always do in mining towns—that is, in a hurry. We expect to have a saw mill running in two or three weeks. Several families expect to make Cedar City their home during the hot summer months. It will be only about fifteen miles from Cedar City to the principal mines in the Mineral King district, and over a very good trail. Those who are desirous of visiting Mineral King district will do well to come up the south fork of the Kaweah river, as they will pass through the Hidden Treasure district.

A SPECIMEN NEWSPAPER ITEM.—An enterprising citizen of Philadelphia has proposed to build, in time for use at the international celebration, a ship capable of carrying ten thousand passengers. It is to combine a steam railway, a race course, theater, shooting gallery; circus, and every imaginable modern attraction. He claims that his plan is complete, and has been approved by some of the ablest engineers. He proposes to moor it in the Delaware, and convey it at intervals to the different cities, ports, and watering-places of the continent. It will make about six miles an hour, and will be three or four times larger than the Great Eastern.

For the last five or six years the Society of Industrial Sciences at Lyons have been carefully investigating the capabilities of the common broom (*Sarothamnus scoparius*) as a textile plant. From a recent report we learn that the fiber makes an excellent coarse cloth, suitable for domestic purposes.

CINNABAR prospectors continue to flock to Lake county.

THE MINES OF TASMANIA.—Gold is not plentiful, though licenses are regularly issued for its working, but at the high rate of £2 a year. Coal ought, one would imagine, to be of more commercial importance than it has been. But the fields are difficult of access. The bituminous product of the east coast cannot be made so available as is wished, owing to the approach being simply an open roadstead. The Mersey coal is easier reached, while that of Jerusalem and other inland fields is too far away from a port. Iron promises to be an important source of wealth. Mr. Gould calculated that 700,000 tons of hematite iron was easily obtainable at Ilfracombe, on the north coast. The ore is being worked by the Tasmanian Charcoal Company. A valuable lode of the same crops out in other parts near. The iron of the Severn and Forth will be of future value. Good specular iron may be wrought in the Dial range. Nodules of pyrites are found on the island of D'Entrecasteaux Channel. Red and brown hematite is known on the west bank of the Forth and on the Hellyer. Tin in rich lodes and sand is known at Mount Bischoff, forty miles from Table Cape. Lead ore is known at the Forth, is a seam one foot thick. Manganese and zinc are at Penguin creek, to the northwest. In the creek, also, were specimens of copper. Plumbago, in small quantities, is seen on the Norfolk plains, and crystals of oxide of titanium are picked up in the river Forth. Mr. Gould thought that the Gordon river limestones would prove highly metalliferous. When the coal of the country can be utilized in the smelting of iron ore, Tasmania will be famous as a mining country. The Flinders Island topazes are valuable.

JUST PUBLISHED.

Froiseth's New Sectional, Topographical and Mineral MAP OF UTAH.

SIZE, 40 BY 56 INCHES; SCALE, 8 MILES TO AN INCH.

Handsomely engraved on stone, colored in counties, and mounted on cloth, showing the Counties, Towns, Rivers, Lakes, Railroads, Mines and Mining Districts throughout the Territory, and all GOVERNMENT SURVEYS made to date. Price, mounted, \$8; Pocket form, \$5.

—ALSO—

New Mining Map of Utah.

Showing the boundaries of the principal mining districts, some 30 in number, adjacent to Salt Lake City. Price, pocket form, \$2.50.

—ALSO—

Froiseth's New Map of Little Cottonwood Mining District and Vicinity.

Showing the location of some 400 mines and tunnel sites, together with the mines surveyed for U. S. Patent. Price \$3. For sale and mailed to any part of the globe, on receipt of price, by A. L. BANCROFT & CO., A. ROMAN & CO., and LEONARD BROS. & MANSUR, San Francisco. 10v25-11

Diamond Drill Co.

The undersigned, owners of LESCHOT'S PATENT for DIAMOND-POINTED DRILLS, now brought to the highest state of perfection, are prepared to fill orders for the IMPROVED PROSPECTING and TUNNELING DRILLS, with or without power, at short notice, and at reduced prices. Abundant testimony furnished of the great economy and successful working of numerous machines in operation in the quartz and gravel mines on this coast. Circulars forwarded, and full information given upon application.

GRAND INDUSTRIAL EXHIBITION,

To be held under the auspices of the

MECHANICS' INSTITUTE

OF SAN FRANCISCO, CALIFORNIA,

Opening on August 18th, 1874.

The Board of Managers herewith announce that a grand Industrial Fair will be held in the city of San Francisco for 30 days, opening on August 18, 1874. In view of the increasing commercial and manufacturing importance of San Francisco, its contiguity to and close connection with the various countries bordering on the Pacific, the managers have constructed a Pavilion having a floor area of 150,000 feet, and have invited to it all who are disposed to come and exhibit. All exhibitors will be placed on the same footing. Motive power will be furnished free.

The building will be open day and evening, and every facility will be extended to exhibitors and visitors. Application for space must be made without delay to the Secretary of the Board of Managers, 271 Post street, San Francisco, and all inquiries will be answered and information extended promptly.

No space can be secured unless applied for before the 20th of July next.
A. S. HALLIDIE, Pres.

Suits Against the Sutro Tunnel.

Complaints have been filed this week in the 15th District court by the mining companies on the Comstock lode against the Sutro Tunnel. The following companies have filed the complaints: Crown Point, Chollor Potosi, Gould & Curry, Imperial, Overmen, Ophir, Savage, Hale & Norcross, California, White & Murphy, Best & Belcher, Alpha, Bacon, Gold Hill Quartz, Confidence, Empire, Yellow Jacket and Belcher. The suits are commenced against the Sutro Tunnel Co., Adolph Sutro, Henry K. Mitchell, Louis Janin, Jr., and William M. Stuart, to rescind the agreement between the company and the mines; to release the mines from all lien by the defendants, and to join them from setting up any claim or title upon said mine.

Each complaint goes on to say that from the 4th day of February, 1865, said Sutro conceived the project of running a tunnel from the foot hills of the Carson river valley into the Comstock, for the purpose of discovery and development of the bodies of minerals, which by the laws, customs and usages then and ever since prevailing in the State of Nevada, would on such discovery become the property of Sutro and associates, and for the purpose of inducing the owners on the Comstock and other lodes to avail themselves of the advantage of said tunnel at prices to be agreed upon, and for other purposes.

That pursuant to said project Sutro procured the passage by the Nevada Legislature of an act granting the right of way, and authorizing Sutro and his associates to construct a mining and draining tunnel, approved February 4th, 1865.

That after the passage of the act, and before a blank day 1866, Sutro and other individual defendants, and D. E. Avery, deceased, associated themselves together, and in accordance with the terms of the aforesaid law. That on and before the last named day the mine of plaintiff was affected by the flow of water therein and was in need of better ventilation, and was supplied with hoisting works of simple character and quite limited power, and said Sutro and his associates represented to plaintiff that they could complete said tunnel within the time named in the said act, to-wit: eight years from the 4th of February, 1865, and in accordance with the other terms and conditions thereof; and that the mine of plaintiff would be drained and ventilated, and the labor and expense of plaintiff's business be greatly reduced, and the plaintiff and the said individual defendants and the said deceased Avery made a written agreement in relation to the premises, a copy of which is annexed to the complaint.

And the plaintiff further avers that on blank day of 1867, at the request of individual defendants, the plaintiff further extended the time in Articles 1st, 3d, 4th and 5th, so that it should read August, 1868, instead of August, 1867.

And plaintiff avers that it hath in all promises on its part kept them, but that said defendants did not keep the promises made in said agreement on their part; that the defendant did not commence this work on or before August, 1865, and did not prosecute the work with reasonable energy or vigor, nor were the tunnels and drifts mentioned now excavated or completed, or put in condition for use, in accordance with the Act, or with the agreement, by which they agreed to simultaneously sink three shafts on the line of the tunnel, nor has the said work been performed continuously or without interruption, although no unavoidable accident has happened in relation thereto; that on the contrary the little work that has been done has been done feebly, with great intervals of delay.

And plaintiff further avers that there has not been subscribed in good faith, or at all by responsible persons, any sum nearly so large as \$3,000,000 for the said work, nor any sum sufficient to complete said work; and that on the first of August, 1868, there was not expended \$400,000, or any other considerable sum, nor has there been expended after said fiscal year \$200,000 annually, or any sum approximating that amount. And the said defendants have not furnished any statement whatever, of the expenditures on the work, during all or any of said years. The completion of the work has been immeasurably delayed, and without just cause.

And plaintiff further avers that the agreement declared that if work was not commenced before August 1st, 1867 (extended to 1868), and the sum of \$3,000,000 subscribed and 10 per cent. paid in, and after commencing should fail to expend the first year or any year the sums agreed, the said agreement should, at the option of the plaintiff, cease and thereafter be of no effect.

And the plaintiff avers that before November 29th, 1869, the plaintiff exercised its option that the agreement should be of no effect, and that defendants had notice thereof, and the plaintiff, to the knowledge of the individual defendants, declared and treated said agreement as rescinded, and the plaintiff does now again exercise its option and forbids the prosecution of the work under said agreement.

And the plaintiff avers that on November 29th, 1869, the defendant became a body politic, and organized as such under the laws of California, and acquired all the rights and franchises of the now individual defendants.

And the plaintiff avers that shortly after the said incorporation, the individual defendants

made a legal transfer of all their rights, franchises and property owned under the Act of the Nevada Legislature.

That the defendant has failed to perform its agreement, and that all the breaches of the agreement set forth have been made; the time fixed by the act of the Legislature—eight years—for the completion of the work, has passed; that not one-tenth of the work has been done, nor will the work be completed in eight years more. Plaintiff avers that in said agreement, time was made the essence of the contract, and that after the expiration of said eight years, plaintiff did declare and announce that said agreement had ceased and become of no effect, and plaintiff again exercises its option that the agreement shall cease, and forbids any more work to be done under said agreement.

Plaintiff further avers that on the failure of defendants and of said Avery to perform their agreement, and on becoming satisfied of their inability to perform the remaining portions thereof, plaintiff prosecuted its work in its mine without reference to defendants or said agreement, and by other means has secured the objects intended to be accomplished by said tunnel, and that by a great expenditure of money and labor it has got rid of said flood of water in its mine, and secured other means of drainage and ventilation, procured machinery for hoisting, and entered into contracts for transporting its supplies and ores, and that the works of plaintiff in said mine have long since reached a depth far below the level of the tunnel as contemplated by defendants.

The plaintiff avers that by reason of defendant's delay, and of said Avery's, in prosecuting said work, and their feeble and inefficient manner of conducting the same, other expedients have been planned and executed for working mines in the Comstock lode; that mills have been built at places more convenient than the mouth of said tunnel, a railroad constructed to carry ores from the mines to the mills, and that the conditions and surroundings of the mines have been materially changed since the agreement was made; and if the tunnel is hereafter completed, it will be of no use for any purpose whatever.

Plaintiff further avers that the work already done has been upon defendant's grounds, and is of no use to plaintiff, and has been almost entirely done since plaintiff rescinded the agreement.

Plaintiff further avers that defendant insists that it has the right to go on and perform said work under said agreement, and that the same shall be binding upon plaintiff and its mine, and that it shall have a lien upon the same as its security in the premises, and plaintiff declares that the agreement was made in triplicate, one copy being in possession of defendant, another in the custody of the plaintiff, and the third deposited by consent in said city and county; and that said agreement remaining uncancelled throws a cloud upon plaintiff's title, and obstructs any sale, lease or hypothecation that it may desire to make, and subjects plaintiff to danger of future litigation.

The plaintiff therefore prays that said agreement be adjudged to be rescinded; that the same be delivered up to be cancelled, and that the plaintiff hold its mine free, and discharged of any lien or claims under said agreement; that the defendant be directed to acknowledge and deliver a release of its alleged lien in the mine of plaintiff by reason of said agreement; that defendant be enjoined from setting up any lien or claim, to or upon said mine, and for such other relief as is meet in the premises.

The complaint is signed by Wilson & Wilson, attorneys for plaintiff, and R. S. Mesic, J. P. Hoge and S. M. Wilson, of counsel for plaintiff.

Treating Textile Products.

Some time ago we made an inquiry for a machine capable of treating ramie fiber so as to quickly and thoroughly place it in a marketable condition. We now receive a letter from Mr. Chas. F. Dennet, of Brighton, England, in which he claims that he is able to answer the demand for a machine which will really do all that is desirable for the grower, the merchant and the spinner, speedily economically and perfectly; producing the largest quantity of available fiber, without loss or injury, from the stems, thus bringing the crop from the hay and grass level up some sixty per cent. in value. Mr. Dennet has given ten years' time and much money to promote the introduction, growth and use of the rhea or ramie plant, considered only a nettle, *l'ortie de la Chine*—into America and European countries, and received for his valuable services in this direction the silver medal of France. He is certain, he says, that a new industry can be raised up in California, in the culture and manufacture of the ramie staple, which will add greatly to its present prosperity.

Mr. Dennet also sends us a description of his new machine for disintegrating, breaking, "scutching" or rendering supple ramie or rhea fiber, as well as flax, hemp, jute and all textile materials and vegetable matters generally, with or without rotting. We use the inventor's own words: Two grooved posts rubbing against each other, in a peculiar manner, cause the softening of the ramie, hemp, flax, or other material, at once removing the epidermis, wood, gum, gluten, etc., adhering to the matter.

The system of softening or rendering supple offers several great advantages over those hitherto adopted. First, in the lightness of

the working of the machine. One horse-power is sufficient. Second, consists in that the material rendered soft or supple suffers no waste, no deterioration, no breaking, no pulling, tangling or mixing, so that the return in the combing is greater than that of any of the textile materials softened by the means hitherto known; not a fiber is wasted, injured or lost.

As to the stripping and breaking, it is effected in nearly the same way as the softening. Thus, suppose the raw hemp coming from the setting, the handful or quantity introduced to the machine passes first to the rollers, which break and bruise the straw; it then undergoes the friction operation by the grooved apparatus (worked by a cone and go movement) and leaves by the second rollers almost entirely free from straw. Each machine comprises several arrangements of friction plates, and this number will vary, according to the nature of the textile material operated upon. In the center of each friction plate, when fixed or movable, and of the first or second kind, is made an opening to give passage to the textile material being treated. The very little wood still contained in the fibre is detached and a shake renders it perfectly clean. This applies equally to all textile materials. The time during which the batch of rhea or ramie, hemp, etc., undergoes its friction or manipulation by the apparatus, may be modified by changing the pinions according as the nature of the material requires more or less softening. If it may happen that the workman in charge of this machine does not make very regular batches, the defect is obviated by springs with which the apparatus is provided, and the provision is made that the rollers may be equal upon each batch however thick it may be.

Such is the newly invented machine without going into more particular, scientific and mechanical detail, and by the aid of which can be treated, with or without rotting, by changing parts of the same machine, every kind of vegetable fiber intended for spinning, for which it can be rendered suitable. The machine works speedily, does a good day's work with great economy in labor, affords a large return, and without causing loss of strength. It has been tried long enough by skilled and experienced men, and pronounced the thing *par excellence* for the ramie plant and the purposes for which it was designed; in short, says the inventor, it is the only machine that will take the raw material, turning it out in bulk per diem in a commercial condition, enhanced in value ready for the manufacturer, and any other process to follow.

By the aid of this new means of operating it has been demonstrated, it can be modified, transformed and appropriated for spinning the most varied raw textile materials; reducing, dividing and fining so as to draw therefrom the thin, delicate fibers intended for spinning for every denomination up to the finest.

PATENTS & INVENTIONS.

A Weekly List of U. S. Patents Issued to Pacific Coast Inventors.

[FROM OFFICIAL REPORTS FOR THE MINING AND SCIENTIFIC PRESS, DEWEY & CO., PUBLISHERS AND U. S. AND FOREIGN PATENT AGENTS.]

By Special Dispatch, Dated Washington, D. C., May 26, 1874.

FOR WEEK ENDING MAY 12, 1874.

BUILDING AND PAVING BRICK.—Bar Adler, S. F., Cal.

BROOM MACHINE.—Henry Anderson, S. F., Cal., and James F. Houghton, Sacramento, Cal.

REFINING BULLION.—Frederic H. Bouafeld, S. F., Cal.

BRACE SHOE.—Henry C. Deering, Hope Valley, Cal.

ANIMAL TRAP.—Augustus M. Gass, Campo, Cal.

CAP AND FAUCET FOR BEER CASKS.—John G. Schiffer, S. F., Cal.

WHEEL FOR VEHICLES.—Michael Mickelson, Ashland, Oregon.

TREADLE.—Edward Duffly and Robert Swarbrick, Oakland, Cal.

TRADE-MARK.

FLAVORING EXTRACTS OR SYRUPS.—McMillan & Keater, S. F., Cal.

"The patents are not ready for delivery by the Patent Office until some 14 days after the date of issue. Note.—Copies of U. S. and Foreign Patents furnished by Dewey & Co., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest time possible.

VICTORIA C. WOODHULL, the somewhat noted social agitator (reformer) is to lecture in Platt's Hall, Monday evening at 8 o'clock. Subject, "Reformation or Revolution, Which?" Of this lecture the Dubuque (Iowa) Herald says: "Victoria C. Woodhull is a woman of brains, of eloquence and elegance—like herself and nobody else—Victoria C. Woodhull to the core—bold and defiant in her theories, and unrelenting in declaring them. She has a perfect grace of oratory; every gesture and attitude is refined and eloquently expressive, and she sends forth her silver voiced sentences as though she had the power of a hurricane behind them."

SCIENTIFIC PRESS.—The attention of our readers is called to an interesting article on the Mining Interests of Northern Sierra, on the first page of this issue, from the SCIENTIFIC PRESS, San Francisco. This is the ablest, most instructive and influential Mining Journal published in the Great West, and should be liberally patronized by all our mining friends.—Mountain Messenger, April 25.

DEWEY & CO.

American & Foreign Patent Agents,

OFFICE, 338 MONTGOMERY STREET, S. F.

PATENTS obtained promptly; Oaths filed expeditiously; Patent reissues taken out; Assignments made and recorded in legal form; Copies of Patents and Assignments procured; Examinations of Patents made here and at Washington; Examinations made of Assignments recorded in Washington; Examinations ordered and reported by Telegraph; Rejected cases taken up and Patents obtained; Interferences prosecuted; Opinions rendered regarding the validity of Patents and Assignments; every legitimate branch of Patent Agency Business promptly and thoroughly conducted.

Our intimate knowledge of the various inventions of this coast, and long practice in patent business, enable us to abundantly satisfy our patrons; and our success and business are constantly increasing.

The shrewdest and most experienced Inventors are found among our most steadfast friends and patrons, who fully appreciate our advantages in bringing valuable inventions to the notice of the public through the columns of our widely circulated, first-class journals—thereby facilitating their introduction, sale and popularity.

Foreign Patents.

In addition to American Patents, we secure with the assistance of co-operative agents, claims in all foreign countries which grant Patents, including Great Britain, France, Belgium, Prussia, Austria, Victoria, Peru, Russia, Spain, British India, Saxony, British Columbia, Canada, Norway, Sweden, Mexico, Victoria, Brazil, Bavaria, Holland, Denmark, Italy, Portugal, Cuba, Roman States, Wurtemberg, New Zealand, New South Wales, Queensland, Tasmania, Brazil, New Grenada, Chile, Argentine Republic, AND EVERY COUNTRY IN THE WORLD where Patents are obtainable.

No models are required in European countries, but the drawings and specifications should be prepared with thoroughness, by able persons who are familiar with the requirements and changes of foreign patent laws—agents who are reliable and permanently established.

Our schedule prices for obtaining foreign patents, in all cases, will always be as low, and in some instances lower, than those of any other responsible agency.

We can and do get foreign patents for inventors in the Pacific States from two to six months (according to the location of the country sooner than any other agents.

Home Counsel.

Our long experience in obtaining patents for inventors on this Coast has familiarized us with the character of most of the inventions already patented; hence we are frequently able to save our patrons the cost of a fruitless application by pointing them to the same thing already covered by a patent. We are always free to advise applicants of any knowledge we have of previous applications which will interfere with their obtaining a patent.

We invite the acquaintance of all parties connected with inventions and patent right business, believing that the mutual conference of legitimate business and professional men is mutual gain. Parties in doubt in regard to their rights as assignees of patents, or purchasers of patented articles, can often receive advice of importance to them from a short call at our office.

Remittances of money, made by individual inventors to the Government, sometimes miscarried, and it has repeatedly happened that applicants have not only lost their money, but their inventions also, from this cause and consequent delay. We hold ourselves responsible for all fees entrusted to our agency. The principal portion of the patent business of this coast has been done, and is still being done, through our agency. We are familiar with, and have full records, of all former cases, and can more directly judge of the value and patentability of inventions discovered here than any other agents.

Situated so remote from the seat of government, delays are even more dangerous to the inventors of the Pacific Coast than to applicants in the Eastern States. Valuable patents may be lost by the extra time consumed in transmitting specifications from Eastern agencies back to this coast for the signature of the inventor.

Confidential.

We take great pains to preserve secrecy in all confidential matters, and applicants for patents can rest assured that their communications and business transactions will be held strictly confidential by us. Circulars free.

Engravings.

We have superior artists in our own office, and all facilities for producing fine and satisfactory illustrations of inventions and machinery, for newspaper, book, circular and other printed illustrations, and are always ready to assist patrons in bringing their valuable discoveries into practical and profitable use.

Examination solicited. 9v28-1y

THE SELDEN DIRECT-ACTING STEAM PUMP,

A. CARR, Manufacturer & Proprietor.

Patented

Aug. 2d, 1870.

Dec. 20th, 1870.

Combining simplicity and durability to a remarkable degree. Its parts are easy of access, and it is adapted to all purposes for which Steam Pumps are used.

As a Mining Pump it is Unsurpassed.

STEAM, GAS & WATER PIPE, BRASS WORK, STEAM & WATER GAUGES, FITTINGS, ETC.

CARR PATENT STEAM RADIATOR.

Send for Price List and Circulars. Address,

A. CARR,

10v28-1y 43 Courtland Street, New York.

STEAM ENGINES AND BOILERS

Of all sizes—from 2 to 60-Horse power. Also, Quartz Mills, Mining Pumps, Hoisting Machinery, Shafting, Iron Tanks, etc. For sale at the lowest prices by

J. HENDY, No. 32 Fremont Street.

oisoo, and 178 J St., Sacramento, Mr. Ly

THE KNOX & OSBORN QUICKSILVER FURNACE.

Fig. 1.—Cross Section of Furnace, Walls and Vapor-Way Arches.

Fig. 3.—Horizontal Section at Fire-Grate Level.

Fig. 2.—Cut Transversely from Fig. 1.

THIS FURNACE REDUCES CINNABAR, AND
WORKS CLOSER TO AN ASSAY

And at **LESS COST** per ton than any other furnace. It will work continuously Twelve to Twenty-four months without stopping.

No Man Has Ever Been Salivated

Or otherwise affected by the mercury about the furnace, either in operating it or making repairs. For full particulars, plans, etc., apply at

THE PACIFIC REDUCTION WORKS,

GUIDO KUSTEL, Superintendent, WILL PURCHASE

Gold and Silver Bearing Ores, Cuperiferous Silver Ores,

GOLD SULPHURETS, ETC., AT THE HIGHEST RATES,

OR WORK THE SAME FOR OWNERS' ACCOUNT.

The works will commence operations on or about the 1st of April. Sampling, Assaying of all kinds of Ore and working of small lots of ore in any desired way, will be promptly attended to and reliable results returned

mr21-16p

OFFICE—210 FRONT STREET, SAN FRANCISCO.

THE ONE-PLUNGER JIG,

Delivered on R. R. Car at Denver, Col., or St. Louis, Mo.

Separates in one and the same operation—1. galena and sulphide of silver; 2. pyrites or blende; 3. tailings, containing no valuable parts; or, 1. gold; 2. pyrites; 3. tailings (quartz, etc.) containing no valuable parts; or, 1. copper; 2. tailings, containing no valuable parts. The One-Plunger Jig can be combined with existing stamp-mills with highly important advantages, as after amalgamation it will recover completely all fine meta and all base ores and all mercury out of tailings. It concentrates all fine metal ores to such cleanliness that low grade ores can be shipped, after concentration, as first-class ores. Its feed and discharge are automatic. Its construction offers better guarantee against loss and repairs than any other apparatus in use. For particulars, apply to the inventor,

F. CAZIN

Number 23.

Work on Mining Claims.

Our mining friends, who have been worrying along for the past few weeks awaiting the action of Congress in reference to extending the time for the first annual expenditures on mining claims, may now rest easy, for the time has been extended. How long it has been extended is still rather uncertain, as the reports from Washington are so contradictory. The bill as first telegraphed to this coast represented the amendment as extending the time to June 10th, 1875. Another version of this bill, sent by the Washington correspondent of the *Bulletin* sets the date of extension at January 1st, 1875. Dispatches to some of the daily papers set it at July 1st, 1875, others July 1st, 1874, and others again to June 1st, 1875. The House committee on mines and mining, after the Senate had passed the Bill extending the time to January 1st, 1875, voted to report a bill extending it to May 10th, 1875. However, the bill has passed both houses extending the time, and if it is only to the 1st of January, it is a respite. Before that time arrives the full text of the bill will be published, so miners may know the exact date.

This action will relieve the minds of many who have neglected complying with the law in hopes that Congress would extend the time for another year. Others, however, have complied with the requirements of the law and have done the necessary work, so as to be on the sure side in case Congress refused to extend the time. The latter feel a little sore about it just now, thinking, justly, too, that a matter of so much importance should have received the immediate attention of Congress and not been delayed until within ten days of the date which it was the purpose of the amendment to change. However, Congress does pretty much as it chooses in these matters, not always being desirous to allow important affairs to pass through its hands too soon; but whether this view is always taken for the advantage of the persons interested, or the individual members of Congress, is a question with the skeptical.

It is stated that the entire delegation from the Pacific coast and Territories opposed the extension, on the ground that Congress should stand by the mineral law or repeal it; but members from east of the Mississippi voted against the Pacific coast delegation almost solid. To the casual observer this seems rather strange, inasmuch as the delegation from this coast knew that the miners of the coast would be under pretty heavy expense in complying with the law. It has been stated that the amendment was gotten up for the benefit of Eastern parties owning mines out here; but we all know that for one mine owned in the East, there are fifty owned here. Moreover, most Eastern people who buy mines proceed at once to work them, while the prospectors and miners here often get ten or a dozen claims, and hold on to them, in order to sell. This being the case, if the section of the mining law of May 10th, 1872, which provides for the annual expenditure on each claim, was intended to compel owners of mines to work them, or give them up to someone who would, it manifestly trod on our toes worse than it did on those of eastern people. Taking this view of the case it seems rather strange that the amendment which relieved these miners from operation of the law for a year, was supported by the eastern delegation and opposed by the western. Still, our representatives may have concluded that it would be better for the country if those idle claims were either worked or thrown open for re-location, and they accordingly advocated the law as it stood, thinking that all the claims

worth anything would certainly be worked.

It seems after all, that placer mines did not come under the provisions of this section of the law, and no annual expenditures were required upon that class of claims. If this fact had been made known a couple of months ago, it would have saved considerable expense and anxiety among the miners of placer ground. The full text of the decision setting this matter at rest is given in another column. The mining towns throughout the Coast have had slight temporary accessions to their population

Improved Slotting Machine.

We illustrate this week an improved slotting machine made by the New York Steam Engine Company, 98 Chambers street. The works of this company are at Passaic, N. J., within 11 miles of New York city. The slotter shown on this page has an extreme stroke of $8\frac{1}{4}$ inches, and will slot to the center of 36 inches. The crank shaft is $3\frac{1}{2}$ inches in diameter, driven

NEW YORK STEAM ENGINE COMPANY'S SLOTTING MACHINE.

within the past few weeks, by the presence of those whose interests had to be attended to by June 10th. These persons will probably now regret that they took the trouble they did, but the towns and mines are none the worse off for it.

The placer miners, who during the fall and winter had much idle time on their hands, are now busy as bees, all over California, and joyful in the hope that their labors will be richly rewarded. The bountiful supply of snow in the mountains gives assurance that the washing season will be unusually long, and the amount of water will be plentiful.

One of Crocker's five-stamp mills is being put up in the Ohio mine, West Point District, Calaveras county.

by a differential crank motion, giving a quick return to the bar, the bar having a continuous guide, and is perfectly balanced by lever and weight. The crank motion is driven by gearing seven and a quarter to one, the pinion shaft having a cone of three changes, driven by a 3-inch belt; largest end of cone, 14 inches. The table has feed in three directions, viz: longitudinal, transverse and circular, and has a traverse of 16 inches longitudinally, and $16\frac{1}{2}$ transversely. The circular table is 20 inches diameter. All of the feeds are driven from one feed shaft in a simple and effectual manner.

The bar has a vertical adjustment of 10 inches. The wrought iron work is all case hardened. It is provided with patent hollow self-oiling counter-shaft, that will run, after once being oiled, twelve months, and is in every respect complete.

This company also manufacture Chapman's slotting and planing tool, which consists of a steel yoke bar which can be attached to the main slotting bar of any slotting machine. At each end of this yoke bar is a screw passing through the poppits or tool holders, and by these screws the cutting faces of tools can be placed at any required distance. The piece to be planed is placed in indexed centers, and by this means square bars, hexagon bars and nuts, octagon bars or pieces, and in fact any piece with two parallel sides, can be planed or pared with these tools. In attaching to a planer, the yoke must be fastened to clapper or tool box.

Mining Accidents.

A fearful accident occurred in the Consolidated Amador mine at Sutter creek on the 30th ult. The last cage was being hoisted at six o'clock, with five men on, when the bolts holding the reel broke, detaching the drum from it and letting the cage and wire rope into the mine, a distance of 1,700 feet, killing all in it. The Sutter Creek *Independent* says: The cause of this distressing event was the giving way of the braces holding the reel within the grasp of the clutch, when, causing the wheel to slip away, it became at once like a wheel on a spindle, and was, in a few seconds, revolving with such speed that no power at hand could check it. The cage alone weighs over 1,000 pounds, and the five men nearly as much more, one of them being over 200 weight. To this must be added the constant paying out of the immense cable, weighing many tons and 1,900 feet in length.

The fall was inevitable, notwithstanding the patent safety brakes on the cage, which only operate when the rope slackens. In this case, instead of the rope breaking, which would have caused the cage to stick on the timbers, the wheel containing the rope got loose on the shaft, so that the weight of the cage and contents kept the rope tight. The names of the victims are John Moyle, who leaves a wife and three children; Luke Glanovich, who leaves a wife and six children; Samuel James, family in the States; A. A. Corilas, who leaves a wife, and Frank Fallon, single.

At Columbia, while Andrew Vanderwerf was working on his claim alone on the 1st inst., a bank caved upon him, and the sand and rocks covered him in such a manner that he could not move or give the alarm. After lying there for 24 hours, suffering terribly, he was discovered by his friends, and taken out alive. He was sensible, and spoke some, but was soon relieved by death. He was a single man and had been mining for many years.

Michael O'Connor was caved upon in a hydraulic claim below Coloma, on the 26th ult., and was instantly killed.

Richard Preston, an old resident of Downville, was killed by a cave in the Bald mountain gravel mine at Forest Hill on the night of May 26th.

The Iowa mine, which is under the management of Samuel Owens, the efficient Superintendent of the Utah, is located on the old Virginia ledge, south of the Sierra Nevada and northwest of the Ophir. The old shaft, sunk several years ago, has been cleaned out and repaired to the depth of 204 feet. This company is going to work as though they meant business, and the encouraging prospects of other mines around them, located in close proximity to the Iowa, give strong hope of the development of a valuable mine. — *News*.

The new machinery in the Lady Bryan has been started up, and the new shaft will now be pushed ahead with vigor.

CORRESPONDENCE.

Economy in the Use of Quicksilver.

EDITORS PRESS:—As you have kindly offered the columns of your valuable journal, by inviting experimentalists to record the result of their labors while searching for a more economical method for the use of quicksilver, I take this opportunity to contribute something to the general stock of information, hoping it may interest others pursuing this subject.

Numerous experiments have been made with a view of determining the best means of saving mercury in our metallurgical operations; after many ineffectual attempts, it was found necessary to institute a more thorough examination of the subject, which led to important results in the Mexican patio process; viz: by restoring floured quicksilver or *dishecho*, there was found the means of preventing that metal from flooring while in use. A much smaller quantity may be used to recover the precious metals than is now employed. A great number of experiments have been made, and the only interest that can be attached to many of them is to enable the experimentalist to avoid certain features not desirable, in his future efforts. In your issue of April 18th, Mr. Hookine suggests that lead and copper balls can be amalgamated, which will secure a useful purpose in the working of gold and silver ores. I fully concur in the statement made; the idea has been anticipated, however, by letters patent granted to me, Dec. 12th, 1871.

While pursuing this subject later, I may mention that metals of easy solution in mercury are not the best fitted for the purpose of amalgamation; lead, tin, etc. are of that class. The more insoluble metals may be objected to from the difficulty of amalgamating them. The writer has now working in his amalgamator a quantity of iron and copper S's. The iron is readily amalgamated by first tinning the iron, or better still, zincing it, then replacing it by substitution. These two metals, copper and iron, act with great energy, no doubt from the electro-chemical action induced by the two dissimilar metals. With regard to the best method of using those metallic pieces or balls, it may be mentioned that the practical difficulties are avoided by the use of an invention especially directed to meet the case.

As this apparatus possesses such distinctive features from any now in use, a description of it will be given if so desired.

JOHN TURNERIDGE.

37 Pacific street, Newark, N. J.

Society of Engineers of California.

The following inaugural address was read before the Society of Engineers of California, at the meeting of May 5th, by G. F. Allard, president of the society. It gives some suggestions as to the work possible to be accomplished by this new society, which has been inaugurated under very favorable auspices:

Our society being now fully organized and in complete working order, it may not be out of place for me, as its presiding officer, to offer a few remarks setting forth the aims and purposes we have in view, and the various subjects that will demand our attention. The primary object of the society is the advancement of engineering science and practice, more especially as the same may be applicable to the engineering wants of the Pacific coast; at the same time we hope, by the means of essays and discussions, to furnish our quota to the general fund of engineering knowledge. We shall aim to promote that unity and cordiality of feeling which should ever exist between the several members of our profession; to aid and instruct the younger members, and to create in the older and more experienced members a laudable ambition to excel in their special branches, to spur them on to further study and research, to incite them to read up and keep step with the engineering progress of the times. It is also the intention of the society to provide files of mechanical and scientific periodicals, and to accumulate, as its means will permit, a library embracing those valuable but costly books of reference and descriptions of great public works, so indispensable as a guide to the engineer who has to plan and execute works of any magnitude. I am pleased to state, in this connection, that the managers of the Mechanics' Institute have kindly offered us suitable rooms for our meetings, and have expressed a desire to assist us to the extent of their ability.

I had intended to present to you a summary of the subjects that might be profitably discussed and investigated, but found the field of inquiry so very extensive that I can not do more than throw out a few hints which may serve as an index to our future deliberations. The city of San Francisco, for instance, is today demanding the solution of three weighty problems: First, how and from what source to procure a cheap and plentiful supply of pure, fresh water; whether from the watersheds of San Mateo or Alameda counties, whether from Lake Tahoe or Clear Lake, or whether from the mountain lakes on the western slope of the Sierras. Second, to mature and carry into execution an efficient and comprehensive system of sewerage, and co-relatives thereto, a corresponding system of permanent street grades; and third, to establish a new water front that will bring ship and car together and can be at-

tended with the least possible shoving of her harbor. Scarcely of less importance, is a satisfactory answer to this question: what shall be our future street pavement? whether of wood, stone or iron, or a judicious combination of those materials; whether of asphaltum mixed with sand, gravel or broken stone, or powdered limestone; or perhaps of iron slag, a substance that has recently introduced with good results in European cities. The policy of pumping up the salt water of the bay for purposes of sprinkling the streets and flushing the sewers, has been advocated both as an economical and sanitary measure. We want more light in the matter of constructing our houses proof against earthquake shocks and general conflagrations. We shall soon require increased facilities of travel, not alone in the city itself, but also to and from its suburban towns, and we may yet require a grand bridge to connect us with the rapidly growing cities across the bay.

Turning to the State at large, we are led to inquire into the best methods for promoting our vast mining industries; to extend and perfect our mining machinery; to insure ventilation in deep mines, and prevent accidents; to facilitate the extraction of ores at great depths either by hoisting or through adit tunnels; to provide canals and water ditches for our undeveloped gravel mines; to establish a definite and uniform *modus* or miners' inch, for buying and selling water, etc.

Again, the subject of irrigation is looming up in importance; how to distribute the rain fall where it is most needed without depriving the more favored localities of their just quantities of moisture. On the other hand, we may examine the subject of reclamation, and suggest the most feasible and economical plan for reclaiming our salt marsh and tule lands; how to accomplish that object without incurring the risk of flooding the adjacent uplands by an undue contraction of the present waterway. Intimately connected with irrigation and reclamation, and in a measure resulting therefrom, is a system of navigable canals for transporting the surplus staples due to the increased fertility of the soil and the greater area brought under cultivation.

Referring to railroad matters, we find that the "war of the gauges," after a truce of some twenty years, has again been inaugurated. The question now is: shall the gauge of the future be a wide gauge, narrow gauge, or no gauge at all, as is the case in the single rail system? Each theory has its warm advocates, and the controversy is carried on generally with more feeling than judgment. As I look at it, the great desideratum in railroad practice is not so much the fixing upon any particular gauge, as it is the perfection of the present railroad rail; wanted, namely, a rail that shall be as strong and inflexible at the joint as in any other part. I am satisfied that nine-tenths of the wear and tear of track and train are due to the increasing sledge hammer blows caused by the passage of the wheels over the imperfect joints. Innumerable devices to that end have been invented and patented, but as yet the vexed problem remains unsolved.

The substitution of iron where wood is now used, as in bridges, bridge piers, buildings, for piles, railroad ties and cars, for mine supports, for telegraph poles (already adopted in Germany and Sweden); the substitution of steel where iron is now used, as in railroad rails, locomotives and other machinery; of wrought iron in the place of cast iron, as in tubular bridges, in water pipes, etc; the protection of iron exposed to the action of sea water; the preservation of wood from the ravages of the teredo and other sea-vermin; all these subjects are well worthy the patient investigation of the engineer. I refer to the introduction of steam as a motor on common roads, in the grain field and on inland canals; the transmission of packages, and may be passengers, through pneumatic tubes, or by means of wire ropes. The subject of boiler explosions, of railroad and steamboat accidents should likewise be taken up and adequate preventatives suggested. In short, there is no end of material to work upon. Let each of us, then, take in hand what he understands best, and in a well written essay present the result of his labors to our society. If found worthy it shall be published in our future annals for the benefit of the outside world.

In concluding these cursory remarks, I wish to congratulate you, gentlemen, upon the favorable beginning already made. May we continue to increase and multiply. At the same time I would advise caution and circumspection in the admission of new members. However desirable a large membership might be, let us look to quality rather than quantity; let us keep our standard high, so that to be a member of the Society of Engineers of California shall not signify, merely, that a certain party has paid his initiation fee and monthly dues, but that he stands acknowledged an expert in one branch, at least, of our honored profession. By adhering to a rigid policy in this respect, we may hope to draw around us, in course of time, the ablest talent on the Pacific coast, and compete, in point of numbers, respectability and influence, with the long established kindred associations in the eastern States and in Europe.

MINING SALE.—We see by the *Eureka Sentinel* that John R. Murphy and associates have bought the Industry, Chief of the Hill and other mines in the same series, for \$10,000.

THE Box mine, in Little Cottonwood, Utah, has been sold to a Chicago company for \$30,000.

The Sierra Nevada.

The *Enterprise* says that the improvements being made by this company are the most important now in progress anywhere on the Comstock lode. Their work, when completed, will be the most extensive and powerful ever erected in the State. The main building of the hoisting works will be 105x45 feet in size; the wing for the carpenter shop will be 45x30 feet, the boiler room the same and the blacksmith shop 25x30 feet. Eight or ten carpenters are already at work framing the timbers for the main building, and the foundations for the machinery and buildings will be so far completed that the majority of the masonry will be discharged to-day. A few men will be retained to assist in putting up the cut stone, upon which will be bedded the machinery. This work will be completed next week. The heavy influx of water still continues at the bottom of the main shaft—continues unabated. The shaft is 425 feet in depth, and at a depth of 420 feet—just where the water comes in—a pump station is being put in. This station is of a large size, and is being constructed with a vaulted roof. The tank for this station will be 14 feet long, 8 feet wide and 7 feet deep. The work of putting in this station, tank, etc., is about half completed. When the tank is finished and ready for use, the work of sinking the main shaft will be resumed. The timbering of the drain tunnel will be completed in about two weeks. It is being timbered in the most substantial manner, as it is quite probable that in course of time a track will be laid in it and ore will be run out through it—the flume for carrying away the water pumped from the mine being laid beneath the car track. The flume through which will be worked the company's hydraulic diggings is completed, and the wooden blocks that are to be laid in its bottom arrived from California yesterday. The hydraulic pipe for these diggings is not yet completed, owing to an accident to the machinery used in punching the sheets of iron of which the pipe is made, but all will be in readiness to start up week after next. The ho-e and all else is in readiness. At the old mine all is going on as usual. The yield is sufficient (55 tons per day) to keep the company's mill in constant operation, and the quality of ore remains about as usual. In regard to the new shaft, we may say that it is the intention of the company to put it down to the depth of 1,200 feet before starting their first drift. Even then the work of sinking will not cease, as the shaft will be put down to the depth of 2,000 feet before any halt is made.

Nevada District.

We have made mention of the above named district in the columns of the *News* on several occasions, and have pronounced it a most promising locality. Now, however, new discoveries have made the promises of its early history a certainty, and tangible proofs of its richness are being daily given in the quantity and value of rock produced. To Frank Almon, one of the original locators, we are indebted for the following facts regarding the locality: Nevada district is situated about twelve miles east from Mineral City, and the mines are found in the low range of mountains visible from the road leading down Steptoe valley. For many months several prospectors have been quietly at work developing their various locations, and are now being rewarded with splendid results. The Sumner mine is the principal property at present, and has been recently sold to the Watson Mining Company for a considerable amount. The croppings on this ledge are traceable for nearly 500 feet, and work has been done in various places its entire length, revealing rich and considerable bodies of free milling ore. A perfect foot wall has been discovered and is being followed steadily downward. Some specimens exhibited to us are equal in richness to those found in the famous Eberhardt of early days, being interlarded with horn and ruby silver which will make it assay away up into the thousands. D. T. Elmore, superintendent of the Watson Company's property, has put some forty men at work on the mine, and is confident of making a big run at his mill on the product of the same. It is gratifying to know that our neighbors at Robinson and vicinity are meeting with so great encouragement in their mining operations, and it is to be hoped that the many months of hope deferred have now given place to a season of prosperity, with the permanency of the mines fully assured. At Nevada, a town-site has been selected and laid off, possessing all the adjuncts for a town, with abundance of good and water. It has been called Tamarlane. The energetic proprietors have our best wishes for a numerous population, and, if present appearances are not deceitful, we anticipate an excitement to result from discoveries made there. A stage line has been started from Mineral City to the mines, rendering it an easy matter to visit the new camp.—*White Pine News*.

MOHAVE.—News from Mohave county, Arizona, is to the effect that mining matters are making good progress. The Keyetone has reached a depth of more than 100 ft. Considerable difficulty has been experienced in working the steam pump. It has also caused much delay, but it is now thought that the trouble has been overcome. The mine has improved very much, indeed. The ore is rich, say \$250 per ton, and the ledge three feet wide. Much of the ore will assay more.

Idaho Mines.

We take the following mining notes from the *Owyhee Avalanche*, published at Silver city, Idaho: The stope between the fifth and sixth levels of the Golden Chariot, and between the sixth and seventh levels of the Minnesota continue to look splendid and are yielding very rich ore. The other portions of the mine are also looking first-rate. The ballion yield of the Golden Chariot for the month of April was \$55,135.55. We learn from a reliable source that the Golden Chariot company has purchased the New York mill for \$40,000—cheap at that price.

The prospects for the Mahogany are excellent, and it is confidently expected that the eighth level will turn out more million than did the seventh. Judging from present indications the ninth level will be better than either the seventh or eighth.

Superintendent Carter has been compelled to suspend sinking the War Eagle shaft for the present on account of the large amount of water coming into the mine. The sixth level north continues looking splendidly.

The Red Jacket gives indications of soon striking something good in the main shaft.

The Empire continues looking as well as ever, and Superintendent Hoyt will commence milling ore as soon as the roads will permit of hauling, which will probably be week after next.

The South Chariot still continues to open up splendidly. A recent assay of average ore taken from the bottom of the seventh level winze, gives gold \$197.40 and silver \$89.70; total, \$287.10 per ton.

Just as we go to press the news reaches us that they have struck a two foot ledge in the eighth level drift of the South Chariot; richer ore than any hitherto found in the mine.

Judge Martin informs us that he is compelled to suspend work in the Glenbrook, on account of the large quantity of surface water coming into the mine from the melting snow in that vicinity. He has a nice pile of ore on the dump which will be milled as soon as he can get it hauled. The Glenbrook will astonish the natives this summer.

Superintendent Boyle expects to make the Silver Cord a dividend paying mine before the summer is over.

The surface water caused by the rapid melting of the snow in the vicinity of the Ida Elmore, seriously interferes with the working of that mine at present.

The placer mines are now in full blast. The hydraulic claim below the Elmore mill, on Florida mountain, is running night and day, with a good head of water.

Several parties have commenced doing the necessary work to hold their claims under the new mining law, which takes effect on the 10th day of June.

The prospects of this mining camp are decidedly better than they ever were before, and at least double the amount of bullion will be produced here this summer than during any previous season.

Iowa Hill Water-Ditch.

A correspondent of the *Bulletin*, writing from Iowa hill, Placer county, gives the following detailed description of the Iowa hill water-ditch, which it is anticipated will greatly aid in the hydraulic mining of the district:

The ditch was commenced about twenty months ago, and the people of that section have been looking forward to its completion with no ordinary amount of interest.

The main canal, 5 feet on the bottom, 4½ feet deep, with a capacity of carrying 7,000 inches of water, was completed some 25 miles last season, allowing about three weeks' work more to finish certain minor points. The first large reservoir is about eight miles from town. This, now containing about 30 feet of water, and covering some 64 acres of ground, will be raised this season at the wall to 50 feet in height, which will then give 48 of water and cover 100 acres of ground. The water in this main reservoir is now available for mining. From this central reservoir the main canal proceeds past the Forks' House to Tadpole, New York, Sailor, Long, and by cañone tapping all in turn to the North Fork of the American river, making a total distance of 40 miles. The total cost with reservoirs will be \$500,000, of which \$95,000 have already been expended.

To insure a constant supply of water, to the capacity of the ditch at least, throughout the year, the company have several excellent reservoir sites in different places, namely: One at Sailor's Cañon, 25 acres; one at Big Cañon, 25 acres; and several at the head of the ditch, which probably will cover 500 acres more. In the event of those not being sufficient, a tunnel will be run through a gravel ridge 2,500 feet long, to connect with the waters of the Middle Fork of the American river. This district for years past has only had water for about three months in the year, and yet yielded from \$160,000 to \$300,000 per season, miners working through short days, and with a very limited supply of water. It is, therefore, safe to say, when this ditch is thoroughly completed, the receipts of gold from the Iowa hill district will approximate, if not exceed, \$1,000,000 per annum.

PROSPECTING on the hills immediately around Pioche and its neighborhood is being resumed to a considerable extent.

RENO has subscribed \$2,650 toward building a road from that place to Loyalton, Sierra valley.

SCIENTIFIC PROGRESS.

Electroplating.

(CONCLUDED.)

The galvanoplastic art has extended itself in three directions: 1. For covering other metals, as in electroplating with gold, silver, copper, steel and nickel. 2. In producing objects formerly cast in metal. This has been brought to great perfection in several German cities, especially Mayence, where the smallest natural objects are copied and the largest works of art produced. Among the latter are three colossal figures on a monument in Frankfurt. 3. The reproduction of engraved and stereotyped plates, and the like. In the latter, farther progress is still possible.

Early in 1840, Pélégot reduced protochloride of iron by passing hydrogen gas over it, and in this way obtained metallic iron in octohedral crystals and in malleable plates. In 1846, Professor Bottger made the first attempt to decompose the chloride of iron by the electric current, and with success, but soon found that a mixture of the double sulphate of iron and ammonium and the double chloride of iron and ammonium was better for electroplating. As anodes he employed a piece of sheet iron; the cathode at once acquired a polished appearance from the metallic iron deposited on it. The iron is very hard, like steel, but unfortunately very brittle, so that it frequently breaks in taking it from the mold. No technical use could at first be found for it. In 1859 Jacquin found an application of it in covering copper plates with steel. This consisted in precipitating on the copper an extremely thin film of iron, which did not destroy the sharpness of the impression, but by its hardness offered such a protection to the copper that the latter was almost as durable as a steel plate.

Recently, a chemist in St. Petersburg, also named Klein, has brought electroplating with iron to a remarkable degree of perfection. In 1868 he deposited the iron in large plates both thick and thin, as copies from engraved copper plates, and thus combined a soft, easily wrought plate for the engraver, and an iron plate as hard as steel for the printer. The iron thus deposited was very brittle. By heating the iron, he succeeded in expelling the hydrogen, when it became more dense, and had a specific gravity of 7.811, which is higher than wrought iron. It was perfectly malleable, highly elastic, and could be welded like sheet steel, in short, was an excellent malleable iron. Klein has prepared plates of this iron weighing 16 lbs.

Electroplating in iron will find an important and extensive use in manufacture of stereotype plates, especially for printing government paper and postage stamps, where colored inks are employed, for the iron would not be attacked by the colors containing mercury, which acts on copper and other metals.

Hardinger believed that he could prove that the surface of the earth was the anode and the interior of the earth the cathode of a galvanic battery. According to this, native metals should only be sought deep down in the earth, which is not always the case. It is much more probable that native metals have been reduced by the decomposition of organic matter. This applies especially to copper, and also to the very rare telluric iron. The graphite found in the latter is to be considered as the residuum of decomposed organic compounds. In the Rotanger sea in Sweden, native iron is found replacing particles of wood, as if petrified, and the microscope is able to detect the cells and determine that it was a species of pine wood. The interior of the cells is also filled with a deposit of iron. This is not to be attributed to the action of a galvanic current, but to the reducing power of the hydrogen liberated from the decomposition of organic matter.

A NEW THEORY OF WATERSPOUTS.—It has been hitherto assumed that the column of air which revolves to produce a water spout is an ascending column. M. Faye, the astronomer, has recently maintained before the French Academy the theory that the air in these columns is a descending one. Precisely as in a river, vertical layers of water, moving with different velocities, form whirlpools in shape like funnels, drawing the water away from the center, so, when currents of air above the clouds move in different directions, or in the same direction with different velocities, they produce upon their borders a gyratory motion of the interposed air. This air descends like the water in the whirlpool, and if the gyratory movement be powerful enough, the tube of rotating air may reach the earth. At the same time the centrifugal force determines the matter to the exterior, and causes a partial vacuum in the interior, thus explaining the lifting of objects over which the whirlwind passes, and in the case of water producing waterspouts. Of course the barometer in the center experiences a sudden fall. The solar spots Faye explains in this way, supposing them to be whirlwinds seen vertically. The solar gas drawn into them being cooler, appears as the dark umbra.

M. G. TISSANDIER, the editor of *La Nature*, is completing a series of observations, for calculating the amount of atmospheric dust falling each day. The mean found is said to be several pounds in twelve hours for a surface not larger than half a square mile.

The Earth's Strata.

The greatest depth yet attained, says Dr. Chandler, into the bowels of the earth, below the sea level, is at Minden, Prussia, where, at the salt works, the boring extends 1,970 feet below high water. Other mines are of greater depth from the surface, as the old one at Kurtenburg, in Bohemia, which is 3,545 feet in depth; yet its bottom is above that at Minden. But the geological revolutions afford us a means of investigating vastly deeper into the crust of the earth. During the interminable ages that have passed since the crust has been cooling, from a once molten or incandescent condition, mighty and violent revolutions have from time to time taken place. As the earth's temperature has constantly been subsiding by radiation, a corresponding diminution in size has been the natural sequence. In this manner protuberances and corresponding depressions have been formed, which we call mountains and valleys. Other agencies co-operating with the lowering of the temperature of the earth, have caused the lower strata to be so tilted and bent as to be at, or near, the surface, in inclined or carved positions, and geologists have thus been enabled to study the material constitution of the globe to the depth of seventeen miles. Of the many evidences of this abrupt displacement afforded in various parts of the earth, perhaps none are more manifest and conclusive than those at Herkimer county, N. Y., where geologists have most positively determined the formation and elements of our globe to the depth of sixteen miles. The chemist has proved that the materials revealed consist of sixty-six elementary parts, and that sixteen of these, united in different combinations and proportions, form nearly all the known matter of the globe.

ALL bodies get larger as they get warmer. To this rule there is no exception amongst gases, and only three or four amongst liquids and solids, and these exceptions only occur at special temperatures. A solid without any structure—that is, having neither a crystalline form nor any kind of lamination or fibrillation, or "grain," expands the same fraction of its measurement in all directions when heated. A sphere will remain a sphere, a cube a cube; the hot body will be as similar in shape to the cold one as a near body is to a far one. Thus a wire a hundred inches long and a hundredth of an inch thick, will, when heated to a certain temperature, increase a hundredth of its thickness and a hundredth in length, thus increasing one ten-thousandth of an inch in thickness, and one inch in length. Instead of taking wires of enormous length in order to get appreciable elongation, we can multiply the apparent elongation by the mechanical means of levers, or optically. The examination of the expansion of liquids is more simple, because they have merely to be enclosed in flasks provided with narrow tubes, the bores of which may be made exceedingly small in comparison with the capacity of the flasks. When such vessels are heated, the glass at first expands, and forms a flask of greater capacity, so that the liquid falls in the tube. But anon the liquid expands, and as, invariably, the expansion of a liquid is greater than that of glass for the same increase of temperature, the liquid rises in the tube.

PLATE-GLASS STAINING.—Stained glass is daily becoming more popular in all styles, and since the introduction of polished plate glass—whose sole ornamentation hitherto has been embossing—various attempts have been made to solve the problem how a large plate could be stained with vitrified colors, so as at the same time to preserve uninjured the polish on the reverse side. The difficulty was the circumstance that the flames could never be made to play equally on so broad a surface. One part of the work invariably became heated before another, and the result was breakage and failure. The plate to be stained is placed in an iron box of a novel description. One side of the plate is imbedded in a powdered preparation; the other, with the vitrified colors upon it, is, of course, left exposed; and the peculiarity of the furnace is, that while the heat is brought to bear equally upon the upper surface, so that it softens and readily absorbs the colors, the under side is kept so cool that the polish upon it is entirely uninjured.

A CORRESPONDENT of the Scientific American says: I have in my possession a live fish which has the body and tail of a dog fish, and the head of a cat fish. Its habits are those of a cat fish, sleeping in the day time and waking at night. I presume that it gets this habit from the head. It is clearly a hybrid of the two kinds. Here is something for the development theory.

BEQUEREL has succeeded in producing artificially many native crystalline minerals, such as malachite, arragonite, by the slow action of solutions of some of their elements on solids containing the other elements; but the time required is very long, namely, from two to twenty years. He has thus illustrated the manner in which these bodies have been formed in nature.

JANNETAZ calls attention to the fact that a fragment of bisulphate of potassa thrown upon coarsely powdered galena gives rise to an immediate development of anhydric acid gas. With the sulphide of antimony, iron, mercury and silver, no sensible disengagement of gas is obtained.

MECHANICAL PROGRESS.

Japanese Dentistry.

An American dentist, living in Yokohama, gives the following account of the Japanese habits in regard to their teeth. He says that as the young women have very fine teeth, it is remarkable that they should keep up the practice of blacking them after marriage. The Japanese, as a race, possess good teeth, but they lose them very early in life.

Their tooth brushes consist of tough wood, pounded at one end to loosen the fibers. They resemble a paint brush, and owing to their shape, it is impossible to get one behind the teeth. As might be expected, there is an accumulation of tartar, which frequently draws the teeth of old people. The process of manufacturing false teeth is very crude. The plates are made of wood, and the teeth consist of tacks driven up from under the side. A piece of wax is heated and pressed into the roof of the mouth. It is then taken out and hardened by putting it into cold water. Another piece of heated wax is applied to the impression, and, after being pressed into shape, is hardened. A piece of wood is then roughly cut into the desired form, and the model, having been smeared with red paint, is applied to it. Where they touch each other a mark is left by the paint. This is cut away till they touch evenly all over. Shark's teeth, bits of ivory, or atoms, for teeth, are set into the wood and retained in position by being strung on a thread, which is secured on each end by a peg driven into the hole where the thread makes its exit from the base. Iron or copper tacks are driven into the ridge to serve for masticating purposes, the unequal wear of the wood and metal keeping up the desired roughness. Their full sets answer admirably for the mastication of food, but, as they do not improve the looks, they are worn but little for ornament. The ordinary service of a set of teeth is about five years, but they frequently last much longer. All full upper sets are retained by atmospheric pressure. This principle is coeval with the art. In Japan dentistry exists only as a mechanical trade, and the status of those who practice it is not very high. It is, in fact, graded with carpentry—their word *hadyikefsan* meaning tooth-carpenter.

IMPROVED BURGLAR ALARM.—The object of this invention is to provide simple and convenient means for detecting burglars when entering buildings; and consists of an alarm movement and bell in combination with a wire or cord and gas burners, so arranged that, in the act of opening the door or window with which the alarm is connected, gas is turned on, a flame produced and the alarm given. A wire or cord is attached to an arm in the wall and to a second arm, which is attached to and projects from the escapement shaft of the alarm movement. The alarm movement is wound up by means of a key on the main shaft, and is held and prevented from giving the alarm by the wire. This wire is attached to the vibrating escapement shaft by a crank, so that the movement is held stationary by it. When this wire is broken or parted the alarm is given. A gas pipe is connected with the service pipe, and the burner on the end thereof is supplied with a small jet of gas, which is ignited when the alarm is set for use. When the door is opened a bar is drawn back, a gas cock is turned which admits of a flow of gas through a pipe to a second burner. The two burners are so formed and placed so near each other that the gas which escapes from the second burner is ignited by the flame from the first burner. The former gives a full flame, which envelops the wire and in a few seconds burns it off, and allows the alarm movement to vibrate the hammer and give the alarm.

ELECTRO SYMPATHETIC CLOCKS.—The master clock, which is one merely of an ordinary kind, requiring to be wound up periodically, is placed on the platform of the large hall. The oscillations of its pendulum are used to complete contact between the poles of a galvanic battery, placed on the top of the clock case. There are two cells of the ordinary "Daniell's" sulphate of copper battery, one pole of each being placed in metallic connection with the gas pipe, and the other pole terminating in a slender spring, against which the pendulum rod impinges; and while contact is thus obtained alternately with one or other spring, a current of positive or negative electricity is sent through the pendulum rod, along the insulated wire connected with it to the other end of the hall, where the sympathetic clock is placed.

THE NEW PRUSSIAN NEEDLE-GUN.—The lock of the gun is an improved needle-lock, arranged for self-cocking, and combines the simplicity and solidity of the needle system, with quick and convenient loading, with rapidity of firing equal to the best rifles. The lock consists of six parts, and the loading requires only three movements—the opening of the chamber, by which operation the lock is cocked at the same time; throwing in of the cartridge into its bed, it not being necessary to put it in exactly; and closing of the chamber. The gun is now ready for firing. The empty cartridge is ejected at the next opening by means of an extractor, fixed at the movable round of the chamber. The maximum number of shots per minute is 24.

Armor Plates.

Armor plates were first used in the construction of ships of war in the case of an iron steam battery for the harbor defence, commenced in Hoboken, U. S. in 1844. At the suggestion of the Emperor Napoleon some floating batteries, clad with four-inch armor, were built during the Crimean war, and employed in some of the operations in the Black sea, but these as well as some built by the Admiralty in imitation of them, were of very little use, on account of their clumsy form, and it was not till the advent of the French *La Gloire* and *Warrior* that it began to be seen that the war ships of the future would be iron-clads. In 1861, when the *Warrior* was built, it was believed that, while the thickness of her armor (4½ in.) represented the maximum of weight which a seaworthy steamship could carry on her sides, it, at the same time, provided a defence practically invulnerable. Both these views were soon shown to be defective, and it is now seen to be practicable to build, as well as desirable to have, seagoing iron-clad ships with armor averaging seven inches in thickness, and in some large ocean cruisers, without masts, 10 to 12 inches of armor have been used on their sides, and 12 to 14 on their turrets. Nor does this great increase in the thickness of armor constitute the sole advantage which recently constructed iron-clads have over the *Warrior*. Besides the important consideration that the armor is so distributed over the surface of some of our latest iron-clads that a belt at the water line throughout the ship, and other really important parts are protected, which is not the case with the *Warrior*, where merely the middle portion of the ship is iron-clad, it must be added that armor plates are now better made and are fastened to the ship's side much more securely than formerly.

Judging from recent improvements, it seems quite possible that armor plates in the future will be much heavier than are now used, and will be restricted to the defence of the more vital parts of the vessel, as in the *Infexible*, where two feet of armor plating has been laid on

THE WHITEHEAD FISH TORPEDO.—The report of Commodore Kirkland and Master Berwind, of the United States navy, sets forth the performances of the torpedo during the trials conducted recently by the Italian government. The main point to be determined was whether the fish would, after being lowered down several feet below the surface of the water in a directing tube, and then started, proceed in a direct line for several hundred feet. The result of the experiments proved that the torpedo would run 600 feet in 35 seconds, that is, 10½ knots per hour, under 50 atmospheres pressure, and maintain its direction perfectly at four and five feet immersion; that it would run 4,500 feet at seven knots per hour, under 57 atmospheres, with a slight deviation; that the device could be easily launched and accurately directed from an ordinary boat, and that changes of depth can be effected at the will of the operator, without impairing the qualities of the torpedo. In conclusion, the reporting officers endorse the apparatus in the highest terms.

BRONZE CASTING UNDER ARTIFICIAL PRESSURE. A cast iron platform is laid on foundation walls; and upon the former rests, first, the ground plate of the mould, and secondly the mould itself, which is of great strength. This mould is surrounded by a heavy cast iron jacket, which is bolted to the platform; springs are arranged to protect the bolts and other parts of the apparatus against the effects of the dilatation of the mold after the running. The cover is furnished with a cylinder formed of clay or other bad conductor of heat, and on this is placed a metallic piston with a pocket or receptacle. The piston and pocket form one solid piece, which is supported in its position at the required level by iron bands. The opening for the metal as well as the pocket is lined with fire clay. The upper part of the mold and the interior surface of the cover are also lined with fire clay, in order to retard as much as possible the cooling of the upper part of the casting. The air and gases escape from the mould by means of several conical vents.

A NOVEL dining table is now in use in one of the palaces of the Emperor of Russia. The table is circular, and is placed on a weighted platform. At the touch of a signal, like a rub of Aladdin's lamp, down goes the table through the floor, and a new table, loaded with fresh dishes and supplies, rises in its place. But this is not all; each plate stands on a weighted disk, the table cloth being cut with circular openings, one for each plate. If a guest desires a change of plate, he touches a signal at his side, when, presto, his plate disappears and another rises. These mechanical dining tables render the presence of servants quite superfluous. In this country, at the Oneida Community, they employ dining tables having the central part made to revolve. Here the goblets, spoons, tea and coffee, casters, pitchers and other necessary articles of table furniture are replaced; revolving the center piece, the waiter brings before him whatever article may be desired without the intervention of a special waiter.—*Builder*.

THE FLIGHT OF BIRDS.—M. Penaud now demonstrates, first, that a bird sailing in the air falls as slowly as possibly when he employs for his horizontal movement one-fourth of the work of the fall; second, a bird sailing with a uniform movement clears a given space with the least possible fall when the work of suspension is sensibly equal to the work of translation.

this rich ore was rapidly widening, and the thing was to be kept "dark."

WEST POINT DISTRICT.—Zacetero building mill. Large quantities of high grade ore are being taken from different portions of the mine. Mina Rica shaft is down 80 ft. Hoisting works will be put up immediately. Beyond don't this mine will give a splendid account of itself when once fairly opened. A 20-stamp mill is to be erected on the Woodhouse, the mother lode of Oalaveras county; preliminary work is being done. The Granite Crown, another enormous lode, containing, on the average, low grade ore, will also be put in working condition.

MORE GOLD—BIG CLEAN-UP.—Veith & Co., proprietors of the great hydraulic in Tunnel ridge, "cleaned up" \$2,400 Tuesday last, the result of 16 days' run. The yield of the mine increases with each clean-up, the gravel proving richer the farther back in the hill it is obtained. We are glad to know that all the hydraulics in this vicinity are paying handsome dividends, and that the field of operations is constantly being enlarged.

FURTHER RETURNS FROM SAN BRUNO.—About 100 tons of rock taken from the San Bruno mine at Mosquito, put through Garland's mill at that place, yielded 161 ounces of gold—nearly \$3,000.

ANOTHER NEW QUARTZ MILL.—Several quartz mills are now in progress of erection in this portion of the county, and we hear that preparations are being made for putting up still another. A ten-stamp battery is to be built on the Austrian mine near Whisky Slide, workmen being now employed getting out the timber. The motive power is to be water, and it is expected to have the battery in readiness for crushing in about a month.

COLUSA COUNTY.

QUICKSILVER EXCITEMENT.—*Sun*, May 30. The hills and mountains west of Bear valley are thronged with men who were formerly farmers, but who now are searching the hills for quicksilver. There are already six or seven claims located, but still they are searching for indications of the precious ore. It reminds one very much of the early times of California, when every one who could muster together money enough to purchase a pick, shovel and frying-pan, was marching for the land of gold, and it is certain to result as unsatisfactorily to some as the gold mines did to a great many. While some will find very profitable mines, others will spend their time and money without realizing any profit. We think that Colusa county can look ahead to the time when she will be noted for her mineral wealth as well as for her agricultural. She has already several paying mines. Among these are the Buckeye, Abbott and Elgin mines; and when these new mines become developed, she will stand among those counties which are mentioned as being famous for their mineral wealth.

QUICKSILVER.—Stewart Harris went out to the quicksilver region during the first of the week, jumped into a hole on the Lovelace claim, took out four pounds of dirt, retorted it in an old quicksilver tank, and brought in with him twelve ounces of pure quicksilver! He did all this with his own hands, in order to be certain about it.

EL DORADO COUNTY.

WHITE OAK ITEMS.—*Mountain Democrat*, May 23: A correspondent writes as follows from Wing's Precinct under date of May 26th: This has been an unusually busy season with our surface miners. But, as usual at this season of the year, the cry is "more water," and the inquiry is, "when will we have this great want of our miners supplied?" Our quartz interest is in course of active development and gives fine promise of good remuneration. Hon. George E. Williams has, I am informed, bonded the celebrated Gray mine, situated on Gray's Flat, and will immediately commence work. This is considered one of the best mines in the county. There is a shaft on the mine one hundred feet deep, and a twenty-five horsepower engine and all necessary hoisting machinery for the successful working of the same. Granger and brothers have been making rich discoveries on what is known as the old Shirley vein, situated about one mile south of the Gray mine, and it is reported that they have already taken out several thousand dollars. All the experienced miners who visit this section concede that there are few mining localities which will exceed this in richness when fully developed.

MINING ITEMS.—Bennett & Swift, of Georgetown, are working in a pay seam in their mine. There is a great deal of gold in their claim, and they are taking it out as fast as they can.

H. J. McKusick is Superintendent of the Cal. Water Co.'s mine at Georgetown.

The rock in the Taylor mine improves as the shaft gets deeper. The crushing machinery will soon be at work.

Work is still progressing at the Woodaide mine. The proprietors think the hoisting machinery will be at work by the first of June.

RICH STRIKE.—A letter from Garden Valley, dated May 29th, notifies us that in the Taylor mine, at the 400 feet level, a splendid development has just been made. They have made a cross-cut 9 feet in thickness, and not yet through the ledge, the rock showing gold freely as far as they have cut into the ledge. Our correspondent is jubilant, and says that "Any one thinking the quartz mines of El Dorado are played out, had better visit the St. Lawrence and Taylor to be convinced of their error. Depth is all that is wanted."

PETER CROSS, who has just sold his claim in Big Cañon for \$15,000, will soon be at work developing another, which he believes will

prove as good or better than the one he has disposed of. It is a pity we have not plenty of such preserving prospectors as gross.

LAKE COUNTY.

PINE FLAT MINES.—*Bee*, May 28: J. W. Mackall, who has just returned from a visit to Pine Flat, gives us the following information regarding the quicksilver mines of that region: The RattleSnake is owned by Parrott, Lightner & Co., of San Francisco. They have about 70 men employed, and will erect a furnace as soon as the new road to Hardsburg is completed. The Sonoma mine has struck a rich deposit of metal. They have a Knox & Osborn furnace of 13 tons capacity, and are producing about 60 flasks of quicksilver per month. Owned by Col. Dodge, of San Francisco. The Flagstaff contains very rich cinnabar, and it is stated that the proprietors will immediately erect furnaces. The Socrates is one of the oldest mines in the district, is well developed and shows rich mineral. It is owned by W. S. Bell, the Recorder of the District, and others. The Georgia has a great quantity of rich ore in sight. Is owned by Messrs. Thompson, Reynolds and others. They are working ten men. The Cedar, New York and Pacific mines are owned by Lakeport men, Messrs. Sleeper, Forbes, Parrish and Mackall. They are working 10 men, and the mine promise to be very valuable. The Fleetwood is prospecting well. It is owned by Mr. Williams, the proprietor of the town site of Pine Flat. The American mine was sold a few days ago to San Francisco capitalists for \$125,000. The Bacon mine is prospecting well; also the Oak Grove and the Sotoyome mines.

MENDOCINO COUNTY.

MINES AND MINING INTERESTS.—*Dispatch*, May 30: A rich deposit of cinnabar has been discovered near the Soda Spring between Ukiah and Anderson Valley, and a company has been organized for the purpose of opening the mine. The lucky parties are F. M. Hunt and brother, E. Morris and W. P. Owen. The surface rock has been assayed, and from two ounces of rock $\frac{1}{2}$ of an ounce of pure metal was extracted. Work was commenced on Monday last, and is being vigorously prosecuted. In Potter, also, important mineral discoveries have been made, quicksilver, and red oxide of iron, valuable for paint. The hills are full of eager and sanguine prospectors.

NAPA COUNTY.

FROM THE YELLOW JACKET.—*Register*, May 30: Mr. Wm. A. Stuart, of San Francisco, went down on Thursday morning from a visit to the Yellow Jacket and neighboring mines, and reports the prospects as most flattering. A new mine, called the Ida Clayton, is opening out splendidly, and in Mr. S's opinion, promise to be the best mine up there. A survey recently made locates the Yellow Jacket and others in Napa county, instead of Sonoma, as they have heretofore been supposed to be.

OUR SILVER MINES.—*Calistoga Free Press*, May 30: A little over a year ago the existence of a well-defined lode of gold and silver-bearing quartz was discovered about six miles from this place. The indications of the existence of ore in paying quantities were so encouraging that the proprietors of the mine have employed a large force of men for the past year, who have worked three shifts night and day up to the present time. The Calistoga Mining company, who now own the mine, will shortly commence the construction of a first-class mill for the reduction of the ore. On Thursday morning last an additional force of 20 men was sent up to this mine, together with three wagon loads of lumber, 46,500 feet.

NEVADA COUNTY.

GOLD HILL MINE.—*Union*, May 30: Supt. Crase has let a contract in this famous mine to drive a cross-cut tunnel to tap the ledge at a point about 250 ft. in the hill. The object of the new tunnel is to re-work the ground above the water level, taking out the pillars and waste dirt now in the old works. The mine was worked in earlier days, but with modern appliances it can be re-worked with profit. The men will soon be taking out the pay dirt, and may strike a continuation of the ledge and tap new strings, which, if we judge from the past, will prove very rich. There are a large number of just such ledges in Graas Valley township that need only energy and capital to develop and place on a paying basis. "If they were worked the town would become much livelier and the mines themselves be of value to the stockholders. Let them be worked by all means."

Tidings, May 30: Richer and more of it is the cheering news from New York Hill. The ledge in the lower tunnel, which has been split along back, is now solid and about two ft. thick. A bucket full we saw from yesterday shows splendidly in free gold and sulphurets, and the foreman tells us there is a good five-inch strata of pure sulphurets lying under the ledge.

PLACER COUNTY.

THE BELLEVUE.—*Argus*, May 30: We visited the Bellevue during the past week and found the continued body of good paying rock mentioned in our last still plentiful and every indication of its continuing so. About sixty-five tons of test ore was taken from all the different parts of the Bellevue mine, which averaged \$36.50 per ton for the whole mine, in coin, aside from the sulphurets saved for shipments, which yielded from \$800 to \$1,000 per ton.

HIDDEN TREASURE.—We again visited the Orleans mine, owned by Mr. Gordon, during the past week, and find the same flattering indications as presented in our last visit.

THE ORLEANS.—During the past week several mining sharps from different points through-

out the State and Nevada have visited the Orleans mine. They all appear pretty well pleased with the appearance of the surroundings both above and below the mine—in the drift and on the dump.

SIERRA COUNTY.

STRUCK IT.—*Mountain Messenger*, May 30: We are informed that the Independence Quartz Mine, under the careful and intelligent management of Capt. Davis, has struck good pay ore in one of the levels, and put on an increased force of miners.

Willhourn & Burton have also gone to Woodchuck ravine to commence work on their claim. Coover & Williams have also gone to the same locality to commence opening their diggings. The snow is very deep in that section.

INDIAN HILL.—The mine at this point are yielding an abundant supply of gold this season.

SONOMA COUNTY.

THE CADRE MINES.—*Democrat*, May 30: Among the mines in this county, recently sold to capitalists, we may mention the Carrie mine, two miles south of Cloverdale, now known as the Live Oak. It was located in February, 1873, by J. J. Morrison, Jos. Dougherty, E. Ray and J. A. Carrie. The locators prospected the mine, proved its value, and it was sold to I. P. Allen and others, of San Francisco, for the sum of \$12,000. An extension on the ledge, known as Live Oak No. 2, was sold to the Hercules Mining Company of San Francisco. The mine are now being worked by the owners. We visited the Live Oak and found considerable ore upon the dump. The formation of the mountain in which the mine is situated is very regular and the strata less disturbed than is usual in this section. The matrix is serpentine rock, through which the cinnabar is diffused. A tunnel has been run into the hill, and they are now sinking a shaft on the ledge, taking out good ore.

THE CLOVERDALE MINE.—The claim embraces a tract of 68 37-100 acres. From the Big Sulphur to the crest of the hill the distance is about half a mile. Parallel claims have been located to the water's edge, and the whole face of the hill, embracing about 160 acres, is probably controlled by this company. We hardly know how to describe this remarkable mine. From an out-crop on the side of the hill considerable good grade ore has been taken. The singular features of the mine are that cinnabar is found not only in the out-crop of the ledge but in many places on the claim where there is no out-crop. Just below the surface, covered with the roots of the wild oat, we found rich specimens of cinnabar. It is found in all kinds of rock, in quartz, in sandstone, in magnesia; the richest and most beautiful specimens were in a sedimentary formation. The whole hill, so far as the surface indicates, has been permeated with mercury. The Cloverdale is an anomaly, even in this region of remarkable formation. A road is being constructed to the site selected for a furnace; active work will immediately commence. The owners, mostly residents of Sacramento city, have abundant capital, and Mr. Hall is an able and experienced superintendent. He is now working the California mine in Lake county. Near the Cloverdale is the Mt. Vernon, owned by Bell, Walther & Co., of Sacramento.

THE LIVERMORE MINE.—About six miles below, on the south side of Sulphur creek, the Livermore mine is located. Twenty men are at work. They have at least 500 tons of ore on the dump. The cinnabar is found diffused through a serpentine rock; a great mass of this rock has been denuded of surface earth and is being blasted and broken.

Nevada.

WASHOE DISTRICT.

BECKER.—*Gold Hill News*, May 28: Sinking the main incline has been suspended, pending the opening of the 1,500-ft. station. The ore stopes on the 1,400-ft. level are now opened out three floors, or 21 ft. in height, the ore being of excellent quality an improving one southward. The winze from the 1,400 to the 1,500-ft. level is completed. This gives a good circulation of air to that depth, and as soon as the north and south drifts are connected on the 1,400-ft. level, will enable the prosecution of the main drift southward on the 1,500-ft. level to meet the north drift on the same level from the incline. A new airshaft for the better ventilation of the mine has been started 200 ft. from the north line. This, although intended for air purposes, will be made a good working shaft and will strike the ledge immediately over the ore stope on the 900-ft. level. The ore stopes on the 1,000, 1,200, 1,300 and 1,400-ft. levels are turning out more ore at present than the mills can crush.

SIERRA NEVADA.—Daily yield 60 tons of ore, keeping the mill steadily running. The flow of water at the bottom of the new shaft seems, if anything, to be increasing rather than diminishing; the boiling tanks are kept steadily running, hoisting the water to the surface. The station for the water tanks and pump 420 ft. from the surface is complete. A large force of workmen are employed upon the new machinery and hoisting works building, which will be ready for erection by the first of next week.

CROWN POINT.—Daily yield 550 tons of ore. The ore stopes throughout the entire mine are looking well and yielding splendidly, especially those opened out on the 1,400-ft. level, which are yielding ore of a high grade, with promise of a much greater extent than on the level above. The north winze from the 1,400-ft. level was started up again on Sunday last, and the bottom still continues in rich ore. The

south drift from the north winze is being pushed steadily ahead, the face in ore that assays from \$300 to \$500 per ton. The milla are all running, and the mine promising and prosperous throughout.

UTAH.—Sinking the main shaft is progressing $2\frac{1}{2}$ feet per day. It is now down 60 feet below the 400-ft. station. The east cross-cut, 200 feet south of the main west drift, has struck and is now passing through a fine, healthy, solid body of quartz and ore, which gives assays of \$12 to the ton. This body of ore is entirely free from the base metals found heretofore on the level above, and is just such a formation as often precedes richer ore bodies along the line of the Comstock.

CHOLLAR POTOMI.—Daily yield 120 tons of ore, assay value of which is \$30 per ton. The main south drift on the fifth station level is making good headway, cutting occasional bunches of ore, but finding nothing of a permanent nature as yet.

YELLOW JACKET.—Cross-cutting and prospecting on the 1,400 and 1,540-foot levels go steadily on, with no particular change to note, except a decided and very promising improvement in the quality of the quartz found in the east cross-cut near the north line on the 1,540 foot level.

GOULD AND CURRY.—The exploring drifts on the 1,500 and 1,700-ft. levels are steadily pushed forward into the vein.

CALIFORNIA.—The connection of the north drift on the 1,300-ft. level with the south drift on the same level from the Ophir has given a splendid ventilation to the 1,300-ft. level.

SOUTH STAR.—Total depth of main shaft is 125 ft.

FLORIDA.—New shaft down 65 ft. to-day. This shaft is located 130 ft. north of the mouth of the old tunnel. It consists of three compartments, neatly timbered, and will intersect the ledge at the depth of about 350 ft., when something rich and good will be found, judging from the developments in the old tunnel.

CONSOLIDATED VIRGINIA.—On all the different levels the various ore breasts are looking remarkably well. From the 1,300-ft. level upwards, to the 1,000-ft. level, the ore stopes are yielding ore of a quality superior to the average of any heretofore extracted from these levels. The different openings in the ore body on the 1,400-ft. level, show it to be one of greater width than at any point on the level above. A portion of the ore supply for the mills is now being taken from this level. The milla are all kept steadily running, and the future prospects of the mine grow more flattering every day.

BALTIMORE CONSOLIDATED.—Sinking the main shaft is making the usual progress; the flow of water at the bottom shows no abatement whatever, continuing about the same as heretofore reported.

HALE & NORCROSS.—The main incline is sunk to within a short distance of the 2,000-ft. level station. This level will be opened early in June, and strong hopes are entertained that the ore vein will prove remunerative at that depth. On the 1,900-ft. level the ore streaks pass through by the several cross-cuts now being worked. The ore in these seams is of excellent quality, and as the work is advanced on them their extent appears greater than was at first anticipated. The continuity of these ore stratas, and the increased width and softness of the ore vein on this level, encourage the belief in the existence of an ore body in close proximity below.

NEW YORK CONSOLIDATED.—All the buildings over the hoisting works are completed, and the four new boilers which lately arrived from San Francisco are in working order; also, the two new steam pumps, used for draining the shaft, are taking out 6,000 gallons of water per hour.

SILVER HILL.—The main south drift, at the third station, is in a distance of 203 feet, in fair running ground. Cross-cutting the ledge on this level will soon be commenced.

IMPERIAL EMPIRE.—The main south drift, on the 1,850-ft. level, is still driven vigorously ahead to make connection with the north winze from the 1,700-ft. level.

DATON.—The ore breasts throughout the entire mine are looking well and yielding the usual amount of good milling ore.

KNICKERBOCKER.—The face of the west drift, at the 450-ft. level, is still in fine, lively-looking quartz of a very favorable character.

TYLER.—The northwest drift, on the second station level, is still being pushed vigorously ahead, the rock in the face blasting quite hard, causing a slow rate of progress.

LEO.—The rich ore streak in the face of the main drift still continues. It is from a foot to a foot and a half wide, and assays very high in gold. All this ore is being very carefully saved.

JULIA.—Sinking the main shaft is progressing at the rate of three feet per day.

NEVADA.—Still prospecting the ore vein to the southward, with strong indications of soon striking another ore chimney.

MCMEANS.—The main west drift is in 693 feet, the face in quartz and low grade ore.

BULLION.—The north drift on the 1,700-ft. level is being driven steadily forward through very favorably looking vein matter, showing a steady improvement as the face of the drift advances.

DANEY.—Preparations are being made to again commence sinking the shaft for another level.

SAVAGE.—The 2,000-ft. station is completed and a drift started to tap and prospect the ledge on that level.

UNION CONSOLIDATED.—The north drift on the 1,300-ft. level is making good headway, the face in favorable looking vein material.

Quicksilver Mining in San Luis Obispo County—The Josephine.

We take the following from the San Luis Obispo *Tribune*, and hope the statements made will to some extent cool the excitement of some who think every hole in the ground, with a cinnabar boulder, is a quicksilver mine:

All is not gold that glitters. Mining has its perplexing drawbacks. A great many men run mad over the mere prospect of a mine and get into it so deeply that unless it realizes their expectations they become ruined. There is not one mine in twenty that ever pays a dividend, and not one prospect in five hundred that ever turns out to be a mine. The quicksilver lodes are no exception. Cinnabar is where you find it; now you see it and now you don't see it. It does not run in regular veins. It lies in deposits to a great extent, and in finding these it requires money as well as muscle. That we have vast mines of cinnabar right here at our doors is apparent to everybody. Their richness and extent are yet to be tested, and money and time will both be required in doing it.

The Josephine.

We wish we were able to give a favorable report of this mine, but are inclined to the opinion that the company is working in the wrong hill; from the way the mine looks at present, something is the matter. The mine is located about ten miles north of Cayucos landing, near the headwaters of the Santa Rosa creek, and about twenty miles southeast of the Pine Mountain district. It is among the earliest locations in the county, and as much solid labor has been expended on it as on nearly all the others put together. It has been opened ten years. It was taken up originally by a party of Spaniards, Barron & Co., of San Francisco, purchased it soon after its discovery and have been driving work on it ever since. This Barron & Co. have been engaged in mining for twenty-five years on this coast. They have control, and have had control of the New Almaden mine for many years. They are of course, very wealthy, and able to prospect extensively. Not until three years ago were the furnaces put up. The claim, (located under the old mining laws), consists of 5,000 feet, running northeast by southwest, dipping west on an angle of forty-five degrees. It has been average width of seven feet. The lode is well defined, being bounded by serpentine and talc. The formation is favorable. The company has expended \$100,000 in testing the value of the mine. The hill has been telescoped into a honeycomb, and no very extensive veins of honey have as yet flowed from it to reward them. The longest tunnel is 600 feet in length, extending through the hardest kind of rock. Every foot has been blasted, the material being very firm and flinty. This tunnel taps the ledge at a depth of 175 feet from the surface. Another tunnel 400 feet long, another 200, and one 128 feet long, tap it at different depths and angles. The rock in some places is a talco-elate, almost impenetrable. In going through the vein matter it has cost as high as \$60 per foot to drive drifts and tunnels. It is a joint stock company, but four fifths of the stock is owned by these quicksilver kings of the bay city.

Mr. A. Dennis, a very intelligent and efficiently practical miner, is now superintendent of the works. He is very reticent concerning the prospects, and does not appear anxious to talk with a newspaper man on the subject. He has been there in charge for two or three years and has accomplished a great deal of work. There are now twenty miners at work in and about the diggings. They are taking out ore from some croppings on top and from the lower drifts. The rock shows cinnabar, but there is not enough of it. Taken as a whole, the ledge matter would not average one per cent. Pieces of the rock will go as high as fifty per cent. You can get beautiful specimens from the breast of any drift in the mine, but the average is too small to even pay for working. In quicksilver lodes generally, the little lodes or veins of metal converge toward a center, and by tracing them up one finds rich and often extensive deposits. The company has been working along in hopes of obtaining the same results here, but so far, with one or two meager exceptions, they have not been able to find any extensive pockets. The metallic feeders seem to pinch out. The ore is very much scattered. Cinnabar is found where it does not naturally belong. Here seems to be a reverse of almost anything known in the history of cinnabar deposits. Some have thought that this company is playing a little game, and trying to deceive the public; that they have a good, rich mine and are laying low in order to get hold of other mines in the vicinity. This is all bosh. They have not the mine to justify an improvement in the furnaces, even. The furnace is a small and very defective concern, being built on the old plan. Its capacity is eight tons. They use wood exclusively in heating.

The Process.

The process of reducing this ore is very simple. There are four condensers to this one. The metal is dumped in at the top. The draft from the bottom plays through the charge passing through the ore-chambers. These condensers are kept cold by the application of water. The mercurial vapor is condensed principally in the first and second chambers. If any should escape all four of the condensers it is caught in the long flue leading to the chimney. Much care should be taken lest the heat become too intense, causing the mercury to escape. Mr. Dennis does not heat to a greater

degree of temperature than 250 deg. F. In this small furnace only good ore is worked, of course, but it is large enough to reduce all the good ore they find.

It must be regarded as rather unfortunate for this district that this wealthy company has been so deceived. Between the claims on Pine Mountain and the Josephine no comparison can be made, and yet this mine will give character, in some degree, to the whole region. Enquire naturally go to the oldest mines before looking at the newer discoveries. The Josephine showed pretty well on top, so do the others, and little is known with absolute certainty of the others except what outside appearances indicate.

If this mine were as rich as even the Keystone is known to be, it would be a great blessing and would encourage the rapid development of the country.

A Tropical Scene.

Luxuriance of vegetation and an apparent stillness and calm are attributes of all tropical scenery, as most people who have seen views of places in low latitudes well remember. Those who have resided in such localities vouch for the fact that this stillness is not apparent, but real, and applies to the people as well as the country. In most tropical countries the inhabitants are comparatively indolent, and a large proportion of their time is passed in idleness. We all know that the effect of a hot day in this country on most people is to cause them to seek some shady nook where they can lie and rest, and doze away the afternoon in contented

A TROPICAL SCENE.

laziness. Those of us who have experienced these feelings will excuse in a measure, the residents of Mexico, Central America or the south sea islands for their idleness, when we remember that a tropical climate, with its many days of warm weather is likely to influence those people as warm days do us. The tropical scene shown on this page is one taken in the interior of Tahiti, and the place looks like a pleasant one to pass a few idle hours.

NEW DISCOVERY FOR MAKING STEEL.—By using from 15 to 20 per cent. of an ore lately discovered in York county, ordinary pig-iron can be converted into steel in a reverberating furnace, with the usual setting or fix used to make good wrought-iron, at a cost not much over making good iron. This ore, used with pig metal, in the proportion of one to five, has been made into steel, and from this steel rails have been made. Some of the rails made at Baltimore and placed on the Baltimore and Ohio railroad, have been down 15 months, and have worn longer than three iron rails would have done, and are yet good. Those made at Lochiel were placed at the junction of the Pennsylvania Central and Lebanon Valley roads, have been on the road over a year, and have worn longer than two iron rails. These rails have been placed, as a test, at points where rails are harder worn than any other points on these roads.

WHAT IT DOES.—Gold is the articulation of commerce. It is the most potent agent of civilization. It is gold that has lifted the nations from barbarism. It has done more to organize society, to promote industry, to inspire progress, to encourage science and the arts, than gunpowder, steam and electricity. The use of gold had its origin in the necessities of mankind. The human heart is set upon it. It will command the proper services of everybody at all times and in all places. The necessities which compel its use are as inexorable to-day as they were at the beginning. So exact a measure is it of human effort that when it is exclusively used as money it teaches the very habit of honesty. It neither deals in nor tolerates false pretenses. It cannot lie. It keeps its promises.—[Extract from speech of J. P. Jones in U. S. Senate.]

Lixiviation.

As New Mexico is greatly interested in the mining and working of precious metals, a few words upon one of the many processes of beneficiating ores may not be entirely unwelcome. We wish to call the attention to the process known as lixiviation, for the extraction of silver. This is comparatively unknown and not employed in the United States. For many years, experiments have been made by different chemists and metallurgists, in endeavoring to perfect this process sufficiently to give it a command over the present modes of working ore; yet it is but lately, within the last two or three years, that its practical working has been such as to commend it as the most profitable. In Sonora, it was developed into its present high standing; and such is the estimate placed upon it there, that most of the mills are adopting it; and all acknowledge its superiority in working ores for silver alone. Where gold is found in the ore, it is extracted by the old methods. Lixiviation steps in and takes the place of quicksilver; otherwise the milling, etc., is just the same. Plans and settlers are done away with, and with them quicksilver. For a rough outline of this method, we have the following:

The ore is dry crushed by battery and roasted in a triple furnace. The roasted ore is placed in wooden boxes (about four feet wide, two feet high and eight feet long) which have false bottoms or a frame of lattice work covered with canvas in order to retain the ore while filtration takes place. Roasting is necessary in order to obtain soluble metallic salts in the ore.

Water is now run upon the ore in the boxes; the flow of water received being equal to the discharge—keeping the box always full. The salts of the base metals being soluble in water, we find that they are decomposed and carried off by the flow of water, leaving behind the silver. After four or five hours a test is made to know whether all the base salts have passed off. The test is either made by sulphate of lime or by tasting—the water being very sweet when bearing silver. Next the flow of water is turned off and the ore allowed time to become drained—occupying about an hour. Then a solution of bluestone and salt or chloride of copper is run on, which carries off the silver, is received in large tanks (wooden) where the sulphate of silver is precipitated by a solution of sulphate of calcium. About one part of lime to two of sulphur is used in making the latter solution. The clear liquor in the precipitating tanks is now run off and pumped into the reservoirs or tanks from which it originally came, to be used again. The precipitated silver is taken and placed in canvas drains, and washed to remove the hyposulphate of lime. It is then pressed and dried in a furnace (reverberatory)—the sulphur being disengaged by the heat.

From the furnace the silver is placed in crucibles with proper fluxes. Some suppose this process to be not applicable to refractory ores; yet 82 and 83 per cent. silver are obtained from ore which has considerable galena, zinc blende, some antimony, arsenic, iron pyrites, etc. About one day is necessary in this process. The number of boxes or tanks used should be regulated by the capacity of the mill. The cheapness of the method is notable; merely lumber for the boxes; some lime and sulphur; no expense in pans; entirely avoiding the monstrous expense of quicksilver. This subject is well worthy the attention of mill men and miners, as it greatly reduces the cost of beneficiating silver ores.—*New Mexican.*

The Senate has passed a bill granting to the Sierra Iron Company the right of way through the public lands for a railroad and telegraph line. Also, the bill granting the same privilege to the American Fork Railroad Company.

MINERS continue to prospect for cinnabar in the mountain ranges in Lake county.

River Mines in Montana.

The *New North-West* says: The recent discovery of river-bed mines on the Jefferson is important. Had the deposit of gold been light it would have attracted little attention, for there is scarcely a stream in Montana whose banks or bed will not pan out "colors." But the yield has been extraordinarily rich and prospecting along a distance of 20 miles shows them to be extensive. As yet work has only been prosecuted sufficiently in one locality to give actual results, but that has paid over an ounce a day to the hand with a rocker, and prospects equally good have since been obtained in other localities. Letters and persons from that section fully sustain the newspaper reports, and the judgment of miners is that the pay is big and extensive. If these concurring testimonies are correct the value of the discovery is of vast importance to Montana—important in the employment it will give when water has slackened in the smaller streams, in the gold it will yield, in the prosperity it will give that immediate region, in the attention it will direct to Montana, in the immigration it will encourage and in the incentive it will be to prospect other rivers with the strong probability that discoveries of equal value will be made on them. All recollect the wonderful richness of the California river mines of the early day; and latterly the finest placer mines of that State are being developed in the old river channels where water has not run for ages.

When gold was discovered in Montana a little attention was given to examining the rivers, but not being rewarded with immediate and great success, and Banquo, Alder and Last Chance diverting attention, the prospecting element sped to the gulches and it seemed to be taken for granted that there was no gold in the rivers, just as it was taken for granted for years that Montana was too cold for fruits, flowers and cereals that are now being successfully grown. A few weeks ago Mr. Hedges, apparently more as a caprice than with any expectation of getting pay, happened to wash a few pans of dirt on the bank of the Jefferson, happened to do it just where paying prospects rewarded the first effort, and to-day 20 miles of the river are taken up and results obtained which justify the belief that a great mining field has been struck. For ten years there has been settlement and occupation of that valley, but evidently no one ever before thought to prospect the river.

Now, if the Jefferson, with no extensive discovered placers or gold-bearing quartz in the immediate vicinity yields thus, is it not reasonable to believe that other rivers, and especially those to which gold-bearing channels are adjacent and tributary, afford a promising field for the prospector, and that attention might be profitably turned in that direction? There is illimitable area in Montana where color is distributed through the gravel, in fact to such an extent that in many localities it requires a considerable stretch of conscience to make non-mineral affidavit to take up agricultural lands in the valleys. Without going into details outside, it is a known fact that the gravel vein underlying this town yields prospects that would pay to sluice in a surface mine, and we know of localities, owing to the terms prescribed by the Land Office, where farmers would rather have good springs than sink wells before they get their patents. With this general diffusion of gold, it is fair to infer that there are paying channels on the river levels, and not improbable that some of them are in the present beds of the streams. The matter seems to be worthy of practical investigation; the field looks more inviting than the high gulches, for sufficient expense and inconvenience and impossibility have been experienced on account of cost, scarcity or lack of water in gulch mining to even render desirable diggings that require the turning of a river from its channel. That the Jefferson mines will pay and pay enormously perhaps before that can be demonstrated but it will be at a time when water will be comparatively exhausted elsewhere, and if they do pay the legitimate sequence of it will be the exploration of the other rivers of Montana, and we trust equally valuable results.

DISASTROUS MINING VENTURE.—The Eclipse gold mine, near Independence, Inyo county, was purchased and opened last year by an English company, who sent out an inexperienced officer to superintend the work. After an expenditure of \$720,000, with no actual or immediate prospective returns, the enterprise of the company subsided. Mr. Willett, a director of the company, has just been making an investigation of affairs, and started on his return to London by the overland train this morning, intending to return in November to reinaugurate active operations. The property includes a 30-stamp mill, and machinery valued at \$100,000. A shaft has been sunk 350 feet, and there are 20,000 tons of ore in sight, estimated to yield \$20 to the ton. Mr. Willett reports gross mismanagement in the working of the mine, and it is his expectation that a new company will be organized to take the enterprise in hand.

PRODUCTION OF LIGHT IN STONES.—When various kinds of hard stones are pressed by the workmen (with their hands) against quickly revolving grindstones, the transparent stones become pervaded throughout with a yellowish-red light, like that of red hot iron. Opaque stones give a red light, at the place of contact, with halo and epaulettes. Dr. Noggerath thinks the phenomenon worth studying by physicists.

USEFUL INFORMATION.

Testing for Metallic Poisons.

When food, portions of the body, or the contents of the stomach, are to be analyzed for the purpose of proving the presence or absence of metallic poisons, the first and most difficult part of this operation is the destruction of the organic matter without expelling the poison. Verriken proposes to accomplish this by oxidizing it in a combustion tube. Oxygen gas is purified by passing it through sulphuric acid and cotton or asbestos, and then conducted through the ordinary combustion tube containing the suspected substance. The tube is heated intensely throughout its whole length, except where the organic matter is placed, and the current of oxygen so regulated that the substance shall not take fire, and that no particles of matter are carried off by the gas. After burning, the tube is rinsed with boiling nitric acid, and then with boiling water. This liquid is clear and colorless, and can be used for making all the tests. Experiments made by Verriken prove that this method is delicate and satisfactory. In using the Marsh test for arsenic and antimony, the same chemist advises the use of a three-necked bottle as a generator, one neck being provided with a delivery tube, another with a funnel tube as usual, while the third allows a current of pure hydrogen to be passed into this generator from a gasometer. The advantage of this arrangement is that it permits a flame of the desired size to be kept up uninterruptedly as long as may be necessary.—*Journal of Ap. Chemistry.*

The immense trade in Australian canneds meats, now carried on, has had the effect of causing a great accumulation of bones in Melbourne, where this putting up is done. The sale of these bones is now growing into a remunerative branch of export trade as bone-dust manure, and an Australian paper, speaking of this subject, gives an account of the manner of its exportation. It says that a recent vessel, bound for London, had on board a shipment of 100 tons of bone-dust, prepared for exportation in an altogether novel manner, and one which promises to come into extensive use. To facilitate this trade, an apparatus has been contrived for compressing bone-dust into half its original compass, reducing it at the same time into a form very convenient for shipment. By means of strong pressure the crushed bones are moulded into cakes of 6 in. square and 3 in. thick, something like flooring tiles, each cake weighing a little over 4 lb. These bone-dust tiles are just adhesives enough to admit their being handled freely—thrown about like bricks, if necessary—and are yet firm, and when required for use they can readily be crushed or melted by this application of a little hot water. A ton weight of the manure measures 26 cubic feet, and contains 252 of the cakes.

PREVENTING INCrustATION IN BOILERS.—A patent was recently obtained by E. Field, London, England, for preventing incrustation in boilers. This first part of this invention consists in preventing or counteracting incrustation by the use or employment, within this boiler or heating vessel, of a piece or pieces of metal electro-negative to the metal of this boiler or heating vessel, such electro-negative metal being submerged or immersed in this water or liquid within the boiler or heating vessel, and connected to the metal forming the shell or body of the boiler or heating vessel by a suitable conducting wire or connection or connections, in such manner as to establish and maintain a voltaic current or currents from the shell or body of the boiler toward the submerged or immersed piece or pieces of electro-negative metal, a clean surface being maintained upon the said piece or pieces of electro-negative metal by the use in conjunction therewith of a loose or movable piece or pieces, or terminal or terminals, or cleaning device.

A SPRUCE CONE.—One of the prettiest objects I ever beheld is a spruce cone, filled with sand and grass-seed, which sprouted and grew out of the scales. It is now as large as a cocoanut with the husk on, and of the most vivid green color. The grass grows with a luxuriance that is remarkable. To produce this charming specimen, the cone was baked in a stove oven till the scales opened out equally. It was then carefully filled with equal parts of sand and grass-seed, a string tied to the top, and the whole suspended in the dark, in a jar, with water enough to come half way over the cone. In a week it was placed in the sunlight, when the seed sprouted rapidly, and in a month filled a gallon jar completely. It has been taken out and hung in the window exposed to the air of the room. Every morning it is thoroughly soaked in milk-warm water.—*N. Y. Tribune.*

IMPROVED MUCILAGE.—Ordinary mucilage, made from gum Arabic, does not fix paper to wood or pasteboard, or to metallic surfaces. These disadvantages are overcome by adding a solution of sulphate of aluminum, in ten times its quantity of water. Ten grains of aluminum sulphate are sufficient for 250 grains of mucilage. Prepared in this way it will not become mouldy. Again, according to Hirschberg, a few drops of strong sulphuric acid are added to the gum solution, and the precipitated sulphate of lime allowed to settle. Solutions prepared in this way a year and a half ago have neither become mouldy nor lost their adhesive power.—*Four. of Chem.*

TO DETERMINE THE HEIGHT OF WATER FALL ON A RUNNING STREAM.—According to Craik, the best method is as follows: The method is only applicable to still water with running streams. This must be obtained by making a small temporary dam, unless natural dams exist, which give a sufficiently still surface. Take two poles of sufficient length to reach from the bottom of the water to the height of required line level. Measure these poles from the upper end down to the length intended to stand above the water, and make a plain notch or mark upon both sticks at this point, by laying both together, to insure perfect equality of height. These may be marked in feet and inches, for convenience in showing or in varying this line of level. Now point or sharpen the lower ends of the poles, and stick them down through the water into the earth at the bottom, until the notch marks are both at the level surface of the water, taking care to have them stand plumb, and in the right lines, and at a convenient distance apart; then sight across the top of these two, and set a third rod fourth, or any number required to run this line of level to the desired point, ranging the tops accurately by this first two, and the tops of these poles will show a water level so many feet above that of the water from which it is taken. The author above referred to, maintains that this is a more accurate way than this use of an ordinary spirit level.

HARD LIME FLOORS.—It is said that the Mexicans make a floor on which a horse can trot without making an indentation, by the following method: A layer of broken limestone, three or four inches thick is laid evenly over the surface of the ground, and over this is spread to the thickness of two inches, a mortar composed of two parts sand to one of lime; this is allowed to stand twenty-four hours, or until the surface becomes quite dry. The floor is then thoroughly pounded all over, until it becomes as moist as when first laid, with a block of wood about a foot square and three inches thick, having a handle rising from the middle. The floor then dries, and this operation is repeated until very little moisture can be brought to the surface; a thin layer of red ochre is then sifted on. The floor is then thoroughly polished by a smooth, flat, water-worn stone. Roofs are made in the same manner, without the coloring matter, which is added merely to improve the tint, and they are unaffected by sun or rain.

NEW IMITATION MARBLE.—A new process is now employed for making slate assume the appearance of marble, for decorating interiors. After being properly cut and trimmed, it is scoured with pumice stone, then rubbed with powdered pumice stone and polished with felt. It is now ready to be transformed into marble. The slabs having been painted with the ground-work color, are ready to dip. A vat, containing water mixed with ox gall, on which the colors are floated, is at hand. A brush is dipped in the color and sprinkled on the surface, then the water is fanned with a palm leaf, and the brush drawn through several times. The mixed paint spreads on the surface of the water like veining in marble, and the slab is then lowered until it touches the surface, when the floating color adheres to it; it is then put to dry. After the application of colors, sundry bakings and polishings finish the work. This marbled slate is quite elegant, possessing sixteen times the strength of marbles, and scarcely distinguishable from it.

The continual rise of some lands, as Sweden and Norway, long since observed, has been found to extend to all the land around the north pole, and even evidences show that the rise is more rapid in proportion as we come nearer to the pole. Sir Charles Lyell found by careful gauging that while the rise is very slight in the south of Sweden, it amounts to four feet in a century in the northern parts of Norway. Further, the seal fishers testify that the sea bottom rises so much in Spitzbergen and the Polar sea of Siberia as to exclude this whale, which in their memory was abundant there in deep waters, and which now are shallow.

A CEMENT TO STOP CRACKS IN GLASS VESSELS TO RESIST MOISTURE AND HEAT.—Dissolve cassine in cold saturated solution of borax, and with this solution paste strips of hog's or bullock's bladder (softened in water) on the cracks of glass, and dry at a gentle heat; if the vessel is to be heated, coat the bladder on the outside, before it has become quite dry, with a paste of a rather concentrated solution of silicate of soda and quicklime or plaster of Paris.

SOLDER FOR UNITING BRASS AND STEEL.—This difficulty of fusing a material suitable for permanently joining brass with steel or iron, on account of the unequal expansion of the two metals, is well known, on which account it may be of service to note that Dr. Dingler recommends the following alloy possessing the properties necessary to insure a permanent adhesion: tin, 3 parts; copper, 39½ parts; and zinc, 7½ parts.

IMITATION OF TORTOISE SHELL.—A mixture of equal quantities of glue, lime and red lead, with strong soap lyes, is used to attain horn in imitation of tortoise shell. The mixture may be laid on with a brush. It requires a little skill to lay it on in such a way as to make the mottling appear natural. The operation should be repeated two or three times, each time allowing the mixture to dry before another application.—*Artisan.*

Good Health.

Principles of Ventilation.

Lewis Leeds says, in the *Sanitarian*: Ventilation is based upon the movements of air at different temperatures, but we cannot get rid of foul air, or supply fresh air in the same manner as we would free a house of foul water or supply it with that which is pure by exact measures, allowing just so many cubic inches for each occupant.

The conditions are entirely different. In studying the movements of the air, if we would compare them with the movements of water, we must imagine ourselves at the bottom of the ocean with the ground underneath us heated as a fire would heat the bottom of a pot. By watching the motion of the water in a glass globe with a fire under it we can form some idea of the immense agitation of the external atmosphere.

Inaccurate, unscientific, and even repulsive as the idea may be to the mathematical mind of the architect, that we should depend in a great measure upon this mere agitation or the mixing up of the fresh and foul air, for our chances of getting pure air, I think, notwithstanding, this is just what we have to submit to. This is what nature teaches us, and although we may be to a certain extent artificial beings, and live in artificial houses, half of a lifetime spent in trying to work in a more precise and accurate manner than Old Madame Nature does, has about worn out my patience in that direction; and I confess that her hurly-burly way of mixing the oxygen, nitrogen, hydrogen and carbonic acid, and all other gases together in one grand mass, and scattering them around promiscuously, is better than any arrangement I have ever been able to devise. The more we study the subject the more evident it becomes that agitation is the natural method of ventilation—it is Nature's great purifier.

Now, if we accept agitation as the true principle of ventilation, we find ourselves far more likely to get our share of pure air by it than by the mathematical cubic-inch programmes. Nature does not do us out pure air by the cubic inch, but if unrestrained, supplies every living thing abundantly. She scorns every attempt to measure it, and if we adopt her method of warming, it will be about as easy to supply a hundred cubic feet of cold invigorating air per minute to every individual, as we now find it to be to dole out a pittance of ten cubic feet per minute of warmed, debilitating, nauseating, hot air. I have spent a great deal of time and money in getting up patterns and taking out patents for warming contrivances. But I have done with them. We have been running air-heating to such extremes that I have become perfectly disgusted with it. If we inhale air at the same temperature as the blood it quickly kills us. Nature never ruins the air for breathing purposes by overheating it—she leaves such miserable business to the managers and warmers of railroad cars, asylums, hospitals, and not unfrequently, our homes.

Agreeable Emotions and Health.

Professor Tyndall while in this country last year visited the Falls of Niagara, and on reaching the Caves of the Winds by descending Biddis's stairs he conceived the idea of attempting to pass under the blue waters of Horseshoe Falls from that point. He found a guide who was willing to make the attempt with him, and together the next day they passed through the mist and foam of the roaring cataract, reached the desired point, and returned in safety. In describing his emotions at one point in his perilous journey, he remarks as follows:

Here my guide sheltered me again and desired me to look up; I did so, and could see as before, the green gleam of the mighty curve sweeping over the upper ledge, and the fitful plunge of the water as the spray between us and it alternately gathered and disappeared. An eminent friend of mine often speaks to me of the mistake of those physicians who regard man's ailments as purely chemical, to be met by chemical remedies only. He contends for the psychological element of cure. By agreeable emotions nervous currents are liberated which stimulate blood, brain and viscera. The influence rained from ladies' eyes enables my friend to thrive on dishes which would kill him if eaten alone. A sanative effect of the same order I experienced amid the spray and thunder of Niagara. Quickened by the emotions there aroused this blood sped healthily through the arteries, abolishing introspection, clearing the heart of all bitterness, and enabling one to think with tolerance, if not with tenderness, of the most relentless and unreasonable foe. Apart from its scientific value and purely as a moral agent, this play, I submit, is worth the candle.

ECONOMY OF ANIMAL HEAT.—Professors Voit, Recknagel and Pottenkoffer are just now occupied in investigating the economy of animal heat, and have found that after six hours' hard work the person leaves the apparatus in a cooler condition than when he went in, or after he had been at rest in the apparatus for the same space of time. Of course the ventilation of the apparatus must work well and send per hour about 11,100 gallons, or 1,800 cubic feet of air through the chamber, else less water and less heat depart by evaporation.

The Suppressed Member Again.

Not long since we noticed some of the natural evils resulting from the customary repression of the left hand, and advocated, on physical grounds, its culture equally with that of the right hand. It seems that there are not less cogent mental reasons for developing the two sides of the body impartially.

It is coming to be well known that mental development is the result of properly directed physical training; that this brain grows in size and power by this varied exercise of the senses and the will in mechanical employments quite as rapidly as by purely intellectual efforts in study or otherwise. It is squally known to physiologists that most men are one-sided in heads as in their bodies. The two halves of the brain are rarely developed symmetrically, as may be readily seen in the "conforms" or head measures accumulated by hat-makers applying individual customers. To some extent, the difference in the contour of the two sides of the head may be due to unequal pressure on the nurse's arm, or to the habit of lying chiefly on the one side while sleeping, thus causing a permanent displacement of the walls of the skull; but the main reason appears to be our one-sided habit in education.

Dr. Brown Sequard observes that the study of the facts relating to the brain has led him to believe that "each half of the brain—paradoxical as it may seem—is a whole brain," each lobe being normally competent to perform all the functions of both, not so vigorously, of course, as the two acting together, yet with apparent completeness. Unfortunately, however, the most of us are single brained, as we are single handed, and for the same reason. We fail to do what is really needed to give us two working brains. "There is no question," concludes this skillful observer, "that it is our habit of making use of only one side of this body that consigns to one-half of the brain—the right side—the faculty of expressing ideas by speech. If we developed both sides of our body equally, not only would there be a benefit that we would write or work with this left hand as well as with the right, but we should have two brains, instead of one, and would not be deprived of the power of speech through disease of one side of the brain."—*Scientific Am.*

Moist and Dry Air.

A comparison of the losses of heat by the respiration of an absolutely dry and absolutely saturated air at 32° and 86° F. is highly instructive. At 32° and dry we lose 1,172 caloric units; at 86° and dry we lose 1,096 caloric units—difference only 76 caloric units. At 32° and saturated we lose 1,060 caloric units; at 86° and saturated, 420 caloric units—difference as much as 640 caloric units.

The different states of dryness of the air appear thus to be of a greater moment than the difference of temperatures, and this is the reason why our sensations do not always coincide with the thermometer. You readily understand how much more difficult it is to manage one's heat-household in a hot than in a cold climate. Our means of warming ourselves are better than those for carrying off our heat. Therefore the European races has had a hard fight under the equator. The working power of the body depends upon a certain amount of consumption, by which a certain amount of heat is necessarily created, which has to leave this body in a regular way. This Hindoo who has to draw the European's plank, bears the heat better in proportion as he takes less food and creates less heat in himself, but then his working power is quite proportionate to the total of his consumption.

The European's struggle in a hot climate and his dangers of a degeneracy will remain as long as he has no better means of cooling himself by some or all of the known three routes. Houses with thick stone walls are tolerably efficacious. These walls rarely get warmer than the average temperature of the year. They cool the air which comes into the house, and act on the inmates in the way we have seen when speaking of the room which is not warmed through and through. A good means would be some contrivance by which the air in the house could be deprived of water.—*Pettenkoffer.*

DYSPEPSIA REMEDY.—The following remedy for dyspepsia is said to be very effective in some cases: "Sweet cream or sweet milk, the richer the better; use as often as convenient. Whenever any burning or sour sensation at the stomach appears, drink half a pint of sweet cream or milk, and relief is evident. Make free use of it at meals. Total abstinence from the use of tobacco, coffee, strong drink, or anything very sour, must be strictly adhered to. Coffee being the worst of all things for dyspeptics must be entirely avoided." Dyspeptics should also remember that as their troubles come from over-eating, or eating irregularly, or some abuse of the stomach, the matter of a limited diet of nourishing food, taken regularly, is quite as important as anything in the shape of medicines.—*Herald of Health.*

Rest, content, peace, such words as these belong not in our vocabulary; we retain them, indeed, in our dictionaries as mementoes of what were once the possession of our fathers on the far side of the water; but the sweet thoughts for which they stand, like some timorous bird that has wandered from its native zone, fluttered and startled by our fretful turmoil, have spread their pinions and flown back to their original seats.

Society of Engineers of California.

The regular monthly meeting of the Society of Engineers of California was held on Monday evening last at their rooms in the Mechanics' Institute building. The members present were W. A. Goodyear, J. Birmingham, J. R. Smedberg, George W. Dickie, James Spiers, David Stoddart, W. A. Phillips, Samuel H. Wheeler and W. J. Lewis. There were about 40 guests present. The meeting was called to order by W. A. Goodyear, Vice-President. Minutes of previous meeting were read and approved.

Mr. Smedberg announced that he would read before the meeting of July 7th, his paper "On True Condensation, based upon the Vesicular Theory of Vapors. No subsequent papers were announced other than those previously spoken of. These are "On Quartz Mining Machinery," by Irving M. Scott, of the Union Iron Works; "On Submarine Exploration," by C. H. Longee.

Candidates for membership were notified that proposal forms may be obtained from the Secretary at any time after June 10th, and that the names of candidates must be sent in by June 25th. Messrs. Spiers and Lewis were requested to forward the papers read by them, to the managers, who will decide as to their publication. Notice was given that the inaugural address by the President, G. F. Allard, would be published in the SCIENTIFIC PRESS of June 6th, and that members could obtain copies from the Secretary.

Mr. G. W. Dickie, mechanical engineer, read an interesting paper "On Compound Engines," after which some discussion ensued, in which Messrs. Dickie, Spiers, Phillips, and Smedberg took part.

On motion of Mr. Spiers, seconded by Mr. Phillips, the thanks of the society were voted to Mr. Dickie for his valuable paper.

If possible we will obtain Mr. Dickie's paper and publish it in a future issue of the PRESS.

Mining Affairs in Trinity County.

Never has the business of mining been more active or prosperous in this county than at the present time. With minea less depleted than in most parts of the State, with water in full supply, and many claims better outfitted than ever before, there will be more gold dust gathered this year, for the number of hands employed, than during any other season in the history of the county. It is true this money is not now distributed amongst so large a number of persons as was formerly the case; the minea, aggregated into extensive claims and owned by fewer men, being now operated by means that largely supersede the use of manual labor. This aggregating process has not, however, been carried in Trinity to the extent practiced in the more central and southerly counties; wherefore, they have still a numerous, self-employing population, insuring for the product of the placera a wider diffusion than is common elsewhere. Already the animating effects of the gold harvest the miners are beginning to gather are being felt in other branches of business, old scores having been paid off or assurance given of their early liquidation. Money matters are getting easy all round. The merchants have already replenished their stores, getting in their goods earlier than usual. Much building is going on in Weaverville, and a variety of improvements are in progress elsewhere throughout the county.

Mining Properties Sold and New Enterprises Inaugurated.

Several heavy mining enterprises have this spring been set on foot, and the sale of some gravel ground and water rights consummated. Among the latter is the McGillivray estate, situated 15 miles below Weaverville, on the main Trinity. This consists of extensive river bars, farming lands, highly improved, water franchises, ditches, etc.; and, if bought for the sum reported (\$130,000), was got at a bargain, as the clean-up of the present season is estimated at \$75,000, two thirds of it net profit, and this production could, without any very great expenditure, be nearly doubled. A similar estate, belonging to Dr. Waite, located one mile above Weaverville, has also been disposed of this spring, the purchasers being mostly resident miners. A ditch has recently been completed carrying a portion of the water appurtenant to this estate, upon Oregon Gulch mountain, where it is now being used for piping off a deposit of rich gravel owned by the company. This ditch, which is four miles long and carries 2,500 inches of water, has been built during the past three months; a feat that speaks well for the energy of the builders, the weather having been much of the time very unfavorable for out door operations. It is believed that the clean-ups of this company will exceed anything ever before made in that section of the country for the quantity of water run.

A sale of the estate belonging to the Stewart's Fork and Buckeye Hill Water and Mining Company is said to have just been effected to parties in San Francisco. The price paid for this estate has not transpired. What do our readers think of 5,000 inches of water, increased at times to 10,000, played under any pressure desired, upon a thousand acre tract of friable gravel, having an average depth of 800 feet, free from every manner of obstruction, with ample fall for tailings and composed of pay material throughout? And yet such are the conditions of this deposit; nor will the cost of conducting the water upon, and outfitting this ground be large, as the former can be accomplished through the construction of a ditch less than 20 miles long, traversing a country of the most favorable kind, while the deep ravines that border or intersect the tract furnish natural faces and outlets on every hand. The purchasers, it is said, will proceed with diligence to put this property in shape for productive operations, and if wisely handled something immense may be expected to result from the enterprise in good time. At least a dozen of eels of less importance were effected here within the past six weeks, showing an active condition of the mining estate market. The advent of strangers, seeking good opportunities for investing in this class of property, is noticeable, and there is little doubt but many more sales will be made before the season is over.

The Davidson Flume.

Besides the outfitting and starting up of work on many new mines, it is gratifying to have reason to record a great improvement in the prospects of an old and extensive project, in the success of which the residents of Weaverville and the mine owners about it are deeply interested. We allude to the Davidson flume, a large and costly structure laid down along Weaver creek for the purpose of running off and discharging into Trinity river the tailings that for more than twenty years have been collecting in Weaver basin, and which have so accumulated as to seriously interfere with mining operations there. Nearly a mile of this flume has been completed, at a cost of about \$30,000, leaving five miles yet to be built. It is 16 feet wide and 12 feet high, constructed of heavy lumber and anchored with iron bolts into the bed-rock. The winter before last being dry, there was not enough water to carry off any great amount of tailings, and it was feared the work would prove a failure. With the present abundance of water, however, it is accomplishing a great deal of good, relieving many of the overcharged claims,

and promising the proprietors a rich harvest of gold. This structure is divided into two compartments, the one ten and the other six feet wide. When there is plenty of water both are kept running at the same time. When the water diminishes it is all turned into one, and the other cleaned up. This operation will not be performed the present season until July, when the prospects, some of which run as high as an ounce to the pan, indicate a capital result.

The final success of this flume should encourage the projectors of these tailing operations elsewhere in the State to perseverance, as only a bountiful supply of water seems necessary to insure good results; and this can in most cases be readily commanded. If \$40,000 or \$50,000 and, possibly, \$60,000 or \$80,000, can be extracted from these tailings in the course of three or four months, worked on such a comparatively limited scale, what may be expected from the steady operations of an enterprise like that designed to re-wash the tailings of Bear river?

From 1851 to 1858 Trinity county had a population of working miners of about 4,000, whose earnings aggregated scarcely \$2,000,000 per year. The miners now there do not exceed one-third of that number, and yet it is estimated that their gross earnings will this year amount to more than a million dollars, and may even reach a million and a quarter, making yearly average wages of nearly nine hundred dollars to the men; while it can hardly be said that they work more than half, certainly not over two-thirds, of the time.

The Cienega Placers.

A company has recently been formed in this city to work the placer mines of La Cienega and Los Llanos, in Altar District, State of Sonora, Mexico. These mines will very shortly be opened and worked in accordance with the method employed in the California gravel mines. We have seen some specimens of coarse heavy gold from these mines, obtained a short time since by "dry washing." The property is 60 miles east of the port of Libertad, on the Gulf of California, and comprises 132,880 acres, for which the company recently formed have secured the Government title, including all the wood and water rights.

These placers were discovered 80 years ago, and for a period of 30 years were worked by the dry method, and are said to have produced fabulous amounts in this rude way. They have not been worked for 50 years; but parties in the interest of the company recently examined the ground, and report that nearly every portion of the placers will give a heavy yield, which with water may be materially increased. The ground to the bed rock gives an average depth of from 10 to 50 feet. The earth is a sandy loam, containing a great deal of decomposed quartz, mica, and black oxide, with gravel sufficient to facilitate washing. There is a splendid fall from the placers, but unfortunately the nearest water is all below the placers, and will have to be forced up to where it is to be used. The company are now purchasing the necessary machinery, pumps, pipes, lumber and supplies for operating six lines of sluices on the ground of La Cienega, with a view of further extending their works, and carrying them to the adjoining placers of Los Llanos.

Capt. Samuel Tyler, the Superintendent of the company, a gentleman well known in mining circles on this coast, recently visited the property, and is very enthusiastic and hopeful on the subject. He says he can get all the hende he wants for fifty cents a day, and that when he once has the water on the tract, he expects to surprise even those well acquainted with the richness of some of the richest of California hydraulic minea. The fact that the mines have been so productive when worked by a rude "dry process," encourages him to look for a marvelous yield when he has a supply of water. With the proper machinery and appliances he apprehends no difficulty in supplying the land with an abundance of water, after which he has no fear for the result.

The Kohler Reduction Works formally opened their offices in this city this week. The company have purchased Damon's Landing, six miles south-east of Oakland, on which to erect buildings. A switch track will be run from Oakland, and a station erected at the works. Some 40 or more laborers are now at work on the ground, and by September everything will be ready for the reduction of ores. It is estimated that the cost of putting the works in operation amounts to \$150,000; over \$30,000 having already been expended. We will shortly have a detailed description of these works and the manner of operating. The company propose to purchase ore and work it themselves, doing no custom work.

COMMISSIONER Drummond, of the General Land Office, formally gave up his office to his successor, Mr. Burdett, on the 1st inst. How rejoiced he must be in being able to get away from that interminable mining law. He has spent so many years explaining to the people what the law means, that we should think he would immediately commence earnestly to forget everything he knows about it, in order to relieve his mind. We shall miss his signature to the frequent "mining decisions" issued from the Land Office, and hope that he will no longer be harassed by inquisitive miners and lawyers to learn his construction of the law.

Placer Mines Exempt From Annual Expenditure.

There has been some indecision among our placer miners as to whether the placer mines were affected by the section of the Law of May 10th, 1872, which provides for an annual expenditure in order to hold claims. In some localities the work has been done on gravel claims for fear that the Law required work to be done on them as well as on quartz. In response to an inquiry from owners of placer ground in Nevada county, the Acting Commissioner of the General Land Office has given it as his opinion that gravel mines are not affected by the 5th Section of the new Law. Although, as elsewhere mentioned, the time for the first annual expenditure has been extended, owners of placer ground will feel relieved to know that they are exempt. The opinion or decision is as follows:

DEPARTMENT OF THE INTERIOR,
GENERAL LAND OFFICE,
WASHINGTON, D. C., April 25th, 1874.

DEAR SIR:—In your letter of the 31st ultimo, you inquire whether or not the mining acts of Congress require certain annual expenditures upon placer mines to entitle parties to hold the same.

In reply I would state that the first general act of Congress regulating the disposal of mineral lands, was that of July 26th, 1836, which only applied to veins or lodes of quartz or other rock in place bearing gold, silver, cinnabar or copper. The Act of July 26th, 1866, was amended by Act of July 9th, 1870, and provision made for the disposal of "claims usually called 'placers,' including all forms of deposit, excepting veins of quartz or other rock in place."

Neither of these acts prescribed the amount of work or expenditures which should be made annually upon mining claims, to enable parties to hold the same, but left this matter to be determined by the local laws, rules, regulations and customs.

The Act of May 10, 1872, repealed certain portions of the mining acts then in force, and among other things prescribed a new mode of procedure for obtaining patents to mining claims.

The fifth section of the act last referred to, provides that the "miners of each mining district may make rules and regulations not in conflict with the laws of the United States or with the laws of State or Territory in which the district is situated, governing the location, manner of recording, amount of work necessary to hold possession of a mining claim subject to the following requirements:—"

"On each claim located after the passage of this act, and until a patent has been issued therefor, not less than one hundred dollars' worth of labor shall be performed or improvement made during each year. On all claims located prior to the passage of this act, ten dollars' worth of labor shall be performed or improvement made each year, for each one hundred feet in length, along the vein until a patent shall have been issued therefor."

The only reference made to the subject of annual expenditures upon mining claims, is found in said 5th section, which provides that on each claim located since May 10th, 1872, one hundred dollars shall be annually expended, and on all claims located prior to said date, ten dollars' worth of labor shall be performed, or improvements made each year, for each one hundred feet in length along the vein.

The 10th section of said Act of May 10, 1872, provides that the Act of July 9th, 1870, "shall be and remain in full force except so to the proceedings to obtain a patent, which shall be similar to the proceedings prescribed in sections six and seven of this act for obtaining patents to vein or lode claims."

The 10th section taken into connection with the 5th section of the Act of May 10th, 1872, makes it clear to my mind that it was the intention of Congress to require annual expenditures only upon veins or lode claims, leaving placer claims as they had been previous to the passage of said act, subject to the operation of the local laws, rules, regulations and customs.

Very respectfully your obedient servant,
W. W. CURTIS,
Acting Commissioner.

The Railroad Companies and the Centennial Exposition.

The Central Pacific and Southern Pacific Railroad Companies have instructed their agents to forward free such articles or samples as they may collect on this coast, for the coming Centennial Exhibition at Philadelphia, in 1876. As showing what these companies propose doing in regard to the Exhibition, we append the following circular, which has been handed to us for publication and which explains itself:

LAND OFFICE
C. P. and S. P. R. R. COMPANIES,
SAN FRANCISCO.

The Land Department of the Central and Southern Pacific Railroad Companies is preparing to place on exhibition at the Philadelphia Centennial Exposition, specimens that will illustrate the products of the railroad land and other lands on this Coast. Agents for the company are requested to forward such specimens as they can conveniently obtain.

Contributions from farmers, mine superintendents, and others will be gladly received; and due credit will be given for all articles so furnished, which are placed on exhibition. Samples of articles enumerated below will be of especial interest.

Grains of all kinds; both the kernel, and the sheaf with stalks of full length, including roots. Fruits of all kinds, fresh, preserved in alcohol, or dried. All kinds of vegetables will be required in due time, of the crop of 1874. Almonds, walnuts, etc., giving size of the tree, and kind of soil. Oats, beans, and olives; with specimens of the oils. Hemp, cotton, ramie, soap root and jute. Tobacco and hops. Wool, goats' hair, furs and skins. Specimens of soil; with the description of the locality from which they were taken; and remarks on their adaptability to different products.

Minerals, ores, coal, peat, clay, borax, salt, etc. Building stones, brick, cement, etc. Samples of wood of native growth, in the rough or manufactured. Wines, brandies, etc. Shells, fossils and antiquities.

All specimens should be marked with the name of the locality, and full address of the donor; and should be accompanied if possible by a short description. It would be of especial interest if with specimens of grain or other agricultural products, there be sent a description of the kind of soil where the same was grown, the mode of cultivation, the time of planting and harvesting, the yield per acre, etc.

The co-operation of all who feel interested in making a successful exhibition of this kind is respectfully requested.
B. B. RENDING, Land Agent.

NOTICE.—The attention of agents is called to the above circular, and their co-operation in the objects set forth is expected. They are hereby authorized to forward free such articles or samples as they may collect, consigning the same to C. P. R. R. Co., care B. B. Rending, Land Agent, San Francisco.
A. N. Towne, General Supt.

The Emma Mine.

We have received the Annual Report of the famous Emma mine, Little Cottonwood Cañon, Utah, which, although it contains many discouraging statements, is an interesting document. The report was presented at the meeting of the company held in London, on the 15th ult., but no report of the meeting has yet come to hand. We condense from the report the following items of general interest, reserving for another issue the remarks of the managers on the concentrating works and the geological features of the mine:

The directors in presenting their accounts for the past year, express regret at their unsatisfactory character. The accounts show that an enormous outlay was necessary on the mine; the ore production has been smaller and the ore account shows only a surplus of £17,000. The directors believe that Mr. Attwood's services have been of great value to the company, and they have confidence in his management. By adopting a

system of ore dressing, arranged by himself, he has utilized the ore on the second-class dump, as detailed in his report, and the directors propose that he should return to carry out the suggestions he has made; and they also are of the opinion that so long as the mine yields sufficient money to pay the costs, the only course which gives any chance of retrieval is to push explorations.

The agent, George Attwood, reports that in the mine a large amount of work has been done during the past 12 months, and explorations have been carried on in many directions with the utmost possible speed, and at the same time under great disadvantages. I have had to contend against a heavy influx of water, with the most imperfect appliances, in the shape of pumping machinery, and I had to re-timber nearly all the most important portions of the mine, owing chiefly to former defective timbering, etc., therefore the explorations have not been as extensive as they would have been under more favorable conditions. Notwithstanding the above drawbacks I have run about 1,000 ft. in length of drifts and cross-cuts, and also sunk in shafts and winzes, etc., about 500 ft., besides carrying on the stopes and other ordinary work connected with the mine during the past year. The engine-shaft has been sunk to a depth of 60 ft. on the angle below level No. 4, and for the last 40 ft. it is in hard limestone, and shows no ore. Explorations have been made on all sides of the ore deposit, and the extent and results of the same have been reported regularly in my daily letters to your secretary. I, therefore, consider it unnecessary to reiterate the full details of the same, but merely state that the results of all exploring work done during the past year, and extending to the present time, have proved most unsatisfactory as regards the future prospects of the mine.

Mr. Attwood then goes on to say that in the center of the ore deposit cut in level No. 4, a winze has been sunk to the depth of 95 feet vertical, or about 120 feet on the angle, and called the Attwood winze. The lower portion of the above winze has now been sunk about 50 feet in limestone, all ore having disappeared in the bottom and sides of same. By referring to the accompanying figure the situation of the winze is shown. The figures also show the size and shape of the great ore body of the Emma. It will be seen that the ore deposit is surrounded on all sides by "limestone," and especially so in the bottom of the lowest workings. I have run numerous small "drifts" and "cross-cuts" which are not yet marked on the maps before you, but the results have nearly always turned out the same; that is, we have run into hard limestone showing no ore. Several "cross-cuts" made in the hanging wall above level No. 1, and below the same as deep as level No. 3, have offered a fair supply of ore, and by a most careful selection have been mined to a good profit.

I found it impossible to sink on your mine under the above conditions; and to construct a Cornish mining pump of sufficient capacity would have entailed a heavy expenditure of money—say £30,000, and which sum the mine could ill afford to pay. I met the difficulty by constructing a new mining pump, the invention

of Mr. W. J. Silver (of Salt Lake) and myself, which combines the essential qualifications of a Cornish as well as the most improved steam mining pumps, with other new improvements, consisting of rotary valves adjustable to any angle, and at the same time so constructed that mud, sand and gravel do not interfere with its successful working. The pump can also be lowered in a few moments, and the valves changed to work at any required angle. The pump now in use performs the work of a Cornish 6-inch pump, and cost, made in Salt

the mine, which, after concentration, ought to yield about 400 tons of ore, assaying (say) 35 per cent. lead and 70 ozs. of silver to the ton, and, with what you have now on the dump, ought to supply your concentrating works all this summer. The estimated quantity of mine fillings extracted during the last four months, and now on the dump ready for concentration, will foot up about 1,500 tons, and will probably yield about 120 tons of concentrated ore, assaying about 35 per cent. lead and 70 ozs. per ton in silver. The quantity and value of ore re-

weather permitted I constructed concentration works on a new plan of my own, built water ditches, sluices, etc., to apply the same, all of which work was done in a very short space of time, and at a very small outlay of money, and has afforded most satisfactory results and paid large profits.

In regard to finances the manager says: In selling your ores I have found that American smelting companies have given a much better price (even for high grade ores) than could be obtained by shipping them to England and then selling; and all sales for the past year have consequently been made to smelters in America. The full details of the same you have been regularly advised. The net return resulting from the working of your mine from March 1873, to March 1874, (that is during my time of management), may be considered to be at least \$131,000, after paying all expenses, also paying numerous old debts, one of the principal of the latter being a county tax bill of \$10,000, and that long overdue when I took charge of your property. The absolutely necessary expenses of re-timbering, construction of new plant, etc., per-

forming a large amount of exploring work, as well as laying in and paying for a large stock of supplies, have, of course, reduced the profit most materially.

Mr. Attwood then gives extracts from reports of E. S. Blackwell, Clarence King and Andrew Murray, and also from his own report on the mine dated May 14, 1873, all of which agree that the future of the mine must entirely depend on new developments. These reports were all made in 1873, and although we gave them in our last week's issue, we reproduce the extracts from the reports of the three experts, which corroborate the views of the manager of the mine.

June 7.—Report by Mr. E. S. Blackwell, Manager, Ophir Mining and Smelting Company of Utah (Limited): The future of the mine depends entirely upon the virgin ground, and to explore this you must be prepared to wait some time, and spend a large amount of money in developments.

June 11.—Report by Mr. Clarence King, Director of the United States Geological Survey of the 40th parallel:—In conclusion, I can only reiterate that the great Emma bonanza, the object of such wide celebrity, the basis of such extravagant promises, is with insignificant exceptions worked out, and the future of your company is hung on a mere geological chance, which may be eternally against you, and if in your favor may only be secured by the wise expenditure of much time and money.

August 5.—Report by Mr. Andrew Murray, F.L.S., etc.:—In my opinion the famous Emma mine is exhausted, and nothing more is to be expected from it but the leavings of the old workings, the scraping of the walls, the ore which may have been entombed by the cave, the old fillings, and the second-class ore on the dump.

In concluding the report Mr. Attwood has the following to say of future explorations:

I have now found it necessary to abandon work in the bottom of the Attwood winze, partly on account of the great expense incurred in sinking it below its present depth (being 120 feet deep on the angle, and requiring two hand windlasses to hoist the water to level No. 4, owing to a sharp turn or set-off in the winze), and because I consider the engine-shaft the better, as well as the most economical place to continue exploring. I am now moving the pump, and placing it in the bottom of the engine-shaft, and propose to continue the same down to the deep at the present angle, as it will then cut the lines of bedding, and if the deposit is continuous, and shaft continued deep enough, it will again. The exact height of the throw is a most difficult matter to estimate, and I have in plan No. 1 roughly estimated it at 300 feet, but that, of course, is merely a theory based on what data I have been able to collect about the matter. I consider it advisable when the engine-shaft reaches the level of the Attwood winze to connect them together by a drift; also, would strongly advise in sinking or drifting to follow every indication of ore or vein matter that may be discovered, in hopes of its leading to a new deposit of ore. I would also recommend that a cross cut should be run in a

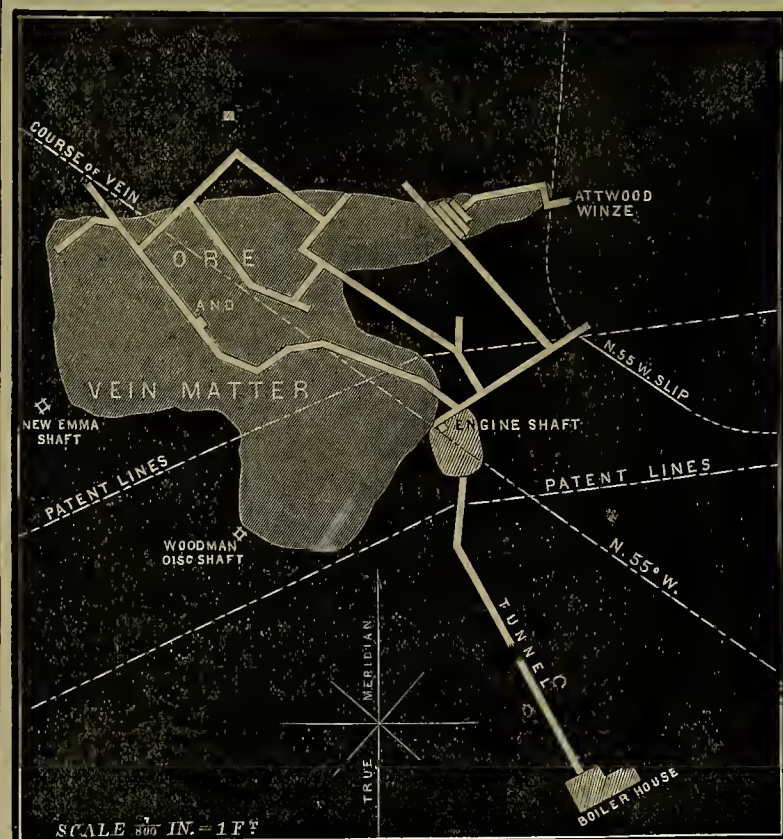

(Continued on Page 364.)

VERTICAL PLAN OF EMMA MINE, SHOWING ORE BODY, ETC.

Lake City, less than \$800, and has been worked in your mine in horizontal and vertical positions, as well as at an angle of 30°. The results of its working have been most satisfactory, and I have now nearly completed a much

serves in sight are very small, and I cannot estimate the amount to be more than 100 tons, which will probably assay 35 per cent. in lead and 100 ozs. of silver per ton. These "reserves" extend from just below level No. 2, to

Ground Plan Showing Position of Ore Deposit with Reference to Porphyritic Dike.

larger one, with a capacity of raising to the surface from your lowest workings over 400 gallons of water per minute, to meet the large amount of water which the mine will undoubtedly have during the coming summer. This new pump will be built for about one-tenth of the cost of a Cornish pump of equal capacity, and enable explorations to be carried on vigorously "to the deep," as well as the extraction of all the mine fillings for concentration, the latter being a most important consideration. The quantity and value of the fillings now in the mine is a most difficult matter to determine with accuracy, but from all measurements and assays that I have been able to make, I should think you have probably about 5,000 tons in

level No. 4, and also to the upper portions of the Attwood winze.

Mr. Attwood gives an account of the concentration works, of which we shall have more to say hereafter. Referring to these works, Mr. Attwood says: Upon taking the management of your property, I soon found it was an absolute financial necessity to adopt some new plan to the one formerly applied in working your ores, as the greater portion of the same consisted of a large mass of very poor material, in which the lead was combined chiefly as carbonate, oxide and sulphate, and at the same time contained such a small percentage of lead and silver that it was much too poor to ship direct, or even select by hand. As soon as the

Change, a Law of Nature.

The law of perpetual variety is well illustrated by Prof. Babbage's calculating machine.

Geology proves that this earth is ever changing. Mountains are being worn away and carried as mud to the plains below. Rivers are daily forming new land at their mouths. Coral insects, in infinite variety, are building up islands, and gradually grooping them into new continents. Submarine forests are raising their little by little, imperceptibly, till central chains of mountains, filled with water, make them habitable and healthful. Marine shells on their annals make everlasting record of this circuit in geologic movement. Volcano and earthquake forces attest internal evolution in the very bowels of the earth.

Not a plant now growing, not an animal nor a race of men now on this planet, is the same as lived here long ages ago. The climates are changed by oscillations of the axis of this revolving globe; and this compels revolutionary changes, or evolutions, by which new animals and plants are evolved by easy gradations from the old; and thus existing races become fitted to the altered conditions of the laws of life.

Astronomy presents like evidence. Our sun and all its revolving worlds, so apparently vast to our conceits, is but an atom in the universe. Tens and hundreds of thousands of similar suns, each with like worlds revolving around it, and each distinct with life vastly differing from ours, in infinite variety, are spread out through measureless space. These know no rest; their very life depends on everlasting movement; not simple, but compound. Each has its rotation on its own axis, and all its worlds have their orbits. Besides, every sun is sweeping through space with wondrous velocity, not in a straight line, but in a vast circuit around some center of powerful attraction and proportion, to us inconceivable.

Everything impresses the astronomer with the probability that suns themselves wear out from unceasing motion, are disintegrated into bright nebulous atoms, and new suns are being re-created. Of course, previously to this, every world becomes disintegrated and falls back upon the sun, from whose substance it originally came. Such a catastrophe will be the end of our world.

Thus, nothing in the universe has immortality of form, while the constituent elements are indestructible and everlasting.

We propose to give a curious and inexplicable illustration of the repugnance of nature to repetition without limitation.

The calculating machine of Prof. Babbage belongs to the British Government. By the laws of its construction, when it is set to produce a series of numbers in succession, it appears that it must continue to produce the same series till it is worn out. For instance, 1, 2, 3, etc., or 2, 4, 6, or 3, 6, 9, etc. But an indefinite repetition of that kind is not permitted by the law of evolution. The machine will go on producing figures in the same order—1, 2, 3, etc., till it reaches 100,000,001. But, without known cause, the machine tires of this repetition, and the next turn of the handle shows on the rim

100,010,002
100,030,003
100,050,004
100,100,005

being a series of triangular numbers, each multiplied by 10,000. Triangular numbers are thus:

	0	0	00	000	0000
0	0	00	000	0000	00000
1	3	6	10	15	

The machine will now continue this series 2,761 times, when it makes another evolution, involving new relationship to numbers still triangular. These changes have been traced through many such evolutions; they are evidently due to some law that is not traceable. It seems to favor Dr. Darwin's law of evolution, not that man was made from monkey, but that by transition, man came, in his turn, by a change in the circuit of creative movement. In our own age we see the process of evolution going on. The grand sequoias of California, the acacias of the Atlantic States, the dogo and the Bushman of Australia, the buffalo and the Indian of North America, the whale of the Arctic seas, etc., are examples. Races of men are undergoing changes equally conspicuous, through intermarriages and removals to new climates, producing constitutional and physiological evolutions.

The inventive Yankee is a new manner of man; and universal education, combined with luxury and the changes of machinery, is working in the mental and physical amelioration and elevation of men, and cannot fail to evolve from existing peoples greatly improved races of men upon the earth.

RAMSHORN GULCH has taken a new lease of life. In 1863-4 it was supposed to have been prospected thoroughly and abandoned as not having anything in it; but recent prospecting has discovered the "pay-streak," and shows it to be very rich; one of the best gulches in the Territory. Water has been brought in; the yield this season promises to be very large. Messrs. Ramsey & Boatman have in a bedrock flume on very rich ground, and are sure of big pay. Messrs. Sedman, Davis & Johnson are putting in a ditch to develop their ground, which prospects very rich, and will in a few days be taking out the dust. Ramshorn will be one of the best camps in the Territory this season. This is a good year for abandoned mining camps.—*Montanian*.

Quicksilver Near Vallejo.

The Vallejo *Chronicle* says: Since the development of the St. John mine, and the demonstration of its richness and extent, the disposition to prospect the hills in this vicinity for further deposits of this valuable metal has received a strong impetus. The hammer and pick of the sanguine prospector have been resonant upon the flanks of Sulphur Spring mountain, and places which centuries had left undisturbed, were turned over and explored by the cinnabar seekers. The results of the numerous prospects are such as will convince anyone that the vicinity of which we speak is the repository of vast and rich bodies of this metal.

Among the new prospects, one by John Wilson is very favorable. This deposit is about two miles northwest of the St. John mine. This place shows a fine cropping of cinnabar of a good quality, with indications of an extensive body of ore. A few miners have been at work for a short time past upon this lead, and it was day before yesterday that they struck the ore.

About half a mile from the St. John furnace, in a northwesterly direction, and not over five hundred yards from some of the drifts of that mine, is one of the most promising developments in the whole range. This is upon the place of Berry Shouse, who is the proprietor of the claim, and is working it. The deposits are found upon a hill embracing about fifty acres, in one corner of his ranch. There is hardly a spot upon this elevation where outcroppings of cinnabar or pieces of the ore cannot be found. A number of men have been employed the past few weeks in prospecting the numerous veins and seams. On one of the principal croppings a shaft has been sunk about 30 feet; showing a wide vein of cinnabar the whole distance. A tunnel is now being run to strike the vein opened by the shaft, and is now in about forty feet. Several tons of ore worth several thousands of dollars, have already been taken out by Mr. Shouse. This tract, which is now proving so rich in cinnabar, has been in Berry's possession since 1858, and is just adjoining his door. Nevertheless, he has little dreamed of its value during the long time; looking upon it rather, by reason of its hilly surface and barren, rocky nature, as a worthless appendage to his farm. Mr. Shouse has already been offered large sums of money for the mine.

J. F. Tobin & D. Williamson commence today to prospect the cinnabar developments upon their ranch. The location is about halfway between the St. John and the Brownlie mines, and there are excellent outcroppings of the metal in sight.

One thing, however, which is almost peculiar to the mines in the Sulphur Spring mountain range, is that they can be opened without any previous outlay of capital. No preliminary shafts and tunnels to determine the existence of the ore are required. The cinnabar is in sight from the surface and can be taken out from the first stroke of the pick until the mine is developed. Consequently, the prospector is not dependent upon capital, and the man who has capital is not required to risk it, as the mine pays for its development from the commencement. We are satisfied that the mines of Pine Flat and the other sections of Napa and Lake, where the excitement about cinnabar is so intense, have none of them the flattering prospects found in the Sulphur range. If, like those localities, moreover, the latter was located upon public lands, open to pre-emption by the prospector, there would be an army of excited prospectors also scattered over its extent.

A NEW MINING INVENTION.—A new style of mining cage yesterday went into use in the Consolidated Virginia mine. The new cage is a three-decker; that is, it hoists three cars at once. Double-deckers have been in use at the leading mines on the Comstock for some years, but this is the first three-decker ever put into any shaft on the lode. Although it holds three cars, it is not as long as those which hold but two; the compartments being only sufficiently high to admit a loaded car, whereas the compartments of the double-deckers are of sufficient height to permit of the tallest men standing in them. Owing to the shortness of the new three-decker, the miners have christened it the "Pup." It is constructed wholly of iron, and is the handiwork of John Holden, head blacksmith of the company, and formerly blacksmith of the Gould & Curry company. The new cage has been placed in the middle compartment of the shaft, and is found to work to perfection. The advantage in the use of the new cage is that it does one-third more work in a given time than the double-deckers. Orders were issued by the foreman the moment the "Pup" was launched in the shaft, that none of the miners were to attempt to either ascend or descend the shaft upon it. As the men would be unable to stand upright in its compartments, it would be unsafe for them to hoard it.—*Enterprise*.

ARIZONA MINES.—A letter from Cedar valley district, Mohave county, Arizona, to the *Citizen*, states that the mines are looking exceedingly well, and new lodes are being discovered almost every week. "Mr. Dave Buell, the great mining man of Nevada, paid us a visit lately, and seemed greatly pleased with our prospects. He says he will put up a mill here very soon. In fact, he located a mill-site on the Big Sandy, and has already built a house on it, and has two or three men at work making other improvements. The boys have great faith in him, and think he really intends doing something.

The Stickeen Mines a Failure.

The Yamhill, Oregon, *Reporter* of the 22d instant publishes the following:

Last Sunday evening a gentleman passed through this place, on the Amity stage, who had just arrived from the Stickeen mines. His name is George Goldy, and he was for some time an employe on the West Side Railroad, between St. Joe and Portland. During the few minutes the stage was in waiting we caught a few items of the gentleman's conversation with acquaintances, regarding that great El Dorado from whence he had just returned. It is very evident he will not go back. He says men are leaving there by the hundred, as fast as they can get away. There were nearly five hundred men at the mines, and a great many between the mines and Wrangle. The weather has been severe, and the men have suffered a great deal on that account, while a number have been drowned on the way up the Stickeen river, by breaking through the ice, and where the river was clear, by the capsizing of canoes. The high-sounding reports in reference to the large yields of gold are greatly exaggerated, and many of them untrue. Produce is very high. Flour is worth \$125 per hundred, and other things in proportion. Transportation is very scarce, and cannot be had at all for less than one dollar per pound. The carrying trade seems to be mostly in the hands of the Indians. We are not very much surprised to hear such a story as this from the "Wonderful Stickeen." It will be a benefit—perhaps the salvation of some of our young friends who are contemplating a trip to Stickeen, to see Mr. Goldy, and receive the information he can impart, and act according to his advice. We are aware that there have been high-colored descriptions of the new "golden land," and its prospects pictured out in the most flattering style; that these glowing accounts have been published far and wide by certain parties, and the utmost done to create a sensation; and all this has had the effect to load certain steamships with the rush of men which those publications have created. Those who keep the flattery stirring are interested parties, and even after it is known from other sources that the mines are not all they are reported to be, these same parties continue to throw out the alluring bait, to lads who may be led by it to go to Stickeen.

The Prospector's Friend.

The San Juan *Prospector* says: The busy notes of preparation have been heard among the miners during the whole of the past week. Many have already started, and many others are busy making the necessary preparations. Everything needed for a trip to the mines, including grub, mining tools, powder, fuse, etc., are being collected together, and the indispensable burro, the miner's pack animal, is of course in demand. This faithful animal is as indispensable to the miner as his butcher-knife and pistol. Like Justice, he is sometimes slow, but is sure. He is of light weight, too, so that in case a difficult mountain road is reached a stout man can take him on his shoulders and safely transport him over the obstacle intervening. He is a very domestic animal, and is always disposed to be on very intimate terms with his master. In fact he carries his friendliness so far that, as we are informed by old prospectors, he sometimes attempts to locate in the same bed with his owner. The expense of keeping him, too, is not great, as he is not an epicure, and will eat anything from a piece of bacon rind, or a pound or two of chili Colorado, to a keg of powder. He is a good companion in the mountains, with the exception that one has to be careful to securely fasten the cabin door, when leaving for work, or the probabilities are that when he returns he will find that a summer grab-stake has vanished.

EBERHARDT & AUORA.—Miners from the hill represent the mines of this company to be looking splendidly, and a noticeable improvement is manifest as depth is attained. The famous Peerless chamber, since its discovery a year ago, has yielded many hundred tons of magnificent pay ore, and the supply seems even now to be inexhaustible. In the Ward Beecher (the English Ward Beecher) work is being vigorously prosecuted, resulting in finding large bodies of pay ore. The mines are producing sufficient quantities of rock to keep the mill at Eberhardt in motion constantly, and leave a reserve for accidents, etc. Mill superintendent Robinson comes up once in a while with silver bricks, the result of the workings of the mill. Being the only live institution in the county just now, we have to look to its disbursements for the actual support of our county. The managers deserve great credit for the energy displayed under a variety of adverse circumstances, in keeping the works running during the past terrible winter.—*White Pine News*.

HEAT AND COLD.—As an instance of the effect of heat and cold in expanding and contracting the iron of the dome of the National Capitol, it is stated that the colossal statue surmounting it inclines $4\frac{1}{2}$ inches to the west in the forenoon, and the same distance to the east in the afternoon. This fact has been ascertained by fixing a plumb line to the statue and dropping it to the rotunda below. As the morning sun upon the east side of the dome heated the iron and caused an expansion on the side of the statue, it was thrown westward $4\frac{1}{2}$ inches. In the afternoon, when the sun upon the west side heated and expanded that side of the dome, the statue inclined to the east a similar distance.

Montana Placer Mines.

A correspondent of the Helena (M. T.) *Independent* writes as follows from Blackfoot: The prospect for a plentiful supply of water in this camp for the entire mining season looks very discouraging indeed. The snow has all disappeared along the foothills, and no perceptible rise in water is observable—a very unusual thing for this country. Even now the high mountains at the head of Three-Mile creek and Ophir gulch are nearly bare. However, at the present time the Ohio ditch, taken out of Three-Mile creek, and owned by Pounda and Green, of Carpenter's bar, is carrying its full capacity of water. The Tiger ditch, taken out of Ophir, and owned by Bratton & Pemberton, is also carrying its full capacity. This ditch is mainly supplied by spring, and it is believed will furnish a good supply of water the entire season. The boys are determined to economize and make the best of it; and while the water lasts will make times lively. On Ophir bar mining commenced some time since, and some satisfactory clean-ups have been made. Several companies are still ground-slicing, not having made a clean-up yet.

Illinois Gulch is now owned by two companies who are working it by means of bed-rock flumes. Work commenced a month ago, and some good clean-ups have been made.

In Balsara Gulch, west of Blackfoot, mining commenced a month ago. Last year some good paying ground was developed in different parts of this gulch, and if the supply of water was sufficient, would give employment to a large number of men. On Ohio Bar, also, some good paying ground has been found and developed, a scarcity of water being the only drawback.

During the last winter, Bratton & Pemberton have had men engaged in constructing a ditch from Ophir gulch to Nelson hill, and by the 1st of June will have it completed. The line of this ditch is about seventy-five feet higher than any previously constructed, and will cover a large area of valuable mining ground. It will in every way double the importance of this place as a mining camp.

At Carpenter's Bar mining has commenced generally. No clean-ups have been made yet.

At Snow Shoe the miners commenced work a month since. Considerable was done during the past winter with good result. Water will be plenty the entire mining season.

The miners in Gold Cañon took out immense dumps during the past winter, and as yet have not finished washing up, but so far good clean-ups have been made.

SAPPHIRES IN COLORADO.—The Denver, Col., *News*, says: "A miner, who has been engaged, some months past, working in the bars along the Platte for five or six miles above Denver, had the good fortune to find several sapphires, which he saved, without knowing anything about their value. One day last week a stranger, who was prospecting down the river [was shown the stones, when he bought the largest for two dollars. He brought it to town, and upon a test it was pronounced a sapphire, and a very fine one. It was placed in the hands of I. Haber, lapidary, to be cut. The rough stone weighed nineteen and a half carats, and was valued at \$500. The miner was also in town yesterday, and became very much astonished upon learning the value of the pebble he had parted with for a two-dollar greasack. He left two more with Mr. Haber, and proposes to enjoy himself, some of the profits of their polishing. The gentleman who bought the first mentioned stone is experienced in such things, though a comparative stranger in this region. In the past week he has himself found, within two miles of Denver, an emerald, which he believes more valuable than the sapphire, and a very fine water agate, which will produce a beautiful gem of strawberry color. He has sent the emerald East. Three diamonds have been exhibited in Denver, in the past week, that the owner said were found in Colorado, and east of the range. We cannot vouch for the truth of this report, but there is no question as to the fact that the others were all found within less than six miles of the Denver post-office."

GOOD YIELD.—Mr. E. Fender informs us that Frederick's 5-stamp quartz mill, over on the Haasayampa, is a success. It grinds on an average, about six tons of hard gold rock every day. The last ran was upon $3\frac{1}{2}$ tons of rock from the Crossins mine, which yielded as well as could be expected; the run having been made on second-class ore. The clean-up had not been completed when Mr. Fender left, but from the battery and plates 144 ounces of amalgam had been taken, with the arrastras yet to "hear from." One after another these evidences of the wealth of the surrounding country, and the ease with which it can be extracted, are thrust upon us, and we look back with regret upon the concern which, through ill-management, not only bankrupt their owners but detracted from the merit of Arizona, thereby robbing us of the assistance we so much needed and now need—the wherewith to develop.—*Arizona Miner*.

ARIZONA MILL.—The improvements in the Arizona mill are rapidly nearing completion. A few weeks more and the machinery will all be in place and the mill ready to commence crushing ore from the Arizona mine.—*Silver State*.

It is said there is a marked falling off in the yield of the South African diamond mines, and diggers who remain are much discouraged.

GRAND INDUSTRIAL EXHIBITION,

To be held under the auspices of the

MECHANICS' INSTITUTE

OF SAN FRANCISCO, CALIFORNIA,

Opening on August 18th, 1874.

The Board of Managers herewith announce that a grand Industrial Fair will be held in the city of San Francisco for 30 days, opening on August 18, 1874.

In view of the increasing commercial and manufacturing importance of San Francisco, its contiguity to and close connection with the various countries bordering on the Pacific, the managers have constructed a Pavilion having a floor area of 150,000 feet, and have invited to it all who are disposed to come and exhibit. All exhibitors will be placed on the same footing. Motive power will be furnished free.

The building will be open day and evening, and every facility will be extended to exhibitors and visitors.

Application for space must be made without delay to the Secretary of the Board of Managers, 27 Post street, San Francisco, and all inquiries will be answered and information extended promptly.

No space can be secured unless applied for before the 20th of July next.

A. S. HALLIDIE, Pres.

ARE YOU GOING TO PAINT?

THEN USE THE BEST.

THE AVERILL CHEMICAL PAINT

WILL LAST THREE TIMES AS LONG as the best lead and oil, without OALKING; is of any desired color. It is prepared for sufficient application, requiring no Oil, Thinner or Drier, and does not spoil by standing any length of time. It is equally as good for inside as outside work; over old work as well as new; in fact, where any paint can be used the AVERILL CHEMICAL PAINT will be found superior to any other. Any one can apply it who can use a brush, which truly makes it the FARMER'S FRIEND.

IT IS JUST THE PAINT FOR THE AGE.

IT IS SOLD BY THE GALLON ONLY.

One gallon covers 20 square yards 2 coats.

For further information send for sample card and price list.

(Continued from Page 361).

northerly direction through the slide, where the last ore was discovered in the Attwood winze. The future chances of finding a new deposit of ore rest most undoubtedly on a geological problem; but as long as you have any funds in hand I do not think your property should be abandoned, but exploration carried on as I have just advised—and that, too, in a careful and economical manner. Your mine superintendent, Mr. Hannibal Williams, has been most unceasing in his efforts during my term of management, and deserves great praise at your hands, for the able manner in which he has carried out my instructions. The same can also be most justly said about our mining captain, Mr. John Raby. Mr. Charles Smith, the cashier and clerk, has been of great service to the company, and I have found him to be a most competent clerk, as well as a trustworthy cashier and servant.

We give the statement of accounts, which show some interesting figures:

ORE ACCOUNT.	
Dr.—To expenses at Salt Lake.....	£65,662 16 8
Suspense account.....	1,711 19 3
Balance to revenue account.....	16,990 10 6
Total.....	£74,365 5 5
Cr.—By 6,597 tons of ore at Salt Lake City and St. Louis, less 540 tons raised ore on hand, Dec. 31, 1872.....	£67,427 15 5
214 tons raised ore on hand, estimated at.....	6,337 10 0
Total.....	£74,365 5 5

In the foregoing the expenses at Salt Lake are included—24,632, as salaries and wages; 11,105, for hauling ore from mine to rail; 3,232, for assaying and sampling; and 4,632, for timber and expenses of sawing and hauling. The suspense account includes 1,133, for law charges in the Illinois suit.

Total.....	£1,050,141 0 2

The debtor account does not include £1,770 16s 8d director's fees, due at December 31, and yet unpaid.

Academy of Sciences.

The regular semi-monthly meeting of the California Academy of Sciences was held on Monday evening last, Vice-President Hewston in the chair. The following new members were elected: William Ditch, G. Parker Cummings and John H. Saunders. The donations to the museum were not extensive. A collection of ancient pottery, the specimens artistically wrought and perfectly preserved, were exhibited on the table. General Hewston stated that the collection had lately been consigned to him for the Academy, but no communication in reference thereto had yet reached him. It was believed that the specimens came from Peru, and had been sent by Benjamin Smith or James Freeborn, two members of the Academy who are now traveling in South America. W. H. Turner presented the pupa of a large species of beetle, native of Mexico. A fine specimen of Suisun marble, with a polished surface, was presented by a member.

D. W. C. Gaskell, of Forbestown, left on exhibition remarkably well-preserved teeth and a tusk of the mastodon and of the fossil elephant, found at New York Flat, Yuba county, deposited in auriferous gravel, on the bedrock, 15 feet below the surface.

George C. Hickox presented to the library a well preserved antique volume, entitled, "A Catalogue and Description of the Natural and Artificial Rarities Belonging to the Royal Society, and Preserved at Gresham College," by Nehemiah Grew, M.D., Fellow of the Royal Society and of the College of Physicians, London. Printed by W. Rawlins for the author, 1681. The usual variety of fresh scientific publications were laid on the table.

T. J. Lowry, of the U. S. Coast Survey, read a paper descriptive of an improved method of observing the sun at sea. The improvement consists of a method by which both the upper and lower limbs of the sun can be observed at the same time by duplicating the image of the object by means of the instrument. We will describe the operation in detail in a future issue.

James Lick's Generosity.

San Francisco is honored by having as one of its residents a man, who, having accumulated large wealth, possesses the moral courage which allows him to distribute that wealth among public institutions, before his death. Such a man is James Lick, of whose liberality we have spoken frequently, and who has just given his immense fortune to the services of his fellow men. A deed was recorded on Wednesday in the office of the County Recorder, in which Mr. Lick deeds all of his property to certain gentlemen in trust, for the purposes hereafter mentioned. The Trustees are Thos. H. Selby, D. O. Mills, H. M. Newhall, William Alvord, George H. Howard, James Otis and John O. Earl.

These trustees are empowered to sell certain property when and on what terms they may think best, so as to convert it into money for the purposes detailed below. The first item mentioned the proposed observatory, of which we have frequently spoken. Out of the proceeds of the sale and disposition of the property hereby conveyed and transferred, and intended to be, to pay the sum of \$700,000, for the purpose of constructing on the lands heretofore deeded to James Lick, by H. M. Yerriington and others, the said lands being situated on the borders of Lake Tahoe, State of California, a powerful telescope, superior to and more powerful than any telescope yet made, with all the machinery appertaining thereto and appropriately connected therewith, or that is necessary and convenient to the most powerful telescope now in use, or suited to one more powerful than any yet constructed; and if, after the construction of said telescope, there shall remain of the said \$700,000 any surplus, then the said parties of the second part shall invest the same in United States, California, or City and County of San Francisco bonds bearing interest, and donate the income thereof to the maintenance of said telescope and the observatory connected therewith and make the same useful in promoting sciences.

Any vacancy occurring in the Trustees, by death or otherwise, shall be filled by a majority of the remaining Trustees, selecting some well known citizen or citizens, residents of the State of California, so that science may lose nothing by their incapacity, inattention or otherwise.

Said parties of the second part to provide said sum of \$700,000, and apply it to the erection of said telescope and observatory and the adornment and improvement of the grounds selected for a site, as rapidly as judicious construction will permit. Said parties of the second part being prohibited from mortgaging such site, or the appurtenances to be connected therewith, and from contracting any debt in connection therewith.

The deed then gives \$25,000 in gold coin to the Protestant Orphan Asylum in San Francisco. The city of San José, Santa Clara county, Cal., is to have \$25,000 to build an orphan asylum. The Ladies' Protection and Relief Society, \$25,000. To the Mechanics' Institute Library, \$10,000, to be applied to the purchase of scientific and mechanical works. To the Society for the Prevention of Cruelty to Animals, \$10,000, accompanied with a hope that the Trustees of said Society may organize such a system as will result in establishing a similar society in every important town in California; to the end that the rising generation may not witness or be impressed with the everyday occurrences of cruelty and brutality, as hee often taken place in this State.

He orders \$5,000 to be devoted to the erection of a monument to the memory of his mother, Sarah Lick, who died at Fredericksburg, Pa., in 1812; and also \$5,000 to the memory of his father, James Lick, who died at the same place in 1831. The sum of \$5,000 is devoted to the erection of a marble monument to the memory of his grandfather, William Lick, who died near Norristown, Pa., at the age of one hundred and four years, to commemorate the services rendered by him in the American struggle for independence, and the hardships he suffered at Valley Forge and other places during said struggle; all of said monuments to be erected at Fredericksburg aforesaid. He also gives \$5,000 for the erection of a monument to his sister Catherine.

The trustees are authorized to expend \$100,000 to found an institute to be called the "Old Ladies' Home," to be located in San Francisco; as a retreat for women who are unable to support themselves and who have no resources of their own; the right of admission to be prescribed by A. B. Forbes, J. R. Roberts, Ira P. Rankin, Robert McElroy, and H. M. Newhall.

They are also to expend \$150,000, under the direction of H. M. Newhall, Ira P. Rankin, J. D. B. Stillman, John O. Earl and W. C. Ralston, and the survivors of them and others, in the erection and maintaining in San Francisco of free baths, the sites thereof to be acquired and held by the persons last named, in trust, to for ever maintain such baths for the free use of the public.

The sum of \$150,000 is devoted to the erection of a bronze monument to the memory of Francis Scott Key, author of the song "Star Spangled Banner."

Mr. Lick's love for California is shown in the following, as well as the other gifts: To erect, under the supervision of W. C. Ralston, John O. Earl, Dr. J. D. B. Stillman, H. M. Newhall and Ira P. Rankin, and their survivors, in the State Capitol grounds, at such places as shall

be selected by the Governor, Attorney-General and Chief Justice of the Supreme Court, a group of statuary, well worth \$250,000, which shall represent by proper figures and designs the history of California, from the early settlement of the same by the United States, and the style of architecture illustrating the same from the acquisition of California by the United States to the time when agriculture became the leading interest of the State; also, illustrative of the progress in mining, manufacturing, mercantile pursuits; the gradual development of agriculture, and also its history from the last mentioned period to January 1, 1874; illustrating the progress of the State in education; the parties to advertise for one year a reward of \$10,000 for the best design of the same, and \$5,000 for the second best design, the rewards to be paid out of the \$250,000.

The sum of \$300,000 is to be applied to the endowment of "The California School for Mechanic Arts," the object of which shall be to educate males and females in the practical arts of life—such as works in wood, iron, stone or any of the metals, and in whatever industry intelligent mechanical skill now is or can hereafter be applied, said institution to be open to all youths born in California; the institution to be under the direction of J. D. B. Stillman, Horace Davis, A. S. Hallidie, Joseph Eldridge, John O. Earl, W. C. Ralston and Hon. Lorenzo Sawyer, who are to acquire the site, form a corporation and erect the buildings, and have power to fill vacancies.

The Trustees are authorized after discharging the above named trusts to deed the remainder of his property to the California Academy of Sciences and the Society of California Pioneers, to be expended under the direction of a majority of the parties of the second part, in the erection of the buildings mentioned in the deeds to said societies respectively, dated October 3, 1873, and in the purchase, after the erection of such buildings, of a suitable library, national specimens, chemical and philosophical apparatus, and rare and curious things useful in the advancement of science.

Mr. Lick then gives the sum of \$26,000 to various relations mentioned; and reserves for his own use during his lifetime the management of said homestead property, the furniture, books, tools and implements thereof, and the rents, issues and profits thereof. As some of the real estate is encumbered, the parties of the second part are charged with paying the debts due.

The trustees are to make over to the Academy of Sciences and Society of Pioneers, after Mr. Lick's death, his homestead in San José and all personal property in his business office in this city. In consideration the trustees are directed to pay to Mr. Lick from week to week, such sums as he desires, not to exceed \$25,000 per year, until his death.

It will be seen that Mr. Lick has given away all his immense property; and most of the purposes to which it is to be applied, are most deserving ones. It is very seldom a man is to be found who will give up his property in this manner. He gives it out of his own control entirely. Exclusive of the gifts to the Academy of Sciences and Pioneer Society, these magnificent gifts amount to \$1,780,000. The property already given to the Academy amounts to some \$250,000, and the building which he has planned for it, and now desired built, will cost \$250,000 more. Whatever remains, will go towards an endowment.

This generosity is unparalleled; and few will cavil at the manner of distribution of the money. The purposes to which it is applied will redound to the honor of this State as well as to that of Mr. Lick, and his name will be handed down to future generations as a benefactor of mankind. It will be a credit to this State abroad and at home, that there is within its boundaries a man who is willing to give such immense wealth for the purposes named.

MECHANICS' INSTITUTE.—The annual election or Trustees of the Institute was held on the 1st inst., and resulted as follows: Total number of votes cast, 151, of which A. S. Hallidie, manufacturer of wire rope, received 141; Asa R. Welle, millman, 141; R. B. Woodward, proprietor of Woodward's Gardens, 143; W. P. Stont, attorney-at-law, 151; Henry L. Davis, banker, 141; George Spaulding, painter, 143; James Spiers, machinist, 142.

AMERICAN MUSEUM OF NATURAL HISTORY.—The corner stone of the new American Museum of Natural History was formerly laid in Manhattan Square, New York, on the 2d inst. The building was begun last fall and will be completed eighteen months hence, and will be twenty-five feet longer than the Capitol at Washington. The museum will cost \$6,000,000.

The St. John's mine, of Solano county, shipped sixty-three flasks of quicksilver on Monday, being the last lot of 149 flasks for the month of May.

DONNER LAKE is said to be higher now than it has ever been known to be before, and it is still rapidly rising.

ANOTHER vein of coal has been struck by the Bellingham Bay Coal Company, at a depth of seventy-seven feet.

A NEW city is springing up on the Jefferson river, Montana, consequent on the recent mining developments there.

Mr. Knighton, Deer Valley, El Dorado, recently picked up a nugget of gold weighing twelve ounces.

The forty-niners of North San Juan and adjacent towns contemplate a reunion on the fourth of July.

A LINE of stages has been put on the route between Battle Mountain and the Jersey mining district.

THE Idaho mine, Grass Valley, turns out gold bricks worth from \$20,000 to \$25,000 weekly.

THE shaft on the New York Consolidated mine, Washoe, is now drained within 200 feet of the bottom.

THE Idaho (Grass Valley) mine cleaned up \$21,000 one day last week, after a five days' run.

THERE will be more prospecting in quartz mines about Columbia this season than ever before.

THE Consolidated Virginia produced \$413,400 in bullion during the month of May.

THE Grass Valley Eureka mine cleaned up 525 ounces of gold amalgam last week.

THE Missouri cinabar mine, Leake county, produces 30 flasks of quicksilver a month.

SEVERAL new quartz mills are in course of erection in Calaveras county.

THERE are 9,000 Chinamen to 1,000 whites in and around Oroville.

THE Plumas Ditch Company, on Badger Hill, are running night and day.

PATENTS & INVENTIONS

A Weekly List of U. S. Patents Issued to Pacific Coast Inventors.

[FROM OFFICIAL REPORTS FOR THE MINING AND SCIENTIFIC PRESS, DEWEY & CO., PUBLISHERS AND U. S. AND FOREIGN PATENT AGENTS.]

By Special Dispatch, Dated Washington, D. C., June 2, 1874.

FOR WEEK ENDING May 19, 1874.

TICKET CLASP.—Hiram N. Rucker, Plainsburg, Cal.

MOLN-BORN FOR PLOWS.—Don Carlos Matteson and Truman P. Williamson, Stockton, Cal.

RE-ISSUE.

VALVE FOR PUMPS.—Wm. D. Hooker, S. F., Cal.

"The patents are not ready for delivery by the Patent Office until some 14 days after the date of issue. NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & CO., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest time possible.

The Mining & Scientific Press.

Started in 1860, is one of the oldest weekly journals now published in San Francisco. It has been conducted by its present proprietors for ten years, during which period it has been repeatedly enlarged and constantly improved. The active and steadfast efforts of its publishers have gained for its conduct an amount of practical experience greater than any other publishers have accumulated on this coast, of a weekly journal.

The sum paid by us for the best editorial talent obtainable for our special class journal; for engravings, for interesting news and correspondence, and for printing a large-sized, handsome sheet, is unequalled by that of any other American weekly west of the Mississippi.

As a PRACTICAL MINING JOURNAL it has no rival on this Continent.

It is the only MECHANICAL, and the only SCIENTIFIC journal of the Pacific States, and the only Scientific journal of the United States should take it.

Every Miner, Assayer, Millman, and Metallurgist in the United States should take it. Every Pacific Coast Mechanic, Engineer, Inventor, Manufacturer, Professional Man, and Progressive and Industrial Student should patronize its columns of fresh and valuable information.

Every Mining Engineer, Superintendent, Metallurgist, Mine Owner and Mine Worker in the world should profit by its illustrations and descriptions of New Machinery, Processes, Discoveries and Record of Mining Events.

Every intelligent thinker in the land, in high or humble situation, who would avoid literary trash for genuine information, should SUBSCRIBE AT ONCE.

DEWEY & CO.,

No. 338 Montgomery street, S. F.

Our Agents.

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.

L. P. McCARTY—General Agent.
A. C. KNOX, City Soliciting and Collecting Agent.
W. H. RATTENBERRY—California.
CHAS. W. OTIS—Solano County.
C. M. DALY—Colusa County.
CHAS. T. BELL—Alameda, Santa Clara and Santa Cruz Counties.
J. D. CAREY—Sonoma County.
J. W. ANDERSON—Orange and Santa Ana, In Los Angeles County, Cal.
HOON ALSTON—San Luis Obispo, San Bernardino and San Diego Counties.

New Inventions!

Of real merit, if brought plainly before the public when fresh, are most likely to become profitable to the patentee. For this reason, patentees (of worthy devices) should have the best of Engravings Made, and published in the Press. Superior Engravings Made, at reasonable rates, by artists in this office. hp-tf

EAGLE IMPROVED CHLORINIZING AND DESULPHURIZING FURNACE.

(Patented July, 1873.)

The Cheapest and Most effective Furnace now in use Parties desirous of building above furnace, or for any information on same, address,

I. T. MILLIKEN,

ja31-2tam No. 302 Montgomery st., room No. 14, S. F.

N. Seibert's Eureka Lubricators.

THE HIGHEST PREMIUM

Awarded by the Mechanics' Institute Fair, San Francisco, and State Fair, Sacramento, 1871.

These Lubricators are acknowledged by all engineers to be superior to any they have ever used; feed constantly by pressure of condensed water, supplied by pipe A, regulated under the oil by valve J, and forced out through check valve and pipe B into the steam pipe C; it then becomes greasy steam, passes to all the valves and cylinder at every stroke of the engine; glass tube I indicates amount used, per hour. Packing on rods and stems lasts longer, and the rings on the piston will not corrode. One pint of oil will last from three to six days, according to speed and size of engine; I, sliding gauge; K, valve to shut off when engine stops; H, F, valves to shut off in case of frost; steam does not enter the cup; it is always cool; warranted to give satisfaction. Patented February 14, 1871. Made by California Brass Works, 125 First Street, S. F. 24v23tf

TO HYDRAULIC MINERS.

I warn Hydraulic Miners not to be misled by the advertisement of Mr. F. H. Fisher. Said Fisher has been beaten in every suit to which he has been a party (respecting Patent Rights on Hydraulic Machines), whether as plaintiff or defendant.

His patrons have already paid over Five Thousand Dollars for license to use machines purchased of the self styled

"Only Reliable Party in the Business Who Protects His Customers."

Fisher's Machine is worthless unless the discharge pipe is furnished with appliances, the patent for which is owned by Messrs. CRAIG, and which Fisher is enjoined from making.

The Machine itself is also an infringement on another patent owned by the same parties.

All persons infringing on either of these patents

WILL BE PROMPTLY PROSECUTED.

I am sole LICENSEE to sell Machines manufactured under Craig's, Rice's, Macey's and Hoskin's patents.

I Guarantee Full Indemnity to all my Customers.

Machines of all size always on hand.

If you want a Machine that will give satisfaction, and do not want to pay for it twice over, buy an Improved LITTLE GIANT.

For further particulars apply to

R. HOSKIN, Dutch Flat,
Or R. R. & J. CRAIG,

Examination solicited.

TREADWELL & CO.'S UPRIGHT SAFETY ENGINES.

2 to 10 Horse Power.

MADE BY THE N. Y. SAFETY STEAM POWER CO. Has tubular boiler, and therefore is secure against the dangers common to shell boilers. Power is taken from near the base, which avoids vibration or top-heaviness. Occupies but two feet square of floor space and is so simple a boy can run it. All its parts are easily accessible—a great advantage. Is complete in itself as a Portable Engine and Boiler, or the engine can be detached from the boiler and run independently, if required. Its main points are simplicity, safety, and economy. For printing offices, laundries, tanneries, ranches, small repair and machine shops, or for hoisting wherever a small and safe power is required, they are peculiarly adapted.

Refer to the following parties who have them in use
E. DETTRICH & CO., Bag Factory, San Francisco;
PACIFIC CHEMICAL WORKS, San Francisco;
ST. IGNATIUS COLLEGE, San Francisco;

IMPORTERS OF AND DEALERS IN ASSAYERS' MATERIALS Chemical Apparatus and Chemicals, Druggists' Glassware and Sundries, PHOTOGRAPHIC GOODS, ETC., 512 and 514 Washington street, SAN FRANCISCO

We would call the special attention of Assayers Chemists, Mining Companies, Milling Companies, Prospectors, etc., to our large and well adapted stock of

ASSAYERS' MATERIALS

—AND—

Chemical Apparatus,

Having been engaged in furnishing these supplies since the first discovery of mines on the Pacific Coast.

Our Gold and Silver Tables, showing the value per ounce Troy at different degrees of fineness, and valuable tables for computation of assays in Grains Grammes, will be sent free upon application.

7v25-tf JOHN TAYLOR & CO.

Varney's Patent Amalgamator.

These Machines Stand Unrivalled.

For rapidly pulverizing and amalgamating ores, they have no equal. No effort has been, or will be spared to have them constructed in the most perfect manner and of the great number now in operation, not one has ever required repairs. The constant and increasing demand for them is sufficient evidence of their merits. They are constructed so as to apply steam directly into the pulp, or with steam bottoms, as desired.

This Amalgamator Operates as Follows.

The pan being filled, the motion of the miller forces the pulp to the center, where it is drawn down through the aperture and between the grinding surfaces. Thence it is thrown to the periphery into the quicksilver. The curved plates again draw it to the center, where it passes down, and to the circumference as before. Thus it is constantly passing a regular flow between the grinding surfaces and into the quicksilver, until the ore is reduced to an impalpable powder, and the metal amalgamated.

Settlers made on the same principle excel all others. They bring the pulp so constantly and perfectly in contact with quicksilver, that the particles are rapidly and completely absorbed.

Mill-men are invited to examine these pans and settlers for themselves, at the office, 229 Fremont Street, San Francisco

E. N. RIOTTE, JAS. L. BETEA, S. O. BROWN.

AUBURN MILL COMPANY, Reno, Nevada.

Purchase Silver Ores in quantities of ten tons and upwards, delivered on board the cars at San Francisco or Oakland at the annexed 1st Rates, WITH NO CHARGE FOR SAMPLING OR REDUCTION. On lots of less than 10 tons, freight to Reno will be deducted.

Special Rates for Gold Ores.

On Gold contained in Silver Ores to the amount of \$30 and upwards, 50 per cent. will be paid. When less than \$30, and above \$10, the amount will be added to the Silver value. Snacks promptly returned free of charge. Ores sampled by Battery or Sampling Mill as shipped may elect, and returns made promptly by cheque on San Francisco.

Ours is the OLDEST, LARGEST and MOST EXTENSIVELY KNOWN establishment of this kind on the Coast.

We also crush and pulverize all kinds of Marble, Fire-Clay, Bricks, Coke, Cement, etc., upon the shortest notice, for which we have special mills.

Reliable information furnished to miners and ore dealers concerning shipments, freights, prices, etc. Prompt execution of all orders. Faithful attention to business entrusted to us.

Abundant storage room without extra charge.

ja31-tf "JIM" WHITLATCH, Sup't.

Morris' Settler and Amalgamator.

PATENTED MARCH 25, 1873.

An important improvement in milling. Cheap, light, efficient and durable. Gains Quicksilver on working tailings. Is discharged from the surface in the center instead of the side, by means of a Syphon which extends to near the center of the Settler. Heaviest casting weighs only 135 pounds. The sides and bottom of the Settler are made of wood, as also Mullers, placed vertically—the friction of which brightens the quicksilver. One of these machines is in daily operation at No. 616 Merchant street, (basement), San Francisco. Parties desiring information as to rights of use, purchase, etc., can address, FREDERICK MORRIS, 616 Merchant St., S. F. 8v28-3m

REMOVED TO 180 FULTON STREET 10v28-3m

DEWEY & CO.,
American & Foreign Patent Agents,
 OFFICE, 338 MONTGOMERY STREET, S. F.

The best, speediest, and surest method for you to obtain patents, file caveats, or transact any other important business with the Patent Office at Washington, or with foreign countries, is through the agency of DEWEY & CO., PUBLISHERS OF THE MINING AND SCIENTIFIC PRESS, SAN FRANCISCO, an able, responsible, and long-established firm, and the principal agents on this side of the continent. They refer to the thousands of inventors who have patronized them, and to all prominent business men of the Pacific Coast, who are more or less familiar with their reputation as straightforward journalists and patent solicitors and counsellors. We not only more readily apprehend the points and secure much more fully and quickly the patents for our home inventors, but with the influence of our carefully read and extensively circulated journals, we are enabled to illustrate the intrinsic merits of good patents, and secure a due reward to the inventor, besides serving the public who are more ready to give a fair trial, and adopt a good thing, upon the recommendation of honest and intelligent publishers.

To Obtain a Patent,

A well-constructed model is generally first needed, if the invention can well be thus illustrated. It must not exceed 12 inches in length or height. When practicable, a smaller model is even more desirable. Paint or engrave the name of the article, and the name of the inventor, and his address upon it.

Send the model (by express or other reliable conveyance), plainly addressed, to "DEWEY & CO., MINING AND SCIENTIFIC PRESS OFFICE, SAN FRANCISCO." At the same time, send a full description, embodying all the ideas and claims of the inventor respecting the improvement describing the various parts and their operations.

Also send \$15 currency, amount of first fee of the Government. The case will be placed on our regular file, the drawings executed, and the documents made up, and soon sent to the inventor for signing.

As soon as signed and returned to us with the fees then due us, it will be sent straightway to the Patent Office at Washington.

When the invention consists of a new article of manufacture, a medicine, or a new composition, examples of the separated ingredients, sufficient to make the experiment (unless they are of a common and well-known character), and also of the manufactured article itself, must be furnished, with full description of the entire preparation.

For Processes, frequently no model or drawings are necessary. In such case, the applicant has only to send us an exact description, and what is desirable to claim.

For designs no models are necessary. Duplicate drawings are required, and the specifications and other papers should be made up with care and accuracy. In some instances for design patents two photographs, with the negative, answer well instead of drawings.

For further information, send a stamp for our illustrated circular, containing a digest of PATENT LAWS, 112 illustrated mechanical movements, and HINTS AND INSTRUCTIONS regarding the RIGHTS AND PRIVILEGES of inventors and patentees, which will be furnished post paid. Also a copy of NEW PATENT LAW of 1870.

v22-3m16p

THE SECOND ANNUAL EXHIBITION

—OF THE—

Inter-State Industrial Exposition

OF CHICAGO.

Will Open September 9th, and Close October 10th, 1874.

SPECIAL FEATURES for this year are MACHINERY IN OPERATION, and Processes of MANUFACTURE. The largest and best Exhibition Building on the Continent. The most liberal arrangements for Exhibitors in every class, and the best and cheapest method of advertising for all Artisans, Manufacturers and Inventors. Space, Steam Power, and Shafting free. Applications should be made, as early as possible, to

JOHN P. REYNOLDS, Sec'y.

Chicago, May 26th, 1874.

jm6-1t

PURCHASERS please say advertised in Scientific Press.

THE ONE-PLUNGER JIG,

Delivered on R. R. Car at Denver, Col., or St. Louis, Mo..

CONTAINING SIX REIVES, END TO END,

Separates in one and the same operation—1. galena and sulphide of silver; 2. pyrites or blende; 3. tailings, containing no valuable parts; or, 1. gold; 2. pyrites; 3. tailings (quartz, etc.), containing no valuable parts; or, 1. copper; 2. tailings, containing no valuable parts. The One-Plunger Jig can be combined with existing stamp-mills with highly important advantages, as after amalgamation it will recover completely all fine metals and all base ores and all mercury out of tailings. It concentrates all fine metal ores to such cleanliness that low grade ores can be shipped, after concentration, as first-class ores. Its feed and discharge are automatic. Its construction offers better guarantee against loss and repairs than any other apparatus in use. For particulars, apply to the inventor,
F. CAZIN,
 Mining and Civil Engineer, Denver City, Col.
 L. Box 2225. 13v28-1y

McAFEE, SPIERS & CO.,

BOILER MAKERS

AND GENERAL MACHINISTS,

Howard st., between Fremont and Beale, San Francisco

KABATH & LADD,

109 California Street, SAN FRANCISCO.

HAVE JUST RECEIVED IN PRIME ORDER, PER
 "CLEOPATRA" AND "SOLOMON,"

A FRESH SUPPLY OF

EASTERN IRON KEG POWDER,

Manufactured by the World-Wide Known

LAFLIN & RAND

POWDER COMPANY.

PATENT SAFETY FUSE,

Electrical Blasting Apparatus, Electrical Fuse, Rubber Tubing,

LEADING AND CONNECTING WIRE CAPS, ETC.,

AND EVERYTHING IN THE LINE OF

MINE & MILL SUPPLIES.

Send for Further Information.

W. T. GARRATT,
CITY
Brass and Bell Founder,
 Corner Natoma and Fremont Streets,
 MANUFACTURERS OF
 Brass, Zinc and Anti-Friction or Babbet Metal CASTINGS.

Church and Steamboat Bells, TAVERN AND LAND BELLS, GONGS, FIRE ENGINES, FORCE AND LIFT PUMPS.

Steam, Liquor, Soda, Oil, Water and Flange Cocks, and Valves of all descriptions, made and repaired. Hose and all other Joints, Spelter, Solder and Copper Rivets, etc. Gauge Cocks, Cylinder Cocks, Oil Globes, Steam Whistles. HYDRAULIC PIPES AND NOZZLES for mining purposes. Iron Steam Pipe furnished with Fittings, etc. Coupling Joints of all sizes. Particular attention paid to Distillery Work. Manufacturer of "Garratt's Patent Improved Journal Metal." Highest Market Price paid for OLD BELLS, OOP-ER and BRASS. 6-1f

NOTICE.

We certify that the partnership of Dewey & Co., doing business in San Francisco, California, is composed of Warren B. Ewer, George H. Strong and John L. Boone, all of whom reside in the city and County of San Francisco, and Alfred T. Dewey, who resides in Oakland, Alameda County, Cal.

San Francisco, Cal., June 3d, 1874.
WARREN B. EWER,
GEORGE H. STRONG,
JOHN L. BOONE,
ALFRED T. DEWEY.

STATE OF CALIFORNIA,)
 CITY AND COUNTY OF SAN FRANCISCO.)
 On this 3d June 3d, 1874, before me, F. O. Wegener, a Notary Public in and for said City and County, personally appeared Warren B. Ewer, George H. Strong, John L. Boone and Alfred T. Dewey, known to me to be the persons whose names are subscribed to the within instrument, and acknowledged to me that they executed the same.

Filed June 5. **W. HARNEY,** County Clerk,
 By **W. STEVENSON,** Deputy.
 In witness whereof I have hereunto set my hand and affixed my official seal, the day and year first above written.
 jm6-4t **F. O. WEGENER,** Notary Public.

ANDERSON & WOODS'

AMERICAN CAST STEEL.

Price, 18c. per lb.!

Every Bar Warranted and Guaranteed equal to any English Brand.

HOOKE & CO.,

Sole Agents for the Pacific Coast.

117 AND 119 CALIFORNIA ST., SAN FRANCISCO.

Brittan, Holbrosk & Co., Importers of
 Stoves and Metals, Tinners' Goods, Tools and Machines;
 111 and 117 California St., 17 and 19 Davis St., San Francisco, and 118 J St., Sacramento, mr.-1y

MINING AND SCIENTIFIC PRESS

An Illustrated Journal of Mining, Popular Science and General News.

BY DEWEY & CO.,
Patent Solicitors.

SAN FRANCISCO, SATURDAY, JUNE 13, 1874.

VOLUME XXVIII
Number 24.

Swingle and Huntington's Improved Breech-loading Fire Arm.

As an example of the progress which can be made in any branch of industry, when an incentive is offered to inventors, we refer to the improvements which have been made in fire arms within the past fifteen years. The improvement in loading fire arms at the breech, instead of at the muzzle, shortened the process so much that the old muzzle-loader went almost entirely into disuse; but recent improvements have gone so far as to enable the "shootist" to load his gun without taking it from his shoulder, and with only slight disarrangement of his aim.

The accompanying illustration represents a repeating fire arm, which is the invention of Messrs. Alfred Swingle and Frank A. Huntington of this city, and which has been protected by several patents secured through the MINING AND SCIENTIFIC PRESS Patent Agency.

Being a California invention, we have a pride in saying, that we believe it superior to any other fire arm yet invented. It is at once extremely simple, strong, convenient and safe.

As will be readily seen, the invention belongs to that class of fire arms which is known as the "Sliding Barrel Breech-loaders."

The stock has a U-shaped extension which projects from its lower side. Upon this extension the barrel rests and slides when it is moved forward to load the gun. A cap or housing, B, on the under side of the barrel covers the outer end of the extension when the barrel is drawn back. This housing is in the proper position to be grasped by the left hand when the gun is aimed, so that a simple stroke brings out of the arm operates the barrel. When the barrel is drawn back it is locked in place by a U-shaped lever, C, which has its forward end pivoted to the slide or extension of the stock just in rear of the housing, B. The trigger guard is attached to or forms a part of the housing, C, so that when the finger of the right hand is inserted in the ring, D, of the trigger guard; a slight movement of the finger downward will depress the rear end of the U-shaped lever and allow the barrel to be moved forward. The upper edge of the rear end of the U-shaped lever is provided with a recess and shoulder upon each side of the barrel, which is shown plainly in the engraving. On the rear end of the barrel is an enlargement which abuts closely against the breech block when the barrel is drawn back, and thus when the lever, C, is forced upward, the recess in the U-shaped lever forms a clamp or lock for drawing and holding the barrel and breech block together. This movement is very simple and easily understood. The U-shaped lever is locked in place when it is drawn closely up against the barrel by a latch which is connected with the ring of the trigger guard, and which is operated by the finger, usually the second finger of the right hand.

This magazine tube, in which a supply of cartridges (usually seven) is contained, extends along inside of the stock from the butt end, and opens below the rear end of the barrel into the gutter of the U-shaped extension upon which the barrel slides. In this gutter the inventors have arranged a rocking lever, which they call a "comb-and-fetch-it," from the peculiar manner in which it operates to receive a cartridge from the magazine, and lift it into line with the bow of the barrel. This lever is pivoted at its middle in the gutter, and has a lug or toe at its for-

ward end, while its rear end has a saddle formed of two spring clasps, E, secured to it. This saddle is of the proper size to receive and hold a cartridge. When the barrel is drawn back against the breech block, the saddle, F, is forced down into the gutter, so that a cartridge is forced by the spring in the magazine into it; and after the load in the barrel has been fired, the thrusting forward of the barrel extracts the shell of the discharged cartridge by means of a shell extractor, properly located at the breech, and also by coming in contact with the toe on the forward end of the rocking lever raises the saddle or opposite end of the lever sufficiently to bring the fresh cartridge in line

one notch is made at the half, and the other at the full cock. A spring is arranged to force the stem upward so as to enter the lug in the notches when it comes opposite to these. Thus when the gun is at a half cock, the hammer is locked so that it cannot be drawn back until the head, I, is pressed upon with the thumb. This releases the lug from the notch, when the hammer can be drawn to the full cock where the lug enters the full-cock notch. A wedge, which is arranged so that it will be projected forward between the lug and notch, by a pull upon the trigger serves to release the lug in firing the gun; the entire arrangement being exceedingly simple, as the en-

SWINGLE AND HUNTINGTON'S REPEATING RIFLE.

with the bore of the barrel; thus, when the barrel is drawn back again, the point of the cartridge will enter the bore and be forced out of the saddle and driven into the barrel, while the saddle is forced down again into the gutter ready to receive a fresh cartridge.

G is a telescopic extension on the rear end of the barrel, which enters a corresponding recess in the breech piece when the barrel is drawn back, so that an absolutely gas-proof joint is made, and the danger of powder blowing out at the breech, as is usual with other breech-loaders, is in this way entirely avoided.

The tire lock is composed of only three pieces. This safety lock is very necessary, as the frequent accidents which occur by the accidental springing of the hammer will testify. The firing pin used is so constructed that when the cartridge is exploded by the hammer driving the pin against it, the explosion which follows will force the hammer to the half-cock notch and lock it, thus providing for the possible forgetfulness of the person carrying the gun.

The inventors have applied several other improvements in this gun which are important and useful—in fact we may call it a new gun, as

SWINGLE AND HUNTINGTON'S BREECH-LOADING SHOT GUN.

The cartridges in the magazine tube can be arrested and prevented from leaving the tube by a stop arrangement which is operated by moving the button, H, up or down. This button, as shown, is within easy reach of the forefinger of the right hand. Thus when it is desired to use the gun as an ordinary hand breech-loader the button is moved downward so as to arrest the movement of the cartridges, when the gun can be loaded by inserting the cartridges by hand when the barrel has been carried forward; but in case it should be necessary that several shots be fired in quick succession, a movement of the finger raises the button and allows the cartridges to feed out as a repeater. By this arrangement a reserve of seven shots can be carried in the magazine, ready to be used in case of necessity, while the gun is used as a hand breech-loader.

Messrs. Swingle and Huntington have also patented a safety lock which they also apply to their breech-loaders. A stem passes down through a hole in the hammer, on the upper end of which there is a button, I. Below the hammer a lug is formed on the opposite end of the stem and this head enters notches which are made in the side of the slot in which the hammer moves;

the detail of every portion have been altered and adapted to the new arrangements.

We also present an illustration of a shot gun which is provided with Messrs. Swingle and Huntington's improvement. This gun we know will please the sportsman. It is loaded by hand, the barrels sliding forward in the same manner as described for the rifle, and it is provided with the same locking device.

Messrs. Swingle and Huntington have been very persevering in their efforts to provide a superior fire arm, and we believe that they have succeeded. We shall speak of this invention again. In the meantime the inventors are pushing its introduction, and we wish them success.

Suit has been brought in Pioche by the Magnet Mill and Mining Company against the Page & Panaca Silver Mining Company, for the recovery of certain mining ground described in the complaint. An injunction was also prayed for, prohibiting the defendants from working the disputed ground until the termination of the suit. On filing a bond conditioned in the sum of \$10,000, a temporary restraining order was issued, returnable on the 12th instant.

Public Documents for Miners.

We see by the telegrams from Washington that Congress is deliberating on the question of providing for the sale of extra copies of public documents, and for the distribution of the regular official editions. One section of the bill provides for the printing and distribution by the Commissioner of Agriculture of 25,000 copies of the Agricultural Reports. An amendment was afterward offered and agreed to, increasing the number to 300,000 copies.

We do not know whether the bill makes any reference to the reports of the U. S. Mining Commissioner, or whether any provision is to be made to increase the edition of that work, or provide for the sale of extra copies. It is to be hoped, however, that it does. After all the "tinkering" with the mining laws by Congress this session, they have probably been made aware officially that there is such a thing as a mining community, as well as an agricultural community in the United States. If they have at last had this impression forced upon them, it would be well for them to consider that there is also a Mining Com-

missioner, who publishes an annual report, and that this report may be of interest to these miners; that it may contain valuable information which these miners ought to be possessed of, and that there ought to be some means by which these miners could have these reports. If there was only one book to one hundred miners, it would not be so bad, but there is not.

A very small edition of this report is printed, somewhere between 1,500 and 3,000 copies. A few hundred of these books find their way to this coast, and nobody knows where the rest go to. The Mining Commissioner can not get hold of enough of them to send to people who have furnished articles for the work gratuitously, which creates considerable dissatisfaction among them. As by far the greater proportion of the report is contributed by parties resident on this coast and without compensation, after a year or two more they will decline to write, and the report will necessarily be a meager one. The appropriation is so small that the Commissioner is unable to travel much or employ many assistants. We have received so many letters since the last report was issued, asking where the work could be procured, that we are certain that a much larger edition would be acceptable. We have had, heretofore, to rely entirely on the probability that a private publishing house would issue the work from the Government plates, which has usually been done. Whether it will be done this year or not, we do not know. But it seems rather strange to print 300,000 copies of the Agricultural Reports, and only 3,000 of the Mining Reports. Of course there are more farmers than miners, but so great a discrepancy in the number is not just to the mining interests. An interest which produced out of the ground over seventy million dollars in 1873, and over sixty-two million dollars in 1872, is surely worthy of at least one public document in a year. Let us have more of these reports, or print an extra edition, and print them at a price so that they will be within the reach of all.

QUICKSILVER has been discovered in the mountains back of Borlitos, Santa Cruz Co. A number of claims have been located and a company has been formed to work one of the claims.

CORRESPONDENCE.

Mining in Plumas and Sierra Counties. No. 8.

[By Our Special Correspondent.]

After leaving Port Wine we pass down the eastern side of Slata creek until we come to Poverty Hill.

Why this place received the name it bears, I am not informed; it certainly could not have been from its poverty. The first company encountered, on our westward course, is that of Kingdom & Bros. Their claims are hydraulic. At the present time of writing they have but one pipe in operation, (a monitor), but I understand they intend to add another as soon as they conveniently can. Of the extent of this company's ground I cannot inform your readers, as I am not informed myself. Adjoining them are the claims of Westall & Co. Theirs are also piping claims and great results are anticipated by the company when they clean up. They, like Kingdom & Bros., own their water rights, thus saving them a heavy tax for the aqueous fluid.

The Gold Valley Company

Are driving their tunnel ahead through rock that can almost be called flint rock, it is so hard. They are in now about 1,000 feet, and expect to get it completed this spring. Hugh Smith, and his brother William, are two of the owners. I believe that capitalists in San Francisco own a controlling interest. There are a great many companies, whose claims are lying dormant, waiting for the company to finish their tunnel, as they will then have plenty of fall to wash their dirt through the tunnel. Poverty Hill, poor in name, is certainly rich in gold.

We will now take a walk from here over to Scale's Diggings

And see what our friends are doing there. I will start off first with Col. Williams & Co., who have 500 feet of bed-rock tunnel, and 4,000 feet of flume. Their banks of earth (60 feet in height) are knocked down by two Little Giant pipes. Their under-currents are A No. 1, of which there are two. They use about 1,000 inches of water through both pipes. The Col. resides in Oakland, I believe. The mine is in charge of superintendent Robert Williams, Esq., a gentleman who is not only highly esteemed by the company, but by the public, wherever he is known. Mr. Williams also has charge of the company's claims at Council Hill.

The company here have a ditch 12 miles in length, with 600 feet of flume, 40 feet in height. Their two reservoirs have a holding capacity of 5,000 inches of water each. Their under-currents, of which there are two, are of the best, while two Little Giants, with a pressure of 300 feet, and 600 inches of water each, crumble away the banks, and send them seaward, to fill up the Yuba and Sacramento rivers, with their useless dirt, after the golden treasure it contains has been extracted therefrom by the ingenuity of man. Returning to Scale's Diggings, we will poke our long nose into

Boyce & Bro's

Diggings at Fairplay. They obtain their water from Rock creek, conveyed in a ditch three miles in length. Two Little Giants, using 800 inches of water, make sad havoc with the works of nature. Stephen Boyce & Bro. are the lucky owners of this valuable mine. C. W. Hendel, United States L. M. S., informs me that the brothers made a clean-up, after a short run recently, and realized the snug little sum of \$15,000. Stephen Boyce also owns in the hydraulic diggings at

Marion Hill,

Just below Scale's Diggings on the road to Strawberry valley. The company is known as Joe McChesney & Co. One Little Giant is used in these claims, but I think it a big giant, the way it knocks the banks of earth down. I intended to give a description of Brandy City and its mines, but will wait till my next, for want of reliable information. I wish to explain one thing to your readers; I will not on any occasion write anything in these letters that deviates one iota from truth if I know it. I am the trusted correspondent of your journal; and as such, I will not lend the use of my pen to falsehood. I stated to you that if I could not give you facts, I would say nothing at all. So far, I have kept my pledge, and will continue to do so. I merely speak of this to avoid further annoyance from any parties wishing me to pander to their interests, either for or without pay, for I will not do it. There are some of your readers, who will, when they see this, understand its meaning. Whenever you consider my letters unreliable, throw them into the waste-basket, where all articles of that nature should go. I find it very hard work to obtain news, as those from whom I wish to glean my information are quite reticent in giving it. With these remarks I will close this short letter.

MAXIMILIAN.

The rollers used in an improved crushing and grinding machine being furnished with scrapers and knives, will prevent any clogging, a desideratum, especially for cocoa and sugar, not hitherto obtained.

Quicksilver in San Luis Obispo Co.

A correspondent of the San Luis Obispo Tribune says: On reading a notice of the developments in cinabar being made near Csmbria and at the Josephina mine, I thought it would be of interest to your readers to give you some particulars in regard to the progress being made in the Pasedor Colorado district, situated about 10 miles from Santa Margarita post-office, and four miles from the flourishing settlement of San José. Having business at San José valley, and hearing so many reports of those "vains," their prospective development, richness, extent, permanency, etc., I propose to give you a slight description from my personal examination.

These veins or deposits are called the

Tres Amigos,

And lie parallel to each other, upon a spur of the Santa Lucia mountain (a portion of the Coast range), which, in this immediate vicinity, runs in a northerly and a southeasterly direction; the veins, or deposits (more properly called) appear to lie with the course of the spur.

Extent.

There are four locations of 1,500 feet each, which were located some 15 months since, under the Mining Laws of the Act of Congress, passed May 10th, 1872, upon the spur as referred to above, which I should judge to be about 2,000 feet above the Rinconada valley.

Present Developments.

From the croppings facing upon the west side of the spur, I found an excavation of 120 feet in length by an average depth of 40 feet, and width of 60 feet, showing cinabar, which lies beneath a stratum of serpentine, forming a wall upon the north side, and upon the south, as far as prospected, a kind of conglomerate mixture of cinabar and limestone; but from croppings not yet developed, I should judge will eventually, when prospected, be found of a serpentine formation, thereby forming a perfect chimney of ore.

Tunnels.

About sixty feet below the developments above referred to, the Livermore tunnel is being run now on a depth of 100 feet; also the Tres Amigos tunnel, about 150 feet below still, now in a depth of 80 feet, which are intended to strike the center of the chimney, which show ore in small quantities, called threads or feeders, evidently giving indications of permanency. There were also quite a number of prospects, such as open cuts, shafts, which, the superintendent informed me, had been made before this valuable property changed ownership, all of which showed more or less ore.

Character of the Ore.

Upon examination of the ore upon the dump, on the occasion above referred to, I think it will fully average from 5 to 8 per cent., of which there is quite a pile.

Mining and Smelting Facilities.

Immediately at the base of these deposits, say about 1,000 feet, a fine spring of water, containing about $\frac{1}{2}$ an inch, miners' measure, flows, as well as the water of the Rinconada creek, about $\frac{1}{2}$ a mile off, running through a tract of wood composed of live oak and pine, being a portion of a tract lately purchased by the present owners, containing one hundred and sixty acres; which I am informed it was the intention of the owners to utilize immediately, thereby ignoring the music of the celebrated song, "Woodman Spare that Tree;" from which fact I judge the present owners of these deposits are evidently aware of the permanency of their investment.

This Magnificent Property

Is now employing twenty-five practical miners, mostly from the New Alajaden and Idria mines, under the general superintendence of Don Estevan Castro, (one of the original discoverers) all of whom seem to take an individual interest in the prospects of this enterprise; and I must say, from previous observations of mines in Nevada and Arizona, fully understand their business in all its details.

There are other Veins

Or deposits, located in this district, I learned, but not having time to examine them, can give no report. I have been informed since my return, that another very extensive deposit has been found, about two miles from Tres Amigos Co.'s claims. In conclusion I would state that at no very distant day, the port of San Luis Obispo will be able to make a fine showing of quicksilver among its many articles of export.

THE STICKER MINES.—The Portland Oregonian publishes the following extracts from a letter written to a citizen of Portland, dated from Wrangel May 26: "The river opened about the 23d of April, and the bottom of the mines dropped out about the same date. The very first day after the river opened about 100 disgusted men started back for Wrangel. From that time up to the date of the letter they were coming down almost every day. About 800 men are at the mines and scattered along the river; but the writer says that within a few weeks there will be considerably less. Most all who went up are becoming disgusted, and are anxious to return. The general impression prevails that these mines are a first-class blirk. A good many who arrived at Wrangel are 'dead-broke,' having expended everything in coming down. The writer says there are a few claims which are rich and yield well, but there is no extent of country. Every steamer which leaves Wrangel is carrying away great numbers of men."

The Sumner Mine.

While at Kernville recently, we found that new energy had been infused into the mining interests of Kern county, partly by the new discovery of rich leads, and partly, perhaps, by the success which has attended the opening of the Sumner mine, under the management of capitalists and competent mining engineers, who have prospected the lead to the extent that justifies the construction of an eighty-stamp mill, the machinery for which is already being laid on the site selected for its erection, the stamps being 750 pounds weight, and capable of crushing 100 tons of ore per day through fine screens.

The water power is abundant for several mills, should the future development of the mine require them, which is not improbable from the fact that the company now have a United States patent for nearly two miles in length on the lead; notwithstanding which they will, the coming season, construct a large ditch, about ten miles in length, at a cost of \$40,000 or \$50,000, carrying the water to the top of their main shafts, so that the whole of their mine may be worked by water, the pumping out, hoisting and reduction being done by the same power, ensuring the cheapest mining and milling done in the State.

The mine being owned and backed by such men as John P. Jones and John O. Earle, we may reasonably expect, at no very distant day to see hundreds of stamps and a small army of men employed in the operation now before us.

Many extensive improvements for cheapening the work are in contemplation, some of which will not be introduced at present, though we understand a tramway with T rails will be laid from the mine to the mill for the delivery of ore in cars, using horse power, and pumping and hoisting engines adapted to the capacity of the new mill will soon be put up, it being the intention to continue sinking the main shaft for new leads.

The company have a new road now nearly completed to Greenhorn mountain via Waggy's Flat, to a large saw mill which is now in course of construction. This road will be continued to Bakersfield, bringing Kernville within fifty miles of that place, by a good road. It is plainly to be seen that the work now in hand is destined to change the whole business of this section, as it will give encouragement to other enterprises, some of which are being quickly developed, and to which we intend to give attention at another time. —Visalia Delta.

MINES OF NOVA SCOTIA.—The Commissioner of Mines has made his report on the mines of Nova Scotia in the year 1873. There were twenty-eight coal-mines in working operation. From these were turned out 1,051,467 tons, of the value of \$2,699,347. The price in the course of a single thralve-month rose from \$2.25 (free on board) to \$3.50. The produce has increased from 673,242 tons in 1871 to what we have already mentioned in 1873. The Commissioner calculates that in all probability the output for 1874 will amount to at least 1,250,000 tons; in all likelihood it will be much larger. The chief consumption was in the home market, but 264,760 tons were exported to the United States. It is curious to notice that while the United States exported in 1873 to the West Indies 47,708 tons of coal, of which 36,363 tons were bituminous, or what is produced in Nova Scotia, the Nova Scotians managed to the same quarter only 1,538 tons, while Great Britain sent during the previous year to these same West Indies 147,997 tons. The gold mining for the year presents no noticeable feature. The yield has been smaller, and the modes of working the mines are still so primitive as to cause no surprise at the comparatively unsatisfactory results. The yield was 11,852 oz., valued at \$219,270, from 17,708 tons of quartz. Iron was produced in small quantities. The two iron works of Acadia and Annapolis were not worked continuously, and between them produced only 1,226 tons of pig metal. The total iron produce of the mines of Nova Scotia in the year was 3,485 tons, of the value of 10,455 tons.

LIFE-BOAT STATIONS.—The House has passed the bill to provide for an establishment of life-saving stations and homes of refuge upon the sea and lake coast of the United States. The life-saving stations to be established on the Pacific coast are as follows: Washington Territory, at Neah bay, Shoalwater bay and Cape Oiza; Oregon, at Capa Rajo, a life-boat station; California, Humboldt bay, Point Reyes, between Point Lobos and Point Pedro, and Point Conception, near the lighthouse, life-boat stations. The Secretary of the Treasury is authorized to employ crews of experienced surf men at such of the life-boat stations on the Pacific Coast as he may deem necessary and proper, for such period and at such compensation, not to exceed \$40 per month, as he may deem necessary and reasonable.

THE SAN FRANCISCO COPPER MINING COMPANY, operating near Spencerville, a few miles east of Wheatland, have new furnaces built, and commenced operations last Monday. They have put a new pulsometer pump into the mine, which works well and is capable of handling all the water in the mine.

RICH developments have recently been made in the Hercules and Live Oak quicksilver mines, located near Cloverdale.

A LARGE body of ore has been struck in the Rattlesnake quicksilver mine at Pine Flat.

Jersey Mining District.

Jersey district is situated in Lander county, near the northeast corner of Churchill county, and is distant from the town of Galena 40 miles, and from Battle Mountain, via Galena, 55 miles, and from Viock's station, on the Austin stage road, only 20 miles. The district was organized about two years ago, and work has been going on by the original locators for the past two months, but the rich ledge was discovered about two weeks ago by Lan. Trimbla, who was following a trail at the base of the mountain, and who discovered a piece of ore weighing about 40 pounds, which had recently been broken by a horse stepping on it. This piece proved to be rich in galena, and Trimbla immediately commenced a search for the ledge from which it came, and, after about nine days' prospecting, found what is now known as the Trimbla ledge, and is about a mile from the company's old works.

Robert McBeth reports the ledge as well-defined, with a granite head-wall and quartzite foot-wall, the ore streak being four feet wide, but it measures eight feet on the surface, owing to the dip of the ledge. Mac. says there are at least 500 tons of ore on the surface, and all alike. As far as assays had, the ores go as \$30 in silver per ton, and 57 per cent. in lead. McBeth believes that in a short time it will prove to be one of the richest strikes in Eastern Nevada.

The first locations consist of 3,000 feet on the course of the ledge, owned by Lan. Trimbla, James McKay, Joseph Parks and Capt. Taylor, of Galena.

The ledge can be traced for a mile, in a southerly direction from the original location, but shows mineral only in two localities—to wit, on the original location and on the locations owned by McBeth, B. F. Wilson, Samuel Timby, and Robert Smith, whose location is 6,000 feet south of Trimbla's discovery. The mines are situated between two creeks, about $1\frac{1}{2}$ miles apart, in either of which there is sufficient water for mining purposes, and the surrounding country is tolerably well timbered. —Measure for Measure.

ALPINE MINING.—European travelers are fond of narrating the perils of the ascent of the Alps amid eternal snow and ice, yet in the American territory of Colorado, mining is carried on all winter on Mount Lincoln, at over 14,000 feet above the sea level, the height of the Jungfrau Alp in Switzerland. In the latter country the forests of pine timber disappear at an altitude of 6,000 feet above the sea level, but in Colorado they only give out at an altitude of 11,500 feet. Much of this difference arises from the fact that Colorado is in latitude much south of Switzerland, but the country is also remote from ocean vapors, and the ascent to the foot of the mountains is very gradual. Certain it is that in all parts of the vast interior mountain regions settlements are flourishing and mining and agricultural operations are carried on at altitudes that would be uninhabitable in Europe. There are settlements in Wyoming that are 8,000 feet above the sea level. The climate in all that vast region bears no analogy to that of the Atlantic States, being mostly dry and healthy, and not liable to the torrid heats of midsummer.

A STEAM QUABBER.—We find in the London Builder a description of a machine invented for quarrying and removing blocks of rock. The machine is in operation at the granite quarries of Lochfynsida. Hitherto, in connection with the system of large blasts of 40,000 to 80,000 tons at one explosion, the innumerable large pieces of rock got wedged together to such an extent as to render it a work of great difficulty and danger to get them moved out from the mass of rock on the quarry floor. The quarrier has been supplied by Messrs. Napier Brothers, from a modification of their patent purchase steam windlass for the lifting of ships' anchors. At the outer extremity of the area of the quarry floor, the sole-plate, occupying a space about six feet square, is bolted down to the solid rock, and the whole superstructure above this is only, over all, about nine feet in length, by eight feet in breadth, and four feet in height. Steam is admitted into a pair of nine-inch horizontal cylinders, and by means of a small auxiliary drum the chain cables are carried up to any given point on the quarry face. Arriving there, the chain is attached to the block of stone required, the purchase windlass is then set in motion to heave in the chain, and, according to test, moves off a block of granite forty tons in weight with great ease.

THE WOODVILLE MINE.—The billion yield of the Woodville mine for the past nine months was \$30,220. During the same interval, \$133,000 in assessments has been collected. The disbursements for the same period have been \$160,042, including \$36,533 for debts previously contracted. The present liabilities are \$17,000 for additional machinery sent, and \$5,500 for mine expenses in May. The amount of cash on hand is \$3,200. An assessment of \$28,000 was levied on the 23d ultimo to remove these outstanding obligations.

Most of the platinum which finds its way into the market is produced in Russia, the product, however, being very small. The total production for 1871 was 4,100 pounds. It is worth \$75 per pound. Being of great hardness and almost indestructible, it is very useful in the construction of standards of measurement and instruments for scientific purposes.

SCIENTIFIC PROGRESS.

The Time Taken in Nerve Telegraphy.

The interval between the action of a stimulus on the organ of sense and the conscious reaction is termed by Exner the "reaction-time." This he endeavored to measure in a large variety of cases. The recognition of the impression was generally indicated by pressing a key with the right hand. Both the stimulation of the organ of sense and the responsive pressure of the key produced marks on a blackened cylinder turning at a known rate; so that the interval of time between the two could be estimated by the space between the two marks.

Experiments were made on persons of various ages and temperaments,—one of them a feeble old man of 76 years—the interval being noted between the stimulation of the left hand by an induction shock and a signal in response with the right hand. The reaction-time varied from .1,295 of a second to .3,576 of a second, or roughly speaking, from about one-eighth to one-third of a second. It would seem that, as a rule, the shortest time is to be looked for in persons who have formed the habit of concentrating their attention on an object, depending upon this rather than upon age.

Different methods of measurement give corresponding results with different persons; that is, if one method gives a shorter reaction-time than another method with one person, it will give a shorter time with all the other persons. The shortest reaction-time was obtained when an induction shock was sent through the eye, producing the impression of a flash of light. The next shortest was when an electric shock was given to a finger of the left hand; the next, between a sudden sound and the signal that it was heard. Then follow, in order of quickness, the responses to an electric shock to the forehead, and to the sight of an electric spark; and last and slowest, that to a shock of the toes of the left foot. It is a noteworthy fact that Donders measured the reaction-time for three of these cases, and found the order the same.

Of the circumstances that affect the reaction-time, the most important is the intensity of the stimulus, weak stimuli giving more discordant and generally larger numbers than strong ones. The concentration of the attention comes next in this respect. The reaction-time diminishes with practice, but fatigue increases it. In a long series of experiments, the last results are commonly larger than the first. The taking of tea or of a small dose of morphia did not affect the reaction-time.—*Jour. of Chem.*

FRACTURE OF METALS.—In the course of a paper on the character of metals, Prof. Thurston says: A kind of fracture, which is probably always indicative of brittleness is generally, and possibly correctly, termed crystalline. It is supposed to be produced by a long continued succession of shocks, which, entraining the metal to the elastic limit, permit the crystalline grouping of molecules to take place. Dr. Percy, the leading metallurgical authority of the world, seems to have been fully convinced of the possibility of the formation in this way of true crystals; but direct experiment is still desirable fully to determine it. A singular instance of this peculiar molecular action recently occurred at the Morgan Ironworks, New York. While a powerful steam hammer was at work upon the red-hot end of a very large shaft, originally designed for the engines of a large naval steamer, a piece of the opposite end, which was cold, and which was supposed to be strong enough to transmit several thousand horse-power, dropped off. This was an extraordinary event, but not unprecedented. In all such instances, the fracture seems to follow a plane passing through a comparatively sharp angle at the side of a collar or at the end of a journal.

Though nearly all solids expand by heat, they do so to very different degrees. Even members of the same class, such as the metals, exhibit this difference. A band made up of a sheet of brass, welded to a sheet of iron, bended into an arc when heated, the brass taking the outside of the arc, because it expands more than the iron. So by taking a long spiral ribbon, made by welding a platinum on to a silver ribbon, a sensitive thermometer is formed, which twists and untwists as it is heated or cooled.

M. GRUNER, France, has been engaged in measuring the quantity of heat needful to effect the fusion of cast iron slags, dross and steel, in order to compare the heat produced in blast furnaces with the heat utilized. He finds that cast iron melts at from 2,664° to 2,874° Fah. The heat of a hot blast iron furnace, for cast iron, is ordinarily reckoned at 3,092° Fah. Beesmer steel, according to M. Gruner, melts at 2,912° Fah. Siemens estimates the heat necessary in a furnace to melt steel at 3,600° Fah.

As an electric indicator of vitiated air, says the *Gaceta Industrial*, a solution of palladium chloride is so connected with a battery that, as long as no metal is precipitated, no current passes; but as soon as carbon monoxide occurs in the atmosphere, metallic palladium is precipitated, which establishes a current, and rings a bell to give warning of the presence of the noxious gas.

Mineral Waters.

On its long subterranean travels water generally meets with substances which it can dissolve. Even the ordinary spring-water is therefore chemically not as pure as rain-water; and, although the carbonate of lime which it contains in solution is found in it only in small quantities, they are nevertheless sufficient, in contact with soap, to form a fishy lime-soap, while in rain and river water the soaps are uniformly dissolved. It is also sufficient to prevent the swelling of boiling peas and beans, since the lime attaches to the skin and prevents the access of water. On that account spring-water is called hard, in contrast to soft river-water. The spring is converted into a mineral spring when it contains mineral matter in solution to a greater amount.

Regarding the formation of mineral waters, Pliny long ago pronounced the important fact: the waters are as the land through which they flow. Starting from this point of view, Struve examined the different varieties of rock in the vicinity of Carlsbad, and after having discovered in them all the solid constituents of the neighboring mineral springs, he attempted their artificial imitation by bringing the pulverized minerals under the pressure of a pump in contact with carbonic acid gas and water. His experiments were crowned with success, and the artificial mineral waters which he thus produced have proved to be of great benefit to suffering humanity, especially in regions at a great distance from natural mineral springs. The ocean is the mightiest mineral spring of the earth; but the uniformity of its composition, regulated by evaporation, external access of various substances and organic processes, can be fully understood and appreciated only by following the further wanderings of the water gushing forth from springs, in the form of brooks, rivers and streams, over the surface of the earth—a theme which exceeds the limits of this discussion, and is deserving of a special investigation. It is thus the directly visible complementary link in that circular course of water, the first movements of which have so long been misunderstood, because going on in the air and under the ground, and thus being hidden from the observation of man.—*Gastlight Journal.*

PRECIPITATION IN FRESH AND IN SEA WATER. It is a curious fact that the deposition of sediment is much more rapid in sea water than in fresh water. At a recent meeting of the Royal Physical Society of Edinburgh, some experiments made to determine the comparative rate of deposition in the two cases were described by Mr. David Robertson. The reader can satisfy himself that the precipitation really is quicker in the sea water by a simple experiment. Let him take two glass jars of equal size, and fill the two about four-fifths of their depth, the one with sea and the other with fresh water; then fill both up with clay dissolved in fresh water—say, about the consistency of cream—and stir both well up. Set the jars side by side to settle, and in a very short time the precipitation in the jar containing the sea water will be seen to be going on rapidly, while in the jar with the fresh water little or no change will be observable. From these results, it is evident that rivers running into the sea will deposit their sediment nearer their mouths than if they empty into fresh water lakes, and are, therefore, other things being equal, more likely to be obstructed by bars.

THE CENTENNIAL OF CHEMISTRY.—It has been suggested by a correspondent of the *American Chemist* that the year 1874 be accepted as the Chemical Centennial, and celebrated as such. Of course chemistry has no definite birth-day, but so many important discoveries were made in 1774, and that year was so noted for remarkable activity in the progress of the sciences, it is suggested that the foundation of the modern science of chemistry may be dated from that period. The editor of the *Chemist*, in view of the fact that centennial celebrations are now in order, approves the suggestion, and seconds the proposition that American chemists should meet on the first day of August next, at some pleasant watering-place, to discuss chemical questions, especially the wonderfully rapid progress of chemical science during the last hundred years.

THIRTY-SEVEN small planets have been discovered in the years 1872 and 1873, or eighteen and a half for each year, making 1,850 per century. From the days of Hipparchus to the present time we may reckon 2,000 years; had astronomers worked with the same zeal and success during these 2,000 years, the number of small planets known would have amounted to 37,000, only three times the number given by Arago of stars to the 7th magnitude, and a very small proportion of the stars of the 10th magnitude. Although very minute, the latter are generally much brighter than small planets as seen at the time of opposition.

RENDERING WOOD UNINFLAMMABLE.—A recent invention relates to a novel treatment of wood for the purpose of rendering the same unflammable, which treatment also tends to preserve the wood; the said invention consists in the use of a new composition, and in the novel means employed in its application. The fluid which the inventor employs for the purpose is composed of protoxide of iron, sulphate of potash, sulphuric acid, sulphate of aluminum, hydrochlorate of soda and protochloride of iron, with sufficient water to give the fluidity required for the application.

MECHANICAL PROGRESS.

An American Coal-Cutter.

We give an account of the recent trial of the first practical coal-cutting machine in the United States. The machine is employed in the Coal Brook mine, about two and a half miles north-east of Brazil, Indiana, and is known as Brown's Monitor coal-cutter. The machine consists of a five-horse power steam engine, driven by steam carried into the mine by a steam-pipe, terminating, however, in a few feet of rubber hose, which permit of full freedom of motion to the machine. The intention of the proprietors is to employ compressed air in place of steam as soon as their experimental trips are finished. The cutting arrangement is an iron rim of four feet in diameter, which has on its periphery movable steel teeth, placed at points about 12 inches apart. These teeth may be taken out and ground whenever they become dull. This rim lies on small wheels which support it, and allow a free motion, and has cogs on its under surface which gear into cogs on a shaft turned by the engine. By this means the power is applied near the circumference of the wheel, instead of at the center, as in the ordinary circular saw. The principal reason for this arrangement is to get a deeper cut at the coal. The cutter can be put to a depth of three and one-third feet or seven-eighths of its whole diameter, whereas the ordinary circular saw can scarcely cut to one-half its diameter. The machine runs on a movable track, and is fed by means of a screw working in cogs. The track is put down along the side of the coal at the proper distance from it, and when a cut has been made the whole length, the machine is put on tracks and wheeled to the next room, where the track is laid as before, and so on through the mine. The duty of the machine is put down at about a yard in five minutes. The estimate of its economy given by the proprietors is, that it saves about 35 cents per ton over the cost of putting out coal by hand labor, which, in a mine turning out say 200 tons a day, amounts to a saving of \$70 a day.—*Gas Light Journal.*

THE FIRELESS LOCOMOTIVE.—The *Chicago Times* gives the following account of the fireless locomotive, now in use on the tramways of that city: It consists of a boiler, eight feet long by three feet in diameter, and the usual machinery on a small scale. There was no fuel, no fire, no fireman. The steam was supplied for the round trip of six miles before starting. At the depot was a supply boiler, sixteen feet by three feet, in which steam was generated until 200 pounds pressure was indicated by the steam gauge. The locomotive boiler was three-fourths full of cold water. Instead of boiling this by means of a fire, and raising the pressure to a required height, the steam was introduced from the supply boiler through an iron tube. The iron tube was connected with the locomotive boiler, the latter running under the water, along the bottom of the boiler, and letting out the steam as it was freed from the supply boiler into the locomotive boiler. This steam, rising through the cold water, permeated it, and quickly raised its pressure to 170 pounds. With this supply of steam the locomotive started, drawing a heavy four-horse car, over three miles, to thirty-fifth street, in ten minutes. The amount of steam consumed represented eighty pounds pressure, locomotive starting back with ninety pounds remaining. When the starting point was reached, there were fifty-seven pounds of steam in the boiler, the pressure being reduced only thirty-three pounds in the return trip, which was a down grade. It must be borne in mind that there was a large car, heavily laden, making eighteen miles per hour. The experiment proved conclusively that, as a substitute for dummy engines, the fireless locomotive is, beyond question, a success.

SCORES OF BRICKS.—The *Colliery Guardian* thus described the process adopted by the Tee Company of Dartington, England: There is planted at the entrance of the kiln an apparatus which may best be described as a revolving table, on which are a number of wrought-iron brick moulds. A line of rails, some 20 or 30 yards, runs from the blast furnace toward this table, along which is brought the slag liquid in boxes or hoggies. These are placed in such a position that the molten liquid runs into the mould, and as each mould is filled, the table revolves round. The time required for the slag to set is about two minutes. When it is red hot the bricks are taken out of the moulds and put into the annealing kilns or ovens, where they remain for three days, after which they are perfect, cool, solid and hard, and ready for use. The company contemplate erecting an apparatus near the blast furnaces, so that the slag can run into the moulds direct, and instead of the revolving table, they are going to adopt the principle of a horizontal movement, so that the moulds will be carried along by a chain action, something after the mode of the river dredgers. The manufacture of scoræ or slag bricks is now an accomplished fact, and this new industry must tend to diminish the cost of making pig iron, wherever it is brought into requisition.

COPPER TUBES.—To manufacture solid drawn brass tubes with a copper end or copper tubes, an ingot is first cast partly of copper, partly of brass, and is afterwards drawn into a tube.

PUMPS FOR LOCOMOTIVES.—A short time ago, an apparatus was invented for supplying the tenders of locomotive engines with water, by arrangements intended to remove all risks of obstruction by foreign substances which cause such apparatus to become inoperative. This machine, as originally constructed, depended upon the automatic action of a valve in a water tank, unprovided, however, by any appliance for adjusting the valve, or affecting its automatic action by the lodgment of any foreign substance—a defect which has recently been obviated by a very simple device, the perfect adaptation and efficiency of the apparatus being, of course, still retained. In this arrangement, the valve used is either a clack, hinge or spigot valve, in combination with which is arranged a lever pivoted to the wall of the tank, or any other suitable and convenient support, and connecting with a rod extending upwards with a handle above the reservoir, in some position convenient for manipulation. For the purpose of maintaining the submerged tank in its position at the bottom of the reservoir, even when the water is entirely expelled therefrom, the eduction pipe is made to act as a stay, or special braces are affixed from the wall of the reservoir to the tank. For the attachment between the air-reservoir pipe, and the water-reservoir pipe, the coupling consists of a male part, with a collar on one end, provided with grooves to permit the passage of two hooks on the female part of the coupling.—*Ex.*

MOWING AND REAPING MACHINES.—English inventors appear to be working very vigorously to perfect existing agricultural implements, as well as introduce new forms. The feature of novelty in a new machine consists, first, in so adjusting the draught pole and driver's seat according to the nature of the crop or the weight of the driver as not to cause any undue weight to bear on the horses' necks while working, which is accomplished by having slotted holes in that part of the frame to which the draught pole is attached, so that the draught pole together with the whole of the apparatus for carrying the driver may be shifted forward or backward and thus be in a proper balance for the easy working of the horses; Secondly, in a method of adjusting the cutters and fingers so as to point up or down, as the nature of the crop to be operated upon may require, by using a lever or link upon the gear frame to adjust its angle to the draught pole. A new English patent consists in the addition, to any ordinary reaping and mowing machine, of a second or underset of the usual knives or cutters, which may either be made stationary by fixing them to the finger bar or other suitable bar, or be actuated by an extra crank and connecting rod for the purpose, although it will be understood that the upper set of knives might be made the stationary set, although this is not preferred.

METALLIC FLOORS.—A method has been devised for rendering floors in a good degree fire-proof, by employing long, flat bars of thin sheet metal, with a perpendicular flange turned on each edge. Other long, thin bars, which are curved or arched, and riveted at or near their edges to the first named strips, are placed edgewise vertically, one between each two, the connection being so arranged that the tops of the arches do not rise quite as high as the tops of the first set of bars. Narrower strips are also arranged across and riveted to the lower flanges at suitable intervals apart, to serve as lath for holding the ceiling plaster to be applied to them, as well as to brace them laterally. Similar strips are arranged across and riveted to the upper flanges, or wood pieces may be bolted on to receive and support the floor boards. The outside flanges are built into and rest in the wall; and other flanges may be applied, if desired, to the outside strip for letting into the wall. For a floor of great length the bars are lapped and riveted.—*Iron Age.*

The *English Nautical Magazine* says: The armor plates used by the Americans in the construction of their monitors were not welded together, as are those used by our own government; they were made by simply connecting thin plates together by means of rivets; thus, a 10-inch plate would be made by riveting together 10 one-inch plates. By experiment it has been ascertained that a good five-inch rolled plate is much more capable of resisting shot than 10-inch armor built up in this fashion. In conclusion, it may be remarked that it is not enough, in comparing two iron clads of similar design, to say that they each have armor of a certain thickness; the quality of the armor plates, the accuracy with which they are fitted on the ship, and the nature of the fastenings by which they are kept in place, may so affect the question as to give one ship a decided superiority over another which is said to be as strong.

IMPROVED BALE TIE OR BUCKLE.—This is formed of one piece of metal, and is made at least double the width of the band, hoop, wire or rope to be tied or fastened; it receives the strains of the band on different parts and in parallel lines; and it has portions bent sideways, or pieces projecting from the edge or side to serve as safety pieces and prevent the band from getting free. It is patented.

TURNING the past ten years, the screw has entirely replaced the paddle in transatlantic navigation, the weight of marine engines has diminished one-half, the steam pressure has quadrupled, and the consumption of coal has decreased two-thirds.—*Scientific American.*

A contract for performing the work is already let. Emerson, purchaser of the well known Drumm claim, in Happy valley, expects to commence washing next Monday. The new flume and 13-inch iron pipe are laid. All the appliances connected with the mine are first-class. Evans & McCann, engaged in tunnelling Tunnel ridge, have not got quite through the bed-rock yet. The rock is extremely hard, but they expect to knock a hole through in the course of a couple of weeks. The French company, who own the old "Boh Paul claim" in Chill gulch, are just commencing to run an incline. The tunnel will be about 450 feet long, in solid bed-rock. The location selected for running the new tunnel is down the gulch from the old one.

BANK BLASTING.—Thursday afternoon last two blasts, aggregating fifty barrels of powder, were exploded in the Dryden hydraulic mine, Chill gulch. Two tunnels were run into the bank, twenty and thirty feet in length, respectively. From the ends of the tunnels short drifts were run at right angles to them and then extended in a direction parallel with the main tunnels, the whole excavation being in the shape of the letter T. We are informed that the blasts did good execution, shattering the bank for a considerable distance back from the front and caving down a large quantity of gravel. A few lengths of the hydraulic pipe used in the mine were badly battered by the shower of rocks and cement thrown by the blast. Piping is to be recommenced immediately.

PRUSSIAN HILL.—Work is actively progressing at the Russian Hill mine, near Railroad. A new shaft is being sunk, and appearances indicate that the proprietors of the mine intend thoroughly to develop it.

The Orleans mine continues to improve as the drift is extended eastward. The ledge is over six feet thick, and every ton of the quartz will yield, at the very lowest estimate, \$100.

EL DORADO COUNTY.

MINING INTERESTS AT SPANISH FLAT.—Cor. *Mountain Democrat*, June 6: The majority of these men were here in early days, when every gulch and ravine paid pounds of gold every week, and it required but very little labor or skill to extract it. The money obtained thus easily was as easily spent, and now since they find themselves penniless, their force is gone, their energy is lost and they are living from "pan to mouth," waiting for something to turn up. "Tis true that we have two companies who are pushing their work ahead in a manner that shows their confidence in their respective claims. The Pleerville company's tunnel is now in 178 ft. They have cut one ledge 4 ft. wide and will be well rewarded for their labor. The Spanish Flat company, who have lately commenced work, are now in 40 ft. There are several large lodes directly upon the line of this tunnel which will be cut at the depth of 150 ft. or more from the surface. Now there is plenty of more room for 50 more companies, who would have just as fair prospects of success. Now we want a few energetic men who have capital or can command it, to come in here and develop it, and show it to be what it really is, one of the richest mining belts of the Pacific slope.

A REMARKABLE LEDGE.—We have been shown a specimen from the so-called "soapstone ledge" recently discovered by Leonard Reeg, about half a mile above Chile Bar bridge, on the north side of the South Fork of the American river. The specimen before us is richly studded with very bright gold, and is said to be but a fair sample of the ledge, which is from 15 to 20 ft. thick, between walls of soapstone and country slate. The gold-bearing vein matter feels and looks somewhat like soapstone, but is more translucent, has a clear greenish tint, and much of it rapidly pulverizes on exposure to the atmosphere. Our Spanish Flat correspondent pronounces it feldspar associated with granular asbestos. Others call it talcose slate.

INYO COUNTY.

COLUMBUS ITEMS.—*Borax Miner*, May 30: We are informed that the Mariotte furnace, at Sylva, will be ready for the fire on Tuesday next. The result sought is the smelting of ore without a blast.

Parties in from Lida during the week state that Gen. Page is buying up the indebtedness of the Lida mill, with the view of starting that concern to work at the earliest moment.

MARIPOSA COUNTY.

QUARTZ IN CATHAY'S VALLEY.—A gold-bearing quartz vein was discovered by Mr. Benj. Willis on his ranch in Cathay's valley, a few weeks since. It prospects favorably.

WASHINGTON MINE.—The mill connected with the Washington mine, which has been undergoing necessary repairs, recommenced running last Monday.

NAPA COUNTY.

PINE FLAT.—Correspondent *Reporter*, June 6th: The Hog's Back mines have been disturbed of late by men from different parts of the country coming on and jumping the Missouri, Lost Ledge, Geysers and Kentuck. But they were gotten rid of on easy terms, except in one case, in which I am told force had to be used. It is to be hoped it will rest here and be left to the courts to decide the case on its merits. The Oaklin Quicksilver Company, (formerly Lost Ledge) started three new furnaces on Monday, June 1st, and are doing good work.

QUICKSILVER.—Everything is looking well and work progressing at the Phoenix. Yield for month of June, 78 flasks of quicksilver.

The Reed mine sent down 19 flasks on Tuesday.

MINING ITEMS.—*Free Press*, June 6: We found the mines one of the hueiest places imaginable. Work is being pushed along vigorously, and the yield of mineral is good, and the prospects unexceptionable.

NEVADA COUNTY.

MINING AT RELIEF HILL.—Mining in the gravel claims in the upper portion of the county is now being prosecuted vigorously. The winter storm is over, the season has assumed its most favorable aspect, and water is to be had in abundance. At Relief Hill the miners are not on the great blue lead, but yet good mines are there, the gravel being the reddish brown, which frequently proves a very valuable mining ground. The principal claim there is the Eureka, upon which a tunnel of 1,400 feet in length has been driven in the last three years. During the past winter, and up to this time, the claim has paid regularly by drifting the gravel and washing it in sluices at the mouth of the tunnel. At the present time it is paying \$20 per day to the hand. One hundred inches of water are used. The Eureka Lake Water Company is also working ground at Relief Hill belonging to the company. They are now engaged on top sluicing, and are doing well. There are other claims at this camp, on some of which no work is being done at present. The water for the Relief Hill mines is supplied by the Eureka Lake Water Company, which has a large supply for this and neighboring districts.

NEVADA CITY ITEMS.—*Transcript*, June 2: The Little York Consolidated Company's claims are looking better than ever before. Some specimens about the size of a bird's egg were picked up from the bed rock the other day, and they are very plentiful.

The American Hill and the Manzanita hydraulic claims were cleaning up Monday. The Manzanita, in consequence of an immense cave, will be unable to clean up all their sluices. A large amount of gold, however, will be deposited by the two mines, and help to swell the proceeds of the county.

NORTH STAR.—*Tidings*, June 6: Report had it early this week that nearly all the employees of this mine had been discharged, and it was likely to be shut down soon. As near as we can learn, the suspension of work, even so far as it has taken place, is only temporary. It is understood that a change of management is soon to be made, and that work is impartially suspended for the better bringing about of this change.

KENTUCKY is idle at the present time, the company awaiting negotiations which are in progress in an Eastern State. These negotiations will probably secure to the company a fund sufficient to open the mine and put it on a paying basis. There must be a rich chute of ore in the Kentucky.

PLUMAS COUNTY.

LAPORTE ITEMS.—*Cor. National*, June 3: Our mines are in full blast now, there being an abundant supply of water. Gard & Orr, in their upper claims, have but one monitor at work. In their lower claims they have two at work tearing down the huge banks of earth. Immediately below, and south of Gard & Orr, are Gowell & Conly's extensive diggings. The Spanish Flat Co., under the able management of Capt. William Taylor, assisted by a huge monitor and four small pipes, are sending the gravel, dirt, rocks, etc., down Slate creekwards as though they meant business. At Secret Diggings, Superintendent Early is running two monitors, and will undoubtedly surprise those San Francisco capitalists who entrusted their property to his management, with an immense clean-up when water fails in summer. At Gardner's Point, east of Slate creek, Col. Baker has two large monitors in operation. The Pioneers, at Grass Flat, are still pushing their tunnel ahead toward the center of the hill. They are in some 3,500 feet or more. This company owns a large tract of mining property, that will, eventually, rank among the best hydraulic mining claims on the Pacific coast. At La Porte the Claybank Tunneling Co., who are running a tunnel under Bald Mountain, or in that direction, intend to tap the great mineral basin supposed to exist beneath. Their tunnel is in some 1,700 feet, all gravel and bedrock raising. There is a fine prospect of gold obtained in the gravel. The Bald Mountain Co. are also pushing their tunnel ahead.

OVER NORTH.—The North Fork Co., on Barker Hill, are running one pipe steadily, using 240 inches of water from the old Wagner ditch. They have 80 feet pressure and use a 3-inch nozzle. The water will last a month longer, and from the indications, they will clean up at least \$15,000. The same Co. are running a bedrock tunnel in the old Dutch Hill claim, and intend using the celebrated steam power diamond drills. Mr. Keddie has already surveyed 1 1/4 miles of the large ditch which the company propose to run from the Rice Creek Meadows, and also surveyed a tunnel 814 feet long, through the ridge between Butt valley and Clear creek for the ditch to pass through. The ditch will be some 20 miles long.

EAST BRANCH ITEMS.—McDougal & Co. are ground-slucing in French ravine, are doing well and have good prospects. The Taylor Hill Co. have all the modern improvements, giants, iron pipe, etc. They now have the finest bank of gravel ever uncovered in that claim; the gravel being 30 feet in depth, and prospecting uniformly and well.

SAN LUIS OBISPO COUNTY.

QUICKSILVER INTERESTS.—*Tribune*, June 6: This has been an active week in our cinnabar

interests. Two important mines have changed hands. Dr. Cochran, of San Francisco, has effected the purchase of the Oceanic mine, situated at the headwaters of Santa Rosa creek, near Cambria. The mine brought \$47,000. He is to pay \$2,000 within 30 days; \$20,000 in nine months, and the remainder in twelve months. We also learn that the Santa Cruz, known as the Frenchman's mine, near the Josephine, has been bonded by parties in San Francisco for a fabulous sum. These sales will give an impetus to our mining interests. All that is required is muscle and money to prove that there is abundant mineral wealth in this region. Time will demonstrate that our predictions are correct.

SONOMA COUNTY.

MINING ITEMS.—*Union Democrat*, June 6: There appears to be much activity in prospecting quartz leads in the county, and at those mines that are developed the preparation for getting to work is progressing as rapidly as the lateness of the season permits.

In the Soulsby mine last week a rich chute of ore was struck in the south drift, which has continued to increase from a small thread to a vein of some feet in thickness. A new mill will be erected at this mine as soon as lumber can be had.

At the Buchanan mine we learn that new battery etc., has been put in and that recently a new streak of very fine ore has been developed.

A tunnel is being run into the hill at the New Albany, which, when open to the vein, will enable ore to be taken out and the mine worked with economy.

A new mill is to be built at the Riverside, the lumber being now hauled for it. A fine grade of ore is ready for manipulation as soon as the mill is ready.

Nevada.

WASHOE DISTRICT.

CROWN POINT.—*Gold Hill News*, June 4: The daily yield is 550 tons of ore, from the 1,400, 1,200, 1,100, 1,000 and 900-ft. levels, all of which show no signs of giving out. Sinking the main incline is making steady progress.

The main south drift from the north cross-cut on the 1,400-ft. level is in 55 feet, still in ore that assays from \$250 to \$700 per ton. The ore breasts in the main west ledge on the 1,400-ft. level are yielding splendidly and looking very encouraging for the future. The ore breasts in the east ledge on the 1,400-ft. level are yielding rich ore, and are opening out with every indication of great extent as well as extreme richness. The north winze on the 1,400-ft. level has been again discontinued on account of the water, which is slowly but gradually draining. At the time of being stopped the bottom of this winze was still in rich ore.

OPHIE.—The bottom of the winze from cross-cut No. 1 on the 1,300-ft. level is still in good ore. The ore in the face of the south drift from cross-cut No. 2 on 1,300 ft. level has been considerably mixed for the past few days with porphyry, sometimes assaying well, and at others being of a very poor quality, although it now appears to be coming in more solid, and ore of a better character. The north drift from the winze in cross-cut No. 1 on the 1,300-ft. level still gives good assays, but the streak of ore which it is following is very narrow. Surveys and other preparations are being rapidly completed for the extraction of ore from the 1,455-ft. level. The incline shaft from the 1,700 to the 1,455-ft. level is to be immediately enlarged so as to increase its working capacity. The connection of the south drift on the 1,300-ft. level with the Virginia Consolidated mine is fast cooling the mine.

CONSOLIDATED VIRGINIA.—On the 1,400-ft. level the several cross-cuts are still driven ahead across the ore body. In these drifts, and in the various openings to the northward and southward of the main north winze, the ore disclosed is of a very superior quality. The ore breasts from the 1,300-ft. level upward are now yielding ore of extraordinary richness.

GOTTL & CURRY.—On the 1,700-ft. level the north drift is carried forward without cessation in the vein, and very satisfactory advancement is made. The development of the fourth station level is energetically continued. The grade of ore heretofore exposed in this level is too low to pay for extracting.

GLORE CONSOLIDATED.—The west prospecting drift at the second station in the upraise from the lower tunnel has cut the ledge, showing it to be much wider than on the level above, and the ore of greatly increased richness. This gives an almost undoubted ore development, extending a distance of three hundred and twenty feet in depth, and just how much deeper yet remains to be decided.

SUCCESS.—The necessary timber and lumber are on the ground and the erection of new hoisting works at the Grant shaft is making rapid progress.

KOSUTH.—Work in the north drift on the first station level has been suspended for the present, preparatory to resuming the sinking of the shaft for a new level.

SIERRA NEVADA.—A large extra force of workmen are now engaged in the erection of the new large hoisting building, the timbers of which are already framed and only need putting together. The pipe is laid and everything in readiness to start the hydraulic works in full blast to-morrow, though it will take one or two days after getting under way, to wash down the sides of the drain chute, so that a heavy run of large boulders will not clog the tunnel and sluices. Once under full headway with the great force and pressure, that is secured by

the great fall of the water, it is expected that an immense amount of gravel can be washed in a very short space of time. The ore bodies are showing considerable improvement in quality in the lower tunnel going west, the extent of which is not known. Daily yield 60 tons of ore.

BECKER.—There is no particular change to report of the ore-producing sections of the mine; all the ore stopes on the 1,400, 1,300 and 1,200-ft. levels are looking well and yielding abundantly. Daily yield, 550 tons of ore. The machinery of the mine is all in splendid working condition, the mills all kept steadily running, and the future of the mine looks prosperous and lasting.

HALE & NORCROSS.—The work of opening the 2,000-ft. level station from the incline has been commenced, and the incline is at the same time continued downward. The line of pumps is being extended from the 1,900 to the 2,000-ft. level. The appearance of the ground at this point is very encouraging and these deep workings are prosecuted with the utmost vigor. Some ore is also being extracted from the best looking seams on this level.

JULIA.—The increased and flattering ore developments on the 900 and 1,000-ft. levels have given new life to the company, and the erection of another heavy hoisting engine and new and powerful pumping machinery, has been commenced.

UTAH.—The shaft is sunk 70 ft. below the 400-ft. station. On the 400-ft. level the south drift has been extended 250 ft. south from the main east drift.

CHOLLAR-POTOSI.—There is no change of value to report of the ore producing sections of the mine. Daily yield 120 tons of ore, the assay value of which is \$30 per ton.

WOODVILLE.—Work in all parts of the mine is progressing as usual. The report of the trustees show the receipts of bullion for the past nine months to be \$30,219 05, the amount of assessments collected since July, 1873, \$133,000, making a total of receipts of \$163,219 05; total amount of expenditures during the same period, including the payment of \$36,533 of old indebtedness, \$160,041 69, which leaves a cash balance on hand of \$3,177 36.

NEVADA.—During the past two weeks the work in this mine has been concentrated upon sinking a winze to ascertain the value of a cross lead, met with in the face of the main south drift, 200 ft. from the main west drift or adit.

SILVER HILL.—The ore in the upraise, on the first level from the old St. Louis chimney, has been steadily improving for several days past, carrying a considerable quantity of rich brown sulphurets.

DAYTON.—The extraction of ore from the stopes on the second station level is prosecuted with usual vigor.

CALIFORNIA.—On the 1,400 and 1,500-ft. levels of the Consolidated Virginia shaft the drifts started north to connect with corresponding drifts from the Ophir mine are advancing steadily on the west side of the ore vein.

JUSTICE.—New hoisting machinery is being placed over the old Waller Defeat shaft, which will be completed in about a week, ready for ore extraction.

DARDANELLES.—This mine is to be brought into notice once more through practical development. During the past few days a new working shaft has been commenced at an eligible point on the company's ground, about 600 ft. southeast from the Overman shaft. The new shaft is already down 17 ft. to-day, and the work will be pushed ahead as rapidly as possible. At the depth of about 200 ft. this shaft will cut the ledge and pay ore.

IOWA.—The main west drift, 209 feet from the surface, is now being re-timbered for the purpose of resuming operations in that portion of the mine.

OVERMAN.—The main west drift on the 1,200-ft. level is still driven vigorously ahead.

MINT.—The bottom of the shaft last evening was in a heavy body of clay with every indication of a near approach to the hanging wall of the ledge.

FLORIDA.—The new shaft is down 75 ft. The company's new hoisting machinery is on the ground, and the boilers are being placed in position.

KNICKERBOCKER.—The face of the main west drift, on the 450-ft. level, still continues in quartz of a very promising character.

CALEDONIA.—Sinking the main shaft has been again resumed.

YELLOW JACKET.—Sinking the main incline is making the usual good progress.

BALTIMORE CONSOLIDATED.—Sinking the shaft is making about the usual progress, the flow of water at the bottom continuing steady and uninterrupted. The erection of the new machinery is steadily progressing.

NEW YORK CONSOLIDATED.—The new pumping machinery is all working with the utmost perfection.

LADY BRYAN.—Sinking the new shaft is making steady progress. The new machinery is working with the utmost perfection.

TYLER.—The ground in the face of the main east drift at the second station is working much softer and better, and the drift is progressing at the rate of 4 1/2 ft. per day.

MCMEANS.—The water blast is completed, and work in the face of the main tunnel has been resumed with good indications of some excellent ore developments.

SUTRO.—The main west tunnel is still being driven vigorously ahead, the rock in the face being quite hard, with a slight increase in the flow of water.

LEO.—The good ore streak in the face of the main drift still continues.

Reclamation of Swamp Lands.

At a recent meeting of the California Academy of Sciences, Mr. Chas. D. Gibbs, C.E., read a paper on the "reclamation of swamp lands." Mr. Gibbs is an old resident of California and has had great experience in the tle lands of the State. The various modes by which swamp and overflowed lands may best be reclaimed and brought into a state of cultivation will, of course, depend on many circumstances of which the nature of the soil is one of the chief considerations; also the rise and fall of the tides; together with slinices of sufficient capacity and properly placed to drain the land at least 18 inches below the general level of the surface. There are essential conditions on which alone the work of reclamation can be commenced.

This subject divides itself into so many branches, each so important, that we can only give a few condensed remarks from Mr. Gibbs' paper, in the hope of their being useful to those who are reclaiming; and to show some of the errors in the present manner of draining.

Drainage.

The first thing to be examined is the difference of level between the interior of the land to be drained and the bank of the slough or river on which the dike is to be constructed, in order to know the required depth of the ditch to enable it to keep the waters down to a level of 18 or 20 inches below the surface of the interior; for unless drainage is perfect the reclamation and cultivation are hopeless.

Frequently one or more small sloughs extend into the interior, which are of great advantage, forming a natural reservoir and drain for discharging the surplus water at every low tide.

The difference in the level of the land is frequently two or three feet.

Tide.

The next thing to be considered is the tides. In each lunar day of 24h. 50m. there are generally two high and two low tides, which are unequal in height and occur at unequal intervals.

In a series of observations on the tides, taken by me last summer on the coast, in San Mateo county, the result of one day shows that, commencing at low water large, it rose to 4.1 feet to high water small, then fell 1.7 to low water small, then rose again 4.3 feet to high water large; making a total rise of 6.7 feet, then fell 7.5 to low water large.

Now for some distance above the confluence of the Sacramento and San Joaquin rivers, the greatest rise and fall of the tide is six feet; high water small would average perhaps 3½ feet above low water large; and low water small about two feet above. A flood gate at a level with the lowest water would be most of the time under water and therefore afford but a very short run in the discharge of the water.

Flood Gates.

In the attempt to reclaim our tule lands, the flood gates have been a great source of trouble and expense, from the imperfect manner in which they are constructed and senced; in many places no calculation having been made for the amount of pressure they have to sustain; they frequently give way, and the sluice box is sometimes canted with one end four or five feet lower than the other. The reason is evident.

I speak now more particularly of the large sluices at the mouths of sloughs that are dammed they have generally been made of an open box 20 or 30 feet in length, 10 or 12 feet wide, and placed at the level of low tide. The levee being five or six feet high gives a gate, say 10 feet wide, 12 feet deep and three or four inches thick. This heavy gate, equal to about one-half a ton, is placed in the center of the box; consider now what a loss of power a small body of water, perhaps only one or two feet in depth, has, to raise the gate in discharging. But this is not the only error. We come now to the

Pressure of Water.

The weight of a cubic foot of fresh water is 62½ lbs. Water standing in an enclosure presses with equal force on the bottom and the sides of the junction, but the force on the sides will be in compound ratio of its depth. The pressure of a column of water a foot square, and six feet deep, equals 375 lbs., but the side pressure equals 1,312½ lbs.

Suppose we have an open sluice box 20 feet in length by ten feet wide with the gate in the center, 10x10 the square of the bottom outside of the gate=100 sq. feet x375 lbs.=37,500 lbs. or 18½ tons; and the pressure of each column 1,312½ lbs. x10 feet wide=13,125 lbs., or 6½ tons on the gate; width of water has no influence on side pressure.

Now, we generally find that these sluice boxes stand for some time until the water inside is reduced to the level of low tide, when, there being no resistance on the inside of the gate to counteract the enormous pressure outside, it gives way gradually day by day, until at last it is not surprising that it sinks outside and cants up inside; particularly when there is no sheet piling, only some inch or one and a half inch boards six or seven feet long put in the mud and tacked on at each end.

The same case occurs with the dams unless made sufficiently strong to stand the pressure, which against a dam 100 feet in length is at high tide about 65½ tons.

We have been referring to quiescent water; but in considering the forces of waves driven by wind, the pressure of flood tides, or the strength of a strong current against the embankment or flood gates, a large allowance must be made; it is scarcely possible, however, to reduce them to calculation, but we may safely add one fourth to the pressure. Great care should therefore be taken in selecting a site for a dam or flood-gate to avoid those spots that are exposed to any great currents or rush of tidal waters, particularly where a stream suddenly narrows, as the tide comes up very strong; and also to its exposure, with respect to the prevailing winds.

Where fresh water swamp lands are adjacent to high land, catchwater drains should be made to intercept the upland or external waters and conduct them off to a separate outlet.

Proper Level of Small Sluices.

The small sluices from the ditches or drains inside of the levee should be placed, if possible, sufficiently above the ordinary low water, to allow it to have five or six hours' run between tide and tide, beginning at half ebb and continuing to half flood tide; if placed at low water, the gate would be shut sooner by return of tide, although so long as weight of the water inside is greater, so long will it continue to run.

The best level therefore to afford the longest run, is probably between the mid-tide level and the lowest low water, or in fact as high as it will admit to drain the low land in the interior, 18 or 20 inches. The trunk or box sluice has

LEVEE PROPERLY CONSTRUCTED.

been used in the rice fields of South Carolina upwards of a hundred years, and has been found to answer better than any other. A good size for our use is about six feet wide by eighteen inches deep, with self-acting tide gates; if made of redwood and put in properly, they would last a long time, stand firmer, and are not liable to be thrown out of level by the pressure of water. They should be put down while you are making the embankment, as it is useful in keeping the land drained, and so facilitate the work. It is now more than twelve years since I furnished these plans to a gentleman on the San Joaquin, who found them to work well on his place.

The trunk dock connecting the outer end of the trunk with the river, should be wider than the sluice box, so as to allow the free egress of the water, and should also be deeper than low tide. The flood gates now being in place we can proceed to build the

Levee.

The materials of which the embankment is to be constructed will govern in a great measure the other requisites to be attended to in its formation. These materials differ essentially on the San Joaquin and Sacramento rivers in dif-

Levees Now Made.

ferent localities. On the San Joaquin we generally find a sod or turf of a peaty formation, which shrinks when dry about one-third; becomes very light and can either be burnt up or float away, while on the Sacramento it is composed of two kinds. In some places the turf has a sedimentary deposit of clay, which makes it firmer, heavier, and not so liable to burn. In other places the banks of the river are sandy, which is the most difficult material to manage, and the least to be depended on, and melts away like snar in water.

The first consideration is to determine the height of the levee to keep out the ordinary summer freshets, but it will not answer to have the levee of the same level, for in certain places it will be found necessary to raise it; for instance, I examined the water marks of the flood of '71 and '72 on trees about a mile apart on the same island where the bank was apparently the same height above ordinary tide, and found a difference of six to eight inches, which was caused by the confluence of two currents backing the water above.

Having determined the height that you wish to construct your levee add at least one-fifth for shrinkage and build it the proper height at once.

The distance from the ditch to the inner slope of the levee should be at least 12 or 15 feet, and from the outer margin to the river not less than 30 feet, and in some cases more; but it will depend a great deal on the formation of the bank, exposure to currents and winds.

The inner slope should be 1½ to 1; and the outer slope not less than three to one, or follow nature as far as possible, as the downward pressure of the water will assist to keep the levee in place, and the broader base will enable it to resist the inward pressure, which with a flood of five feet on the level will equal 45½ tons on every hundred feet in length, without allowing for the force of the current or wind. [The cuts on this page show the proper method of constructing levees and the improper

method on which many are making them now.—ENS. PRESS.]

Whilst the levee is yet wet, sow mesquit or Bermuda grass seeds on it, either of which will form a good sod to protect and bind the levee together and prevent it from cracking; also would form a good pasture for a few sheep or Angora goats.

Care should be exercised in running ditches into the interior; first the ground should be examined that you do not cut through float land, second to ascertain the level; for I have known a contract let to Chinamen to dig a ditch three feet deep, and when completed the water ran back and flooded the low land. Unless your levees and flood gates are properly constructed it is only a waste of money to attempt reclamation.

The Murchie Mines.

The Nevada Transcript says: We yesterday visited the mines owned by the Murchies, which are situated about a mile and a half east of this city on the Red Dog road. They have a hydraulic mine and two quartz mines. One of the latter is called the Lone Star, and the other the Independent. The Lone Star was struck a few years ago, while running a drain tunnel to the hydraulic mine. They have taken rock since from the ledge through this tunnel, which has never paid less, on an average, than \$21 per ton. Another tunnel was commenced

some time ago further down the side of the hill, which taps the ledge about 375 feet deeper than the first one. The ledge was reached about ten days ago, and we gave a short notice at the time about the rich rock found in it. There are now between 75 and 100 tons of rock taken out at this point, and it is difficult to find a piece that does not show rich in free gold. The gold is visible among the sulphurets with which the rock is heavily charged. We do not believe the same amount of rock can be found anywhere which will show so much gold as can be seen in this with the naked eye. It does not seem to be specimen rock, but a general distribution of gold through all the quartz. The ledge is two feet thick, and is very easily worked and taken out.

The Independent is about four hundred yards or more from the Lone Star. This mine is worked by means of a shaft, and the hoisting is done by steam power. The ledge averages from twenty inches to two feet thick. The shaft is down over 300 feet, and the ore has paid as high as \$75 and \$80; it averages about \$26 to the ton. The mine improves in looks as a greater depth is attained. The rock from both ledges is crushed at a mill belonging to the company, situated on Deer creek just below the mines. It is run most of the time by water power. An engine has been put in, however, and hereafter when water gets low, the mill will be run by it. The batteries have eight stamps, and the gold saving apparatus consists of copper sluices, grinders, rockers, etc.

The hydraulic mine has quartz boulders scattered all through the gravel; these have been saved and crushed also at the mill. They have produced gold enough to pay the expenses of running the mine. The lead in this gravel claim is very rich, and is but just barely opened. The Murchie family, consisting of five brothers and their father, own and work all the mines. Being practical miners, they make everything count. They have been doing a large amount of dead work in order to open out their mines, which are as yet comparatively undeveloped; but regular dividends have been received all through the time. Everything now is in good working order. The property, taken together, is one of the most valuable in the county. It has been opened up and developed by hard work, and its owners have the hearty wish of all for abundant returns for their labor.

IMPROVED DRAFT EQUALIZER.—The object of a new invention is to produce an equalizing attachment for three horses, to be applied to reapers and other vehicles, by which a greater effect is obtained, and the side draft regulated, as required. The weight of the tongue on the neck of the horses may also be adjusted. The invention consists of a curved bar which is attached to the tongue, and carries the rear extending bar, with regulating rod, which connects with and is adjustable on a cross bar of the bounds. Both bars together support the equalizing bar, and allow the adjustment of the same into any required position.

OATMEAL.—In answer to a correspondent, who asks whether oatmeal is heating to the blood, the editor of the Herald of Health says: Nearly all foods are to a certain extent heating; if they were not they would be worthless. Now from this standpoint oatmeal is a little more than half as heating as butter. As regards the fattening properties of oatmeal, brown bread, etc., if you are already to fat use more acid fruit as a part of your diet, and work harder. Butter and sugar are more fattening than fruit; avoid these to a great extent, also much milk and cream.

Pioche Mines.

From the local mining review of the Pioche Record, of May 31st, we take the following: Prospecting in the lower depths of our principal mines is being pushed as rapidly as circumstances permit, but thus far the explorations have not revealed any new features. During the past few days an effort has been made to resume sinking the main shaft of the Raymond & Ely, but the water came in too rapidly to permit of further operations with present appliances. This attempt and its lack of success show conclusively that until adequate pumping machinery is erected, nothing more can be learned of the nature of the lead at a greater depth than the 1,200-foot level. This observation will apply as well to the Meadow Valley, for the water at the bottom of No. 3 shaft will no doubt be equally plentiful as in the Raymond & Ely. We regret this, as we indulged in some faint hopes that as the Raymond & Ely was a perpendicular shaft, that with its powerful hoisting machinery, barrels or tanks might be raised with sufficient rapidity to keep this bottom clear. This expectation the experiment of last week proved to be fallacious, so further sinking is out of the question until the requisite means for raising the water are provided.

The bullion yield for the week, considering all things, is encouraging, amounting to \$78,989.89. If Pioche in its dullest time produces the precious metal at this rate, what may we not hope for when the season of its active prosperity returns, as we believe it shortly will?

Washington and Creola.

Since our last report about 25 feet have been added to the depth of the Mazappa shaft. The drift from the lower level running eastward to strike the shaft has also made good progress. The work on the west winze has been stopped, the air becoming foul. The middle winze is being sunk, and a connection will be made during the present week that will have the effect of affording better ventilation. The returns from the last crushing at the Floral mill were quite favorable, and so soon as the mill completes the necessary repairs, it will recommence on rock from this mine; that is, from the stock on hand, for at present no ore is being raised. A shipment of about \$6,000 was made during the week.

Raymond and Ely.

An attempt has been made during the last week to continue sinking the working shaft, but the flow of water was soon found to be too great to permit its removal without the use of pumps; so, therefore, the men were withdrawn. On the 1,200-foot level the drifts east and west have been started, following the ledge. The appearance of the latter presents little or no difference from the point where it was intersected by the crosscut. The remainder of the mine calls for but little remark. From the slopes of the upper levels ore is being extracted and shipped to the mills. The yield from the latter for the week is a little over \$20,000.

Meadow Valley.

No. 3 shaft.—The crosscut at the 1,200-foot level is now 59 feet in length, and must be in the immediate vicinity of the vein. The west drift on the 1,100-foot level is in 291 feet, and the east 191 feet. The vein on the western side appears very much broken, on the east presents but little change. The eastern drift on the ninth level is now 817 feet in length. The face does not offer any different appearance from last report.

No. 5 or Summit Shaft.—This is now 1,061 feet deep, and sinkings progressing as quickly as possible. The drift to connect with the ninth level of No. 3 is in 25 feet. About the usual quantity of ore is being raised from the mine and is yielding about the same results. At the mill operations are progressing as usual, without any occurrence out of the ordinary routine.

Newark.

The contractor is at work on the new shaft, formerly the Amador, and about 12 feet has been made during the past week. In the mine the winzes are being sunk from the lowest or 700-ft. level; is 200 feet in depth. From the fourth level upwards, stoping is going on in various parts of the mine, and about ten tons of ore are being raised daily. The mill is being kept actively employed on the company's ore and custom work, only having been idle one day since its possession was acquired, and that was necessary in order to effect some repairs. Bullion to the amount of \$16,000 was shipped during the week just elapsed.

American Flag.

The American Flag mine still presents the favorable appearance we have noticed of late. The shaft is being sunk as expeditiously as possible, and is now 85 feet below the ninth station. Above that level a number of men are at work stoping, and sufficient ore is being extracted to keep the mill employed. The shipment of bullion for the past week is about \$6,000.

In the Pioche, Portland, Havana, Chief of the Hill and other mines at work there is little or no change to report. Matters within these undertakings are proceeding as usual, and afford no room for additional comment.

ANTIMONY BLUE.—Kraus obtains this color by boiling tartar emetic with yellow prussiate of potash, and adding hydrochloric acid. The antimony does not enter into the composition of this color, but merely facilitates its formation.

USEFUL INFORMATION.

Waterproof Structures.

While one useful set of inventors is constantly striving to the utmost to furnish an efficient protection for buildings against the ravages of fire, another is endeavoring to counteract the equally damaging, though slower action of water. It is too evident to need proof that rain falling from above, and moisture absorbed from below, constitute an important element in that deterioration of structures which is continually going on. In all probability the damage done by weather to such buildings as the Houses of Parliament is mainly due to the action of aqueous vapor and rain, bearing in solution some of the gases which are invariably generated in large towns. Sulphurous acids from the combustion of coal, carbonic acid from the same source, and from the respiration of millions of inhabitants, and, possibly, hydrochloric acid from such operations as those of the Lambeth potteries, all tend to give the moisture always present in the atmosphere the power of attacking the carbonates of the alkaline earths which are usually employed for building purposes. The surface disintegration thus caused is the first stage in their deterioration, producing a roughness, which leads to a crumbling away of the material in successive layers.

Besides this chemical action of acid vapors there is a mechanical agency at work, similar to that which produces the disintegration of rock surfaces resulting in the production of soils. This is the absorption of water, and its subsequent expansion by frost, causing the fracture of the material by which it is absorbed. Manifestly the most porous stones are the greatest sufferers by this agency, though nearly all building materials are affected by it; for, as is well-known, both brick and stone are porous, some varieties extremely so. This porosity is the cause, not only of "weathering" on external surfaces, but of that slow creeping up of moisture into walls, resulting in the incurable dampness of dwelling-houses. The introduction of slate in the courses of brickwork is a preventive sadly too seldom employed.

As might be expected, many attempts have been made to remedy the evil alluded to. These attempts are of two kinds—chemical and mechanical. The most noteworthy of the chemical methods is that depending on the use of alkaline silicates with calcareous and magnesian stones. Here an interchange of acids and bases occurs, an insoluble silicate of lime or magnesia being incrusting on the stone, and an alkaline carbonate, and sometimes sulphate crystallizing out. The chief objections alleged against this system are the unsightliness of the efflorescence, and the necessity of removing it, as well as the length of time necessary to effect the reaction. Still, there is little reason why a chemical method of this kind should be a failure, and if that important element in all chemical changes, time, is only at command, a chemical protection against decay would seem to be efficient as any.—*Iron.*

PETROLEUM FOR FUEL.—The Titusville, (Penn.) *Herald* says: With the present low prices the question of employing petroleum as fuel is again agitated. The latest intelligence upon the subject comes from Canada, where a man named Relighine has been trying an experiment on a locomotive belonging to the Canada Southern railway, with an average consumption of four gallons per mile. The engine steamed quite freely and made good time with a train of 30 cars. This would be about a barrel for over 10 miles. The most simple contrivance for burning petroleum is either by means of a jet of steam or compressed air passed at right angles over the orifice of a pipe in such a manner that the oil will be sucked and thrown into the furnace in the form of a fine spray, where, if properly adjusted, it will undergo perfect combustion. The cost of the apparatus is trifling. The whole point, it seems to us, turns upon cheapness, and as the market might go up rapidly with any marked increase of demand, there seems to be an indisposition to try the experiment. There can be little doubt that oil will be found in many parts of the country where at present it is not thought of, in which case a new and unlimited market for its utilization as fuel would naturally follow.

CLEANING GLASSWARE.—Dr. I. Walz, who has devoted considerable attention to the uses and properties of potassium permanganate, has devised the following neat and effective method of cleaning glassware: The vessel to be cleaned is filled, or, if large, rinsed, with a moderately dilute solution of potassium permanganate, the contact of liquid being prolonged till a film of hydrated manganic oxide has been deposited; the solution is then poured away, and the glass vessel rinsed with some strong hydrochloric acid. Chlorine is then formed, but not enough to cause inconvenience; and, acting in the nascent state on the organic matters, it speedily converts them into substitution products, which are absolute in the slight excess of acid or water.

DETECTION OF CURARINE.—F. A. Fluckiger finds that curarine may readily be distinguished from strychnine by the fact that its chromate is amorphous, that of strychnine being easily obtained well crystallized. Further, air-dried chromate of curarine dissolves in concentrated sulphuric acid with a pure and very intense blue color, while the chromate of strychnine gives a violet.

Inventors' Mistakes.

Inventors are too liable to think that upon the granting of their patents success is certain, which it would be if they would display as much business tact as they have done inventive ability. Upon the granting of a patent the inventor thinks his "future made," and thereupon sits down, waiting for the dollars to come without any effort on his part to induce a flow of coin into his treasury. After a season of such inactivity, with poverty finally staring him in the face, he parts with his patent for a small sum to a shrewd business man, who places the matter before the public in a business-like way, advertises it in mediums through which it reaches the attention of all in need of that particular invention, eventually creating for it a large demand, and bringing a correspondingly large revenue to the advertiser.

The day has passed when people have any desirable thing to sell may expect to reap success by waiting for the public to seek them out. At the present day, every important branch of manufacture has its own special organ; if an inventor has anything to sell which is worth buying, the attention of purchasers is expected to be called to the fact through such publications, as well as through the mailing of circulars, etc. A large proportion of the patents granted are for inventions of real merit, and of value to the public, and inventors and the public are alike sufferers for this very want of business tact on the part of inventors, who should, immediately upon the issuing of the patent, have it properly engraved and published in such journals as reach readers who require the use of such particular inventions. "Masterly inactivity" has ruined many an inventor who might otherwise have been to-day in the possession of a fortune.—*Newark Manufacturer.*

GRAINING MIXTURE IN DISTEMPER.—Take equal part of yellow ochre, burnt sienna, and raw umber, and mix with ale, beer, or vinegar and sugar. Then with a bristle brush spread on the mixture—or as termed by grainers, "rub in" as smooth and evenly as possible; or, it may be applied with a sponge, going over only a small portion or panel at a time, for the distemper colors dry quickly. Then with a graining comb made of leather or gutta percha, make the coarse grain by drawing the comb over the surface in a zigzag manner; then with a finer steel graining comb draw over the whole panel again in the same direction; then with a piece of soft muslin folded over the thumb of the right hand, make the heavy grain or figures by wiping out the graining mixture; this done lightly pass the fine comb over the work again, or with a thin flat bristle brush, lightly brush over the surface to blend or soften the heavy lines. Proceed in this manner over all the parts to be grained, and by imitating the real wood—as near as possible, a very fair piece of work will result. A professional grainer would overgrain, and mottle, and stain, and glaze, etc., but as a description of these processes would tend to embarrass the amateur, we do not deem it judicious to extend upon these extras.—*Am. Homestead.*

ADULTERATION OF ALBUMEN.—Albumen is frequently sophisticated with gum, dextrine, farina, etc. To ascertain this, about thirty grammes of the albumen are dissolved in lukewarm water. After some time the mass is stirred. If the liquid contains many white clots the quality is low, that is a notable amount of the albumen has been coagulated by evaporation at a too high temperature. The solution is mixed with acetic acid, and alcohol is added to the clear acid liquid after decantation. If gum is present a precipitate will appear. If it contains amylaceous matters these can be recognized by the addition of iodide of potassium. Albumen often contains sugar, which is detected by means of Fehling's test-liquor.—*Iron.*

METHOD OF RENDERING PHOTOGRAPHS SOFT AND BRILLIANT.—Engelmann accomplishes this object by placing in front of the sensitized plate, during half of the time of exposure, a plate of ground glass, rendered more transparent by rubbing with sweet oil. The ground glass is then removed, and the plate exposed as usual, so that two negatives are produced, one overlying the other, on the same collodion film. The development and printing are conducted as usual, but a rather shorter exposure is advised. With these negatives both positive and negative retouching are said to be unnecessary.

TANNING.—A recently patented process consists mainly in forcing, by the aid of pressure or exhaustion, tanning or other liquids through the pores of the skin or hide, which is laid on a suitable filtering or porous surface on the bottom of a vessel, into which the liquor is then poured. The skin or hide is removed from time to time and immersed in a stronger liquor, after which it is again laid, the other side up, on the filtering surface. To remove lime from the skins, they are thus impregnated with a weak saccharine solution and washed in water.

AROMATIC MIXTURE.—A formula from the collection recently published, for use in the Philadelphia Hospital, affords a pleasant vehicle for administering nauseous remedies. It consists of coriander and angelica seeds in spirits of wine, water, glycerine and syrup.

THE BREATH.—A disagreeable breath can be avoided by keeping the mouth clean, the teeth filled and sound, the stomach healthy, the skin active, and by always breathing pure air.

GOOD HEALTH.

The Future of Hygiene.

Dr. Jarvis, in the *Sanitarian*, inquires: Where shall sanitary science be taught? And to whom shall it be taught? I will answer this question by and by. In the meantime, let me ask: *Who need sanitary instruction?* In my opinion, the people need it—and the medical profession need it. Let the elements of hygiene be taught in every common school, in every academy, in every private school, and in every college in the country. The bodies of our youth need the saving grace of cleanliness. And when they grow up they will teach their children the simple and health-saving rules of hygiene. But where shall we begin to dissipate ignorance? Why, of course, begin with the medical profession, and begin with undergraduates.

It was a damaging thing, when one of the officers of health of New York city gravely informed Judge Whiting that "highjinnicks" meant "a bad smell arising from dirty water,"—damaging both to politics and medicine, but most damaging to the people, whose most important interests were in the hands of ignorant keepers.

But what shall I say of medical schools and hygiene? If medical schools taught hygiene *per se*, and insisted upon their graduates being "posted" in the principles of sanitary science, officers of health would at least have the merit of being sanitarians.

What hope is there for hygiene in this country? Will it succeed? Can it be planted among the people? And will it grow and flourish? In my opinion, hygiene has a grand future in this country; I will tell you why I think so. The American youth—and especially those who come here to study medicine—have a practical turn of mind; they do not believe much in theories—they believe in the useful first, and after that, the beautiful. It is an acknowledged fact, that our medical men are among the best practitioners in the world; they have more science on the other side of the ocean, but our students are always wanting to know what will cure their patients, and they generally find out, too. Now, I hold that this practical turn of mind is the best kind of soil for the cultivation of sanitary science. Let the seed be planted there—it will take root and grow, and it will be perennial; the seed will be scattered over the length and breadth of the land, and the harvest will abound more and more; the calamities that befall Memphis and Shreveport will not occur again; the beauty and healthfulness of our rivers will not be marred by dead animals, by the refuse of factories, and by sewage; there will be more to live for, and life will be more desirable; there will be less sickness and less need of medicine. Hygiene will be invited to come to our banquets; she will be a perennial guest in our homes; she will be the presiding genius of our hospitals; she will be sculptured in marble and wrought in bronze in our public parks; and she will be raised high above medicine, and enthroned in the Capitol of the nation with Liberty.

PETTENKOFFER SAYS, in the *Herald of Health*: The difference of temperature between a place sheltered from the rays of the sun and a neighboring one exposed to them, produces a motion, a current, because bodies of air of unequal temperature are also of unequal weight. They are not in equilibrium, and seek to re-establish it by motion. Any one may easily convince himself thereof who, on a hot day with calm air, walks alternately over places exposed to the sun and sheltered from it. As soon as he comes into the shade of a cloud, a house or a tree, he feels at once a soft wind rising. The shade not only protects us against the direct solar rays, but it increases also the ventilation of the shady place. The fan acts on the same principle. The panksh in the bungalow, by increasing conduction and evaporation, keeps the blood of the European at its normal temperature of 99°². When the temperature of the air rises to 140°, when the walls of the bungalow are no longer cool enough to provoke radiation from the heated human body, man is reduced to cooling by evaporation. It greatly depends upon the state of dryness of the air how far he succeeds. The drier the hot air is, the better is it able to withdraw water from the skin, from the respiratory organs, from the wetted floors, and consequently the more heat from the human body. The moister it is the less it is able to act thus. In order to give you an idea of the quantitative differences in play, we will consider the losses of heat by respiration as they take place at different temperatures and different conditions of moisture of the air we draw in. In twenty-four hours the quantity of this air is on an average 2,000 gallons. It has been calculated that by the process of respiration a person loses 1,172 caloric units when the air is at 32° and quite dry, 1,116 when it is half saturated by water, 1,060 when it is completely so. The difference between the two extremes is only a small percentage of the whole loss. But when the temperature is 86° the above numbers would be respectively 1,096, 760, and 420.

Dr. BEARN, of New York, says the golden decade in the age of the mind, is between thirty and forty, the silver, between forty and fifty, the brazen, between twenty and thirty, and the iron, between fifty and sixty years. It is impossible, of course, to fix definite limits, which would apply equally to all.

Checking Coughing, Sneezing, Etc.

There are many facts which show that morbid phenomena of respiration can also be stopped by influence of arrest. Coughing, for instance, can be stopped by pressing on the nerves on the lip in the neighborhood of the nose. A pressure there may prevent a cough when it is beginning. Sneezing may be stopped by the same mechanism. Pressing also in the neighborhood of the ear, right in front of the ear, may stop coughing. It is also true of hicough, but much less so than for sneezing or coughing. Pressing very hard on the top of the mouth inside is also a means of stopping coughing, and I may say that the will has immense power there. There was a French surgeon who used to say, whenever he entered the wards of his hospital, "The first patient who coughs here will be deprived of food to-day." It was exceedingly rare that a patient coughed then.

There are many other affections associated with breathing which can be stopped by the same mechanism that stops the heart's action. In spasms of the glottis, which is a terrible thing in children, as you well know, as it sometimes causes death, and also in whooping-cough, it is possible to afford relief by throwing cold water on the face, or by tickling the soles of the feet, which produces laughter, and at the same time goes to the gray matter that is producing the spasms and arrests it almost at once. We cannot always prevent cough by our will; but in many instances these things are possible, and if you remember that in bronchitis and pneumonia, or any other acute affection of the lungs, hacking or coughing greatly increases the trouble at times, you can easily see how important it is for the patient to try to avoid coughing as best he can.—*Ex.*

Lead Poisoning.

The *Annales de la Société de Médecine de Grande, Belgium*, speaking of lead poisoning caused by the use of a hair preparation, relates the case of M. R. W., aged fifty-five, who was suffering from muscular rheumatism, affecting chiefly the deltoid and other muscles of the shoulder; the patient had also lost the use of both arms. Dr. Crocker, the attending physician, had the painful parts wrapped up in cotton wadding, and prescribed lime juice and narcotics. A great improvement was rapidly felt, but it only lasted for a short time, for a month afterwards the patient's fingers were struck with paralysis. No blue tinge could be seen on his gums, though he had suffered with severe colics at various times. The water used for drinking purposes was obtained from a brick well and kept in wooden pails; the culinary utensils offered nothing worthy of notice.

At last, after long researches, Dr. Crocker discovered that for the 15 years preceding, his patient had been in the habit of using, for blacking his hair, a certain liquid that he prepared himself by adding to a pint of water two teaspoonfuls of sugar of lead and three teaspoonfuls of sulphur. This he used to apply to his hair at least once a week. The physician stopped entirely the use of the mixture, and under the influence of electricity and the use of iodide of potassium the colics disappeared and the patient recovered entirely.

AN INCESSANT WANT.—One of the incessant wants of man is air. We want air mainly to nourish us and to keep us cool. The quantity of air inhaled and exhaled by an adult in 24 hours amounts on an average to about 300 cubic feet, or 2,000 gallons. What we take in and give out during 24 hours in the shape of solid and liquid food, occupies on an average the space of five and a half pints, which is equal to one three-hundredth of the volume of the air passing through our lungs. It will astonish you to hear, perhaps for the first time, that this amounts to 730,000 gallons in one year, and to be reminded of that continuous work which goes on day and night—a never ceasing bellows-blowing, by which the organ of our life is kept in play. Of course the quantity of air flowing round the surface of the human body is greater than that. Do not object that air is something so light that it need not be taken into account. It has some weight; water, certainly, is 770 times heavier, but our daily 2,000 gallons have for all that a weight of 25 pounds avoirdupois.

NOXIOUS GASES IN WELLS.—Lives are frequently lost by noxious gases in wells. This may be prevented by the adoption of the following very simple means: Take some pieces of carpet, or common sacks, and make them up into a loose bundle, nearly as large as the area of the well. Enclose in it a brick to give weight, and attach to the bundle a rope of sufficient length to reach the bottom of the well. Throw this bundle down the well, and haul it up again as quickly as possible. Repeat this operation rapidly for ten minutes, and the atmosphere of the well will become quite innocuous, as may be proved by letting down a lighted candle. The bundle, as is easily understood, carries before it a quantity of fresh air from the surface, and this, of course, displaces the foul and dangerous air from the bottom.

BATHING.—Delicate people may bathe daily if they do it in a warm room, in tepid water, and use much friction and little water. They ought to bathe at least three times a week. The morning is a good time, and so is the middle of the forenoon.

TABLE OF CONTENTS.

GENERAL EDITORIALS.—Swingle & Huntington's Improved Breach-Loading Fire Arm; Public Documents for Miners, 369. The Emma Mine; The White Pine Tunnel; Economy in Using Quicksilver; A New Mining Bill, 376. The Quicksilver Monopoly; Geology of the Emma Mine; The Negley Amendment, 377. The Partnership Publication Law; General News; The Vanishing Forests; Patente and London, 380.

ILLUSTRATIONS.—Swingle & Huntington's Repeating Rifle; Swingle & Huntington's Breach-Loading Shot-Gun, 389. Levee Properly Constructed; Levee Now Made, 374. Geology of the Emma Mine, 377.

CORRESPONDENCE.—Mining in Plumas and Sierra Counties, No. 370.
SCIENTIFIC PROGRESS.—The Time Taken in Nerve Telegraphy; Fracture of Metals; Mineral Waters; Precipitation in Fresh and in Sea Water; The Centennial of Chemistry; Rendering Wood Uninflammable, 371.

MECHANICAL PROGRESS.—An American Coal-Cutter; The Fireless Locomotive; Scotch Bricks; Copper Tubes; Pumps for Locomotives; Mowing and Reaping Machines; Metallic Floors; Improved Bale Tie or Buckle, 371.

MINING STOCK MARKET.—Table of Daily Sales and Prices and Comparative Prices for the Week; Notices of Assessments; Meetings and Dividends; Review of Stock Market for the Week, 372.

MINING SUMMARY from various counties in California and Nevada, 372-3.

USEFUL INFORMATION.—Waterproof Structures; Petroleum for Fuel; Cleaning Glassware; Detection of Curatins; Inventors' Mistakes; Grain- ing Mixture in Distemper; Adulteration of Albumen; Method of Rendering Phot. Graphs Soft and Brilliant; Tanning; Aromatic Mixture, 375.

GOOD HEALTH.—The Future of Hygiene; Check- ing Coughs, Sneezing, Etc.; Lead Poisoning; An Incessant Want; Noxious Gases in Wells; Bathing, 375.

MISCELLANEOUS.—Quicksilver in San Luis Obispo County; The Sticksen Mines; The Summer Mine; Mines of Nova Scotia; Life-Boat Stations; Jersey Mining District; Alpine Mining; A Steam Quaker; The Woodville Mine, 370. Reclamation of Swamp Land; The Murchie Mines; Improved Draft Equalizer; Ploche Mines; Anthony Blue, 374. Silver Mines; New Machinery at the Consolidated Virginia; The Optic Nerve; The Mulline & Ryan Gravel. Olam—A Lucky Purchase; Charcoal and Bullion at Eureka; Mining Interests at Eureka; A Eureka New Mill; Let Us Have Figures; Coloma; The Blake Hoax; Recipe for Gine; Improved Modes for Preparing Medicine; The Mineral Resources of Texas; Placer, 378. Mining Prospects in Montana; Eureka Consolidated Strike, 379.

CAZIN'S JIG.—We gave, in a recent issue of the Press, a description of Cazin's Automatic Continuous One-plunger Jig. A description of the machine is also given in the last Annual Report of R. W. Raymond, U. S. Mining Commissioner. Mr. Cazin writes us that both notices necessitate supplementary information on his part, to this effect: For some time past he has constructed the jig with four or five sieves, and to end, thus allowing a reserve sieve for catching the mixtures.

The enterprise originated by S. N. Stranahan and others, about a year since, to tunnel through from American to Bear river, Placer county, and thereby open up a section of mining country to development which would otherwise be impossible, has been incorporated under the name of the Bear River Tunnel, Flaming and Mining Company. Capital stock, \$10,000,000.

NEW PLACERS.—Thirty miles below the Japa placer mines, in Lower California, rich mines are said to have been discovered recently, and miners are flocking to the new diggings. It will not be long before they flock back again, with complaints about scarcity of water. That part of the country has paid as little to Americans as Utah mines have to Englishmen.

The People's Northern California Stage Company has been incorporated, for the purpose of running stages in Shasta, Trinity and Siskiyou counties, and elsewhere. This company has secured the mail contract from Shasta to Yreka, on the Trinity Center and Scott Valley route, and will put on a daily line of stages, commencing 1st of July.

SALE.—H. M. Newhall & Co. sold at auction, this week, the entire mill property of the Rising Star Silver Mining Company, located at Flint, Owyhee county, Idaho Territory. M. J. McDonald was the purchaser, at \$8,100; the property cost \$68,000.

The Emma Mine.

The meeting of the Emma Mining Company was held in London, on the 15th ult. A very extended account appears in several of the English papers, from which we should judge that the meeting was rather a stormy one. The report of the directors and managers, of which we gave an abstract last week, was read and adopted, and the meeting adjourned to June 19th.

The report, as we stated before, was a very discouraging one, etating that they must depend entirely on new discoveries for future ore supplies from the mine. Very naturally the character of the report dissatisfied many of the shareholders, who would much rather have had a favorable report, so that they could sell their stock at as little loss as possible. This is one reason, probably, why the meeting was such a stormy one. We have not the space even to give a simple condensation of the report of the meeting, or comment on some of the statements made, but content ourselves with a few remarks concerning the management of the mine. In looking over some of the Salt Lake papers, it appears to a casual observer, as if they and their correspondents were more eager to get up an excitement over strikes in the mine, than to stick to actual facts. They pitch into Mr. Attwood for exercising unusual caution in keeping everybody out of the mine, and then give credence to the reports of correspondents as to the immense reserves of ore in sight and rumors of rich strikes. The managers at the mine send statements to the directors, contradicting the rumors of rich strikes, and wish the mine to stand on whatever merits it possesses; correspondents concealing their names, who are unable to get into the mine to examine it, send articles to the news papers describing new strikes and rich bodies of ore; and who are to be believed? Surely it seems to us that the gentlemen in charge of the mine ought to be believed before those disinterested (?) parties who make statements not borne out by future explorations, and who fear to sign their real names to their effusions. Managers, known by name, have reputations at stake, while unknown correspondents have none.

People write to Salt Lake papers and purpose to misrepresent the facts. One correspondent half quotes Mr. Murray's report, and then wants to know how it was that if the mine was exhausted they could pay above expenses \$131,000. If he had foinised Mr. Murray's report in the quotation, he would have known where the ore came from, for Mr. Murray said that all the ore left in the mine "was the leavings of the old workings, scrapings of the walls, ore that may have been entombed by the cave, old fillings and second-class ore on the dump." That is precisely where the ore came from that produced the bullion this year; but by suppressing a few lines of Mr. Murray's report, the whole facts were misconstrued.

Mr. Attwood is also misrepresented by plenty of people, most of whom, however, have stoek to sell, no doubt. The Utah Mining Gazette quotes a statement by Mr. MacDougal, made at the meeting, saying that Mr. Attwood had been asked who the manager of the Illinois tunnel was, and that he did not know, whereupon some scornful remarks were made concerning him. Now, Mr. Attwood was not asked any such question. He was asked if Mr. Park owned in the tunnel, and replied that he was under the impression that he did, but had no proofs. Perhaps Mr. Park had told Mr. MacDougal or some of the Salt Lake correspondents, but he had not told Mr. Attwood, or he would have said so.

Now we protest against the wholesale denunciation of the managers and directors as schemers until it shall have been proved that they are such. And as the Superintendent of the mine recently said, is it perfectly fair to assume that every expert who visits the mine and reports favorably on it must necessarily be an honest man and every person connected with the management a knave?

Is it not more probable that the gentlemen connected with the mine will make more reliable statements than parties having stock to sell, who write anonymously to the papers? Surely there has been enough misrepresentation about this and other Utah mines, to injure the mining interests there, without letting it go any farther. If there is plenty of ore in the mine and Mr. Attwood says there is not, any reliable expert who examines will expose the falsehood and Mr. Attwood's reputation will be gone. But unfortunately for these very disinterested (?) parties (owning stock), three reliable experts fully corroborate Mr. Attwood's views. But we notice that the reports of Clarence King, E. S. Blackwell and Andrew Murray are conveniently slurred over or ignored entirely by the people who so industriously circulate stories of rich strikes in the Emma.

The American name has been sufficiently disgraced already by the transactions connected with this mine, and for the sake of the future of our mining interests, it is to be hoped that our brethren of the press in Utah will be careful not to swallow everything told them by correspondents who are interested in misrepresenting this mine. If a few of these "experts" and would-be managers should get hold of the property, there would be immediately a rich strike and at the same time plenty of stock for sale. It is for the interest of Utah that misrepresentations should cease and that the real state of this mine should be made public.

The White Pine Tunnel.

The Senate Committee on Mines and Mining have reported with amendments a bill granting certain rights to aid in the construction of the tunnel under White Pine mountain. It grants 2,000 feet on the east side on all ledges discovered and not heretofore claimed, two sections of land at the mouth of the tunnel, and requires the expenditure of \$250,000, within two years from the passage of the act, and the same sum each year thereafter, until at least four miles shall be completed.

It is understood that Sargent opposed the bill in committee, on the ground that ample facilities are granted by the general mining laws, and that this bill is only an egg to be hatched into another scheme.

In view of the fact that the committee has reported favorably on this project, it is to be hoped that all the mining companies anywhere within a radius of a few miles of the proposed tunnel, will immediately interpose such objections as they may think proper, and see that these objections are laid before Congress. It will be much better to do this now than to wait a few years, until three or four hundred thousand dollars are expended on the tunnel, and then begin to hunt up reasons why the tunnel is objectionable. Moreover, it would save the projectors of the tunnel a great deal of trouble, time and money, if this suggestion should be adopted. The Sutor tunnel business has caused such a waste of ink and paper, such a waste of words, and so much commotion generally, among not only the common miners in Nevada, but the members of Congress in Washington, that the people do not want to see a repetition of the subject. If the White Pine tunnel is to be of any service, the people in that part of the country should encourage it; if it will only benefit a few, let the others throw cold water on it at once and try to drown it out, but not wait till it is half completed before taking steps to block the way. At all events, do one thing or the other immediately, do not encourage it willingly at first and then vituperate the scheme and the promoters when you change your minds. Above all things, if there are to be contracts, see that they are drawn properly, and stick to them when signed, or do not sign at all.

Economy in Using Quicksilver.

In corroboration of the views of certain of our correspondents in regard to "economy in the use of quicksilver," "C. H. A." informs us of the fact that on Mack's mill, at Benton, Mono county, Cal., only enough quicksilver is used in the harrelle to form a hard amalgam, which adheres to the copper balls, the process used being that invented by Mr. Aaron. In this case the economy consists only in the smaller working stock of quicksilver required, as the final loss was, and perhaps still is, in that mill large. This is ascribed by some men in this city, to the fact that so little is used.

But having watched the process for five years, our correspondent is in a position to assert that the loss at Mack's mill is not due to using too small a quantity of quicksilver, and the remedy, though not apparently understood in that mill, is very simple, and will be fully explained in the long promised series of articles on our correspondent's method of amalgamation, which are now in course of publication.

The practice of working a "dry" amalgam was introduced by Mr. A. B. Williams, with the express purpose of avoiding a loss of quicksilver, and our "C. H. A." has experimented on it, and carried the principle still further, as will shortly appear; but it seems to him, that except for the fact that a smaller working stock is required, there is no advantage in using so little. The real saving of quicksilver in the process lies in another direction, though the fact remains, that the use of amalgamated surfaces of copper, or other suitable metal, will effect a certain economy.

ANOTHER BENEFACTOR.—The will of J. Edgar Thompson, the well known railroad man, who died in Philadelphia recently, provides that the Trustees are to appropriate the remainder of the net income of the estate, after payment of specified sums for so much as may judiciously be applied thereto, to the education and maintenance of female orphans of railway employees, whose fathers have been killed while in the discharge of their duties. Preference is to be given—first, to orphans of employees engaged upon the Pennsylvania railroad; second, to those of the Georgia railroad, between Augusta and Atlanta, Ga.; third, to those lines controlled by the Pennsylvania railroad, by lease or otherwise; fourth, to those of the employees of any railroad company of the United States of America. The estate is valued at about two million dollars.

BIG DITCH.—A correspondent writes from Baker county, Oregon, as follows: "The El Dorado ditch is now running water to some of the richest mining ground in the world. This ditch is 100 miles long, and carries enough water to supply thousands of men. The mines are rich, the climate healthy, living cheap, and cost of travel here reasonable."

The Lightning creek (Cariboo) claims have taken out in less than a year past, 26,504 ounces of gold, worth in Victoria \$17.50 per ounce, or an aggregate of \$570,445.90 in value.

A New Mining Bill.

A bill has been introduced in Congress, which requires every person or corporation, claiming mining locations upon quartz lodes which shall have produced minerals to the gross value of \$5,000, to file application for patent within one year from the enactment of this bill; and in case no adverse claim be filed, final proof must be made and the land be paid for at the rate of \$5 per acre, within six months after. It is also provided that all applications heretofore made without appearance of an adverse claimant, shall be complete, and the land paid for at \$5 per acre, within six months from the enactment of this bill; and in all cases where adverse claims have been or may be filed, filing for a patent and payment at the rate of \$5 per acre shall be made within six months from the rendition of final judgment.

This bill appears to apply to quartz lodes alone, no reference being made to placer claims. It will certainly have the same effect as the Negley amendment would, if passed. The Negley amendment, however, applied only to the Comstock, while this bill is general and is applicable everywhere, the Comstock included. The new bill contains a clause which will have exactly the same effect as the Negley amendment, as "all applications heretofore made, without the appearance of an adverse claimant, shall be complete and the land paid for within six months."

A number of the mines on the Comstock have applied for patents, and never took them from the office or receipted for them; if the law is passed, these patents must be taken out. Accordingly the boundaries of the claims must be defined, and as the objectionable Sutor Tunnel clause appears in all patents to mines on the Comstock, the owners of the big mines there have a new bill to fight. If there is to be any law compelling miners to take out patents for their claims, such a one as this is very good; since only those which have produced something are compelled to take out patents, and partly prospected claims are left alone.

MOLASSES AND STAMP-HEADS.—"C. H. A." sends us the following item: In looking over a file of the Press for 1867, I notice the account of a fire-proof cellar which was built with earth and molasses, and it reminds me that the Chinese frequently build houses in the same way. I once made a rather queer use of molasses myself. It was in the Silver Sprout mill. One of the stamp shoes could not be kept in; I waited till the mechanics gave it up, and then went at it myself. The socket in the stamp-head was so large that it required a good deal of sacking, besides wedges, to fill it. Under and over each layer of sacking and wedges, I smeared molasses freely, dusting it over with pulverized ore. When that shoe was put in its place it stayed there.

HOLCOMBE VALLEY MINES.—The San Bernardino Guardian gives these items concerning the Holcombe valley mining district: There are now between 300 and 400 miners in the valley. About 30 buildings are in the course of erection. Holcomb enports one hotel, three restaurants, one store, two butcher shops, two laundries, three saloons, one bakery, three carpenter shops, two blacksmith shops, one quartz mill in active operation and one saw-mill. Jamee B. Greene has gone to Grass valley for a 20-stamp-mill, to be put up in Jacoby cañon.

A DECISION has been rendered in the Circuit Court of Nevada, in the case of I. L. Regua, et al., vs. William Blackwood, et al., to the effect that a valid possession of mineral land may be acquired for the purpose of catching tailings, and that such possession cannot be interfered with by other subsequent claimants who assert a right to enter and take the tailings without any title higher than that of the first possessor, upon the ground alone that the land is mineral and therefore open to exploration.

ALMADEN.—Owing to the constant throng of visitors at the Almaden quicksilver mines, to the hindrance of the work, the superintendent has found it necessary to adopt a rule restricting the admission of visitors to the redmition works to Thursdays only. Visitors will not be admitted to the mine at any other time.

A SUIT involving the title to the principal mines in the Pine Flat district will come up for trial at the next session of the Sonoma district court. This suit, in addition to the pecuniary interest involved, will attract attention from the nice questions of law relating to mining locations in Sonoma.

The Central Pacific Railroad Company employ 26 men, watching 30 miles of track across the Sierras. Their business is to travel back and forth on sections of the road, and look out for rocks that are liable to roll down and obstruct the track.

The employee of the Crown Point mine subscribed \$947.60 for the benefit of John Leary, who, two months ago, lost two fingers on his right hand, and was otherwise injured by a premature explosion of giant powder, in that mine.

MINING has been commenced in all the camps in Deer Lodge county, Montana; but the supply of water in many places is still short; consequently but little has been done.

That Quicksilver Monopoly.

One of the recommendations of the Ways and Means Committee on the pending Tariff bill, is to place quicksilver on the free list. Mr. Morrison, of New York, objected to it. He said that last year Spain produced 36,600 flasks, Russia, 11,000 flasks, and Austria, 9,000 flasks. All produced by convict labor, against which well-paid American labor must compete. The entire production of the world is about 90,000—not enough to supply the demand of the world. Our miners want it cheaper; but if they knew the fact that if we do not collect a duty from it, the Rothschilds get the difference, and they would not gain a dollar, they would be the last men in the world to ask us to do it.

"The mines of Spain are owned by the Rothschilds, who are so wealthy and produce so much quicksilver that they establish the price everywhere. Whenever our mines cease to produce what is required here, the Rothschilds send us quicksilver; otherwise they do not. Now, if we take off the duty, the Rothschilds get this 15 per cent. instead of our own bleeding and suffering treasury. This is the whole fact in regard to the matter, and I do not see the policy or philosophy of the charity proposed by the Committee on Ways and Means.

"Now, these gentlemen have been told there is a monopoly among quicksilver producing mines in this country. At one time it was so. Three or four years ago the New Almaden, the principal quicksilver mine in the country, ran behind some \$300,000 or \$400,000, which it owed to the bank of California. That bank was about to foreclose, take possession and own the mine. They made a bargain with the New Almaden mine that they should have the entire production for two and a half years at \$31 a flask. They had no sooner made the bargain than they put the price up to \$85 a flask. The Rothschilds joined them. The miners throughout the country were obliged to pay an enormous price for quicksilver. That monopoly has expired, and none of these men are connected with each other, and there exists no monopoly now. They are entirely distinct, and each American mine is independent of any other. The fact is, there is no quicksilver enough in the world to supply the demand. Our mountains are full of it, and it is an industry that needs protection. We should encourage the searching of our mountains for this metal, which in former days was called a noble metal."

The *Call* quotes these paragraphs and proceeds to state that "the public here do not doubt that a combination exists on this coast to put up the price of quicksilver, for not a discovery is made in California which promises an additional quicksilver supply, which does not draw around the locality speculators. There is great danger that the quicksilver mines of California will all fall into the hands of a single organization; in which case we do not doubt that the supply will be doled out so as to tax the mines to their utmost capacity."

If there is any single organization in this country or in Europe with money enough to buy up all the quicksilver mines in California, and the will to do it, we are very much mistaken. Perhaps the *Call* is not aware that with quicksilver as high as it is, every owner of a quicksilver claim in the State thinks he has a fortune, and wants half a fortune on his chances. They all want to sell out, but they all want heavy prices and do not like it because capitalists are not as enthusiastic as they are.

These "discoveries, which promise an additional quicksilver supply," do not draw speculators, as the *Call* states. The fact is that nine out of ten of the owners of these claims want to sell to parties who can work the mines. It takes labor and money to develop these mines into paying properties, and labor and money to prove whether they are worth being developed. Let a capitalist who intends purchasing "cinnabar," show his head anywhere in the Coast range, and he is forthwith dragged to several hundred locations, all of which are for sale. And this is not all; the owners of these claims may be seen for months at a time in this city, trying to induce capitalists to invest in cinnabar, and not one in fifty succeeds. Furnaces are needed and men are wanted. Neither can be procured without money. The prospectors have no money and can get none, and if the *Call* can point out to them the method by which they can secure the aid of capital, it will do much more good to the mining community than by harping about a monopoly that does not exist.

The price of quicksilver is regulated by the laws of supply and demand. The old monopoly is dead and gone. There are too many mines for one company to control, and too small a production with too large a dividend for the price to be low. The mining interests of the Coast would be greatly benefited, if the price was 60 cents, instead of \$1.35; but growing about "monopoly" will not reduce it. What is wanted, is capital to open out these new mines, and increase the production so as to provoke competition. When this is done, the price will fall; until then, it probably will not. Most of the speculators who have bought into the new discoveries thus far are men who have bought to develop a little and sell to companies for higher prices. These men unfortunately do very little good, since they endeavor to get rid of the property on any representation, whether the claims are worth anything or not. Cinnabar mining is too uncertain to draw out many capitalists who are eager to put their money into it.

Geology of the Emma Mine.

In connection with the report made by Mr. Attwood, Manager of the Emma mine, to which we referred last week, were several diagrams showing certain geological features. We give two of these diagrams this week, designated in the report as plans No. 1 and No. 2. Plan No. 1 is a geological diagram showing anticlinal fold

Fig. 1. Diagram Showing Position of Rocks in which Emma Vein was Found.

and position of rocks in which the Emma vein was found. Plan No. 2 represents transverse and horizontal section, showing shape and size of the ore deposit found in the Emma. In the report to the shareholders Mr. Attwood says: To avoid fatiguing you with scientific details in relation to the large amount of geological data I have obtained and collected from a most careful "study" and also "survey" of the rocks in which your mine was found, I have

the latter and other outside companies. The "slide," from all observations I have so far been able to make, has taken place subsequent to the formation of your ore deposit, and has also been one of great magnitude, judging by the portions so far exposed. Sixth: The portion of the limestone rocks in which your ore deposit was found has evidently been the part upheaved. Small pieces of ore and vein matter are found implanted in the foot wall of your

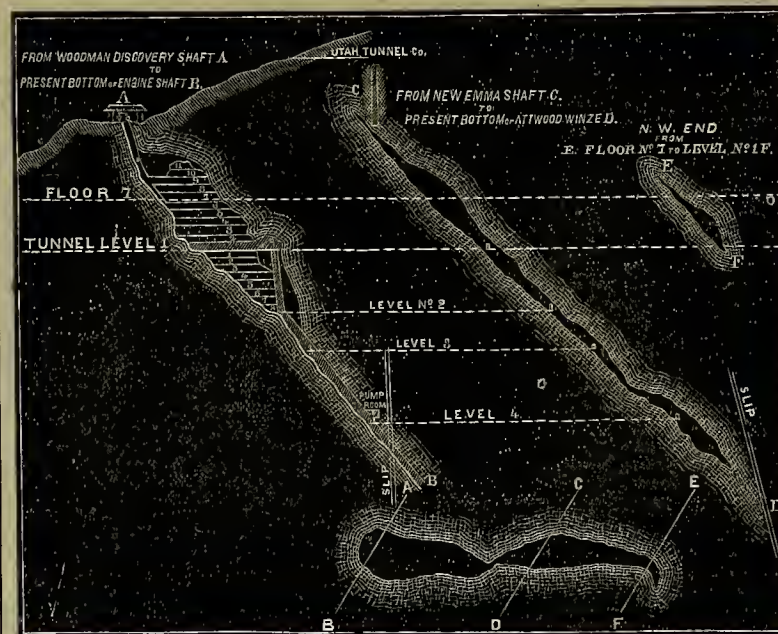

Fig. 2. Transverse and Horizontal Sections of Ore Deposit in Emma Mine.

prepared a geological diagram to accompany this report, which is marked plan No. 1, and I have now come to the following conclusion: First: The Emma vein (or as it ought to be rather termed, "deposit," "it" is a "bed vein," or in other words, a mineral deposit, lying between the enclosing strata of rock, and conformable in its "course" and "angle of dip" to that of the enclosing rocks. Second: The Emma vein lies in a bed of the lower silurian limestone, and in what may be termed metamorphic limestone, in which all traces of fossiliferous remains have been consequently obliterated. Third: Fossils, undoubtedly "corals," have been found in the rocks, which I call middle silurian, but they are so obliterated that it is impossible to determine their geological age with any degree of certainty, therefore I have been compelled to draw my conclusions chiefly from a careful study of the stratigraphical features of the rocks in which your deposit was found, as well as from the neighboring geological sections, which are wonderfully exposed for several thousand feet in height within half a mile of the Emma mine. Fourth: That the porphyritic dyke marked in plan No. 1 has been instrumental in supplying the original cavity (in which your mine was formed) with its minerals,

lower workings, leaving what a miner calls a "dirty tail," showing plainly in which direction the rocks have been thrown. (See plans Nos. 1 and 2). Seventh: A most important feature attending the "pitching out" of your ore deposit is, that all ore and vein matter disappears before the "slide" was cut, in both the engine shaft and finally in the Attwood winze. (See plan No. 2). Eighth: Contrary to the ordinary rules of mineral deposits, the galenas and sulphides are found in the upper workings of your "deposit," and the sulphates, carbonates, oxides, etc., are found in the present lower portions; which fact may be accounted for in a great measure by the water level, and which level may be said to commence at level No. 2. Near the present bottom of the engine shaft I find a natural drainage, but of a limited size, as it will not permit more than 100 gallons per minute to escape; and, from all observations made on the subject, I consider the water finds its way to the surface along the line of the "slide."

EXTENSION OF TIME.—The President has signed the amendment to the mining law of May 10th, 1872, extending the time for the first annual expenditure on mining claims.

The Negley Amendment.

The Supplemental Mining Bill to the Mining Law of May 10th, 1872, providing that the companies on the Comstock lode shall obtain their patents, or in other words define their boundaries, was referred, as is usual, to the Senate Committee on Mines and Mining. When Senator Jones became a member of that committee, objections were made that he was an interested party and should not sit in judgment on the Bill. That these objections were well taken was proved by the subsequent action of the Committee on Mines and Mining, who agreed to refer the Bill to the Senate Judiciary Committee. This latter committee have just made an adverse report on the Supplemental Mining Bill and House amendments thereto, and say they have considered in connection with them various briefs, arguments and views of Sutro and his associates upon one side, and of various mining companies on the Comstock lode in Nevada on the other. The committee then quote the Sutro Tunnel Charter Act of the Legislature of Nevada, April 4, 1865, the agreement between the Sutro Tunnel Company and the Chollar-Potosi Mining Company, April 13, 1866, and the Sutro Tunnel Charter Act of Congress, approved July 25, 1866, and say: It does not appear that Sutro and his associates have complied with the requirements of the contract; but he and his associates have long since commenced the prosecution of said work, have spent considerable money, and have made considerable progress therein. Sutro insists that the mining companies have conspired together to delay and defeat his operations, and have forfeited any equitable right to complain of his non-compliance with the contract; while on the other hand, the companies assert that they have not so conspired, or otherwise acted to his injury, beyond what they were entitled to do for the protection of their own legal rights. The present contract between these parties really turns upon the construction to be given to the Act of Congress of July 25, 1866, above cited; it being declared by Sutro that he has acquired against the occupants of the mines the lawful right to prosecute and complete the tunnel and to collect from the operations of the mines, by force of that Act of Congress, and independent of any title, under the agreement referred to, two dollars per ton and other compensation named in the contract; and the opposite parties contend that if this be so, the Act was passed under misapprehension by Congress, and that they ought to be relieved from the effects of it.

This Act contains no reservation of any power in Congress for its repeal or modification, and the committee are not satisfied that any improper means were used for its passage, or that it was not as well understood as Acts of Congress generally are when they are passed. In this state of things, the companies now ask Congress in effect to relieve them from the operations of said Act, if they are affected by it, and Sutro asks Congress to assist him by further legislation in forcing the companies into an attitude by which he can more easily compel them to pay the two dollars per ton, etc., when his tunnel shall have been completed. It will be seen, therefore, that the respective rights of the parties to this controversy are purely private questions between themselves, depending upon the grant of the Legislature of Nevada, the Act of Congress, and the contracts and business transactions of the various parties. This being the case, the committee are of opinion that the questions at issue are properly those of judicial cognizance, and that under the circumstances it is not the duty of Congress to interfere in aid of either party; but they ought to be left, as all other questions of private rights between citizens should be left, as from time to time they may arise, to the determination of a judicial tribunal or to a settlement between the parties themselves; and as the bill in question, as well as the amendments by the House of Representatives thereto, is deemed on one side or the other to directly or indirectly affect their pending dispute and contested rights, the committee recommend that the bill be indefinitely postponed.

This bill—properly known as the Negley Amendment—was intended to compel the productive mines on the Comstock lode to procure their patents. By obtaining their patents, the boundaries of their claims would be defined, much to the gratification of outside claims, especially to the eastward of the lode, the owners of which fear to take any steps toward obtaining a patent until the rich companies define their boundaries. That the owners of the rich mines do not wish to define their boundaries is very evident from the violent opposition they have made to the bill. This opposition was ostensibly made against it because the patents contain a clause relative to the royalty to be paid to the Sutro tunnel, and the fight was made on that point. But as the companies will probably have to pay this royalty in any case, if the tunnel is ever constructed, and they, of course, know that fact, it is very plain that the opposition to the bill was only maintained so that the boundaries of the claims should not be definitely defined. If these men are working on their own ground, they need not fear to define their boundaries; if they are not, the proper owners of the ground should have possession of it, and get what they can out of it.

McCann, who has been for several weeks prospecting on a quartz vein near what is known as the "Donnybrook Slide," on Sherlock's creek, Mariposa county, unexpectedly discovered a vein of copper.

Silver Mines.

The wealth of silver mines is historic. We are informed by Humboldt, in his Essay Politique, that the yield of the Mexican mines since the Conquest until 1803, had been two thousand and twenty-seven million nine hundred and fifty-two thousand dollars, all of which had been produced from a few central spots, and the mining confined to a comparatively limited circle.

Mexican Mines and Mining.

The register coinage of the mint of Mexico, from the year 1733 to 1860 shows \$1,742,573,107. When we remember that the royalty to the King of Spain, to whom, until the commencement of the 19th century, the Mexican states paid tribute, was one fifth, or 20 per cent. of the yield, and take into consideration the royal monopoly of quicksilver and gunpowder, the result seems astounding.

The Mexican method of mining was crude and simple. The ore, as well as the water from the bottom of the shafts, was generally brought to the surface upon the shoulders of *teneros* (carriers) over ladders. Their *crustas*, or crushing mills and amalgamators, were of the rudest possible character, and were run almost wholly by mule power.

Immense Returns.

The following is the registered yield of a few mines on the American continent:

Biscaña	\$ 16,000,000
Santa Anita silver mine	21,347,210
Valencia silver mine	31,813,486
Rayas silver mine	35,421,014
Veta Madre silver mine	235,935,736
Veta Madre of Guanajuato	800,000,000
Veta Grande of Zacatecas	650,000,000

The Paravallon silver mine, when first opened, produced \$20,000 per day for five years, when a torrent of water from the mountains filled the shafts and swept away the improvements. It was opened again, and for the succeeding ten years yielded \$50,000,000, when it was again abandoned in 1696, and not opened again until 1781, when it was vigorously worked for eight months, the ore taken from it in that period yielding \$11,600,000.

The different members of the celebrated Fagoajo family of Mexico are estimated to have received during fifty years' working of two veins over \$16,000,000 as profits.

The Carmen vein, north of Durango, in the State of Chihuahua, among the mines of *Btopilas*, has produced enormous yields of silver. From this mine, three masses of pure malleable silver were taken, weighing, collectively, 870 pounds.

Silver Mines of High Altitude.

The best silver mines are those of high elevation. It has been the experience in Mexico, and it is a well known fact, that the mines of Great Potosi, which have produced over one thousand millions, are worked at a height exceeding that of Mount Blanc.

Fuller, in his treatise on silver mines, says: "Wherever, in any part of the world, silver mines have been worked, they are worked now, unless from some unexplainable cause. The lack of machinery, the existence of war, and the invasions of Indians have, as in Mexico, familiarized our minds with the idea of abandoned mines. But they have all been abandoned for some other cause than that they have been exhausted. We know of no silver mining regions in the world that have given out."

Inexhaustible Riches.

The mines of Mexico, originally worked by the Aztecs, before the Spanish conquest, are worked still. The mines of the Andes have given forth their wealth for more than three centuries. The mines of old Spain have been worked from the middle ages, and are in working condition now. In Hungary the same mines worked by the Romans before the birth of Christ, still yield their steady increase. The silver mines of Freiberg, in Saxony, worked from the eleventh century, have no diminution. In Bohemia, Tyrol, Norway and Sweden, on the Ural and Atlas mountains, and indeed wherever the discoveries of silver mines have been made, we believe, without exception, the mines continue to be worked to the present day, and are generally more productive now than at any time during their past history. Silver mining, for permanent and rich returns, has had its parallels in no other business.

NEW MACHINERY AT THE CONSOLIDATED VIRGINIA.—An addition has been made to the Consolidated Virginia works, which extends the full length of the west end of the main building. In this will be placed the Burleigh compressor, which is to furnish compressed air for driving the engines and drills in the lower levels of the mine. The compressor will drive two engines (stationed at winzes) and four Burleigh drills. These underground engines will be sufficiently powerful to sink the winzes to the depth of 700 feet. The foundation for the compressor is now being laid. In the addition in which the compressor is now being set up will be placed a large amount of machinery for doing iron work. There will be a large lathe, a planer, a drill and a shaper. This machinery will be driven by an upright engine. All of this new machinery is expected to arrive here shortly.—*Enterprise*.

THE OPTIC NERVE.—By a microscope examination of the retina and optic nerve and the brain, M. Bauer found them to consist of globules of 1-2,800 to 1-4,000 of an inch in diameter, united by a transparent viscid and coagulable gelatinous fluid.—*E. Lovett*.

The Mullins & Ryan Gravel Claim—A Lucky Purchase.

This claim, situated on Central Hill, has been worked for over seven years, during which time a tunnel has been run 1,200 feet in search of the lead, but until lately without success. After spending all their means in what seemed to be a wild goose chase, the proprietors—Messrs. Mullins, Ryan, and the Harkins Bros.—stopped work. One of the partners went to Oregon, one to San Francisco; and, although the other two stayed here, they were unable to make any headway in opening the mine. This was the condition of affairs when Messrs. Dyas and Montgomery bought into the claim, some ten months ago. Already had \$50,000 been expended in searching for the lead, and the prospect was indeed gloomy. Notwithstanding this, after the new proprietors had made a careful survey of the ground, they came to the conclusion that the lead was there, and that they could do what others had failed to do—find it. With an expectation that it would be a work of time and necessitate the investment of much filthy lucre they made the venture. And now comes the strange part of the story. Under the new management the tunnel had not been driven over four feet, when the lead was found and gold was visible in the gravel on all sides. They had struck the famous Blue Lead, one of the "dead rivers" of California, and in which has been found some of the best paying claims in the State. There has been no claim struck in Calaveras for years which will compare in richness with this. The claim is 800 feet in length, and the pay-streak is 110 feet from rim to rim, with a thickness of seven feet independent of the crevices, which are abundant. After the lead was struck there was considerable work required to put the claim in working order, but that is now all finished. The first washing from the lead was cleaned up last week and we are informed amounted to twenty-six hundred dollars. The claim is now paying about twenty dollars a day to the hand. It will undoubtedly last for years, adding much to the prosperity of our county, and encouraging others to venture their capital here.—*Calaveras Citizen*.

CHARCOAL AND BULLION AT EUREKA.—The Eureka Sentinel of the 31st says: The charcoal receipts for the 30 days ending last evening were as follows: Richmond, 74,390 bushels; Hoosac, 50,000 bushels; Ruby, 29,000 bushels; Eureka Consolidated, 90,000 bushels; in all, for the month, lacking one day, 523,300. The bullion product for the same time, with to-day's included (which we have approximated in order to give the full month's returns), has been: Richmond, one furnace 31 days and one 16 day, 877,780 pounds of crude bullion; Eureka Consolidated, one furnace 31 days and one 24 days, 908,600 pounds; Hoosac, one furnace 26 days, 346,000 pounds; and the Ruby Consolidated, one furnace 12 days, 110,000. These figures give a grand total for the month of 2,237,780 pounds or nearly 1,119 tons. Who shall say that these are not encouraging results when we come to consider the great drawbacks against which we have had to contend from the first to the present instant of the month? Eureka has good cause to exult over them. The shipments were: By the Richmond, 255,504 pounds of refined bullion, free from all the base metals but lead; Eureka Consolidated, 603,584 pounds of crude bullion; Hoosac, 132,676 pounds of crude bullion; Ruby, 80,000 pounds; which make in all 1,071,764 pounds for the month, leaving a balance on hand yet to be shipped of 1,166,016 pounds. The bullion shipped through Wells, Fargo & Co.'s Express to the Bank of California, up to last evening, includes 11,834½ ounces, valued at \$10,797.47.

MINING INTERESTS AT EUREKA.—The mining interests are in a very flourishing state, indeed, and every day is adding to the common prosperity. Our mines are, as a rule, richer, better and more extensive, as regards their ore deposits, than they have been known to be at any preceding period in the history of Eureka. These facts are being abundantly evinced by the amount of ore extracted, and also by the quantity of bullion produced and shipped hence to New York, San Francisco and other quarters. The figures, which we give below, too, showing the result produced by six furnaces for the month ending to-day, will add to our testimony in favor of the above proposition, and will, we doubt not, be read with no little interest by those who have been searching for a place of permanent location.—*Sentinel*.

A HUGE NEW MILL.—The Consolidated Virginia Mining Company will shortly erect in this city an immense mill for the reduction of their ores. This mill will stand to the northward of their waste-dump, and will front on F street. The mill building will be 208 feet in length by 190 in width, and it will contain 60 stamps, 30 pans and settlers, and other apparatus in proportion. About 200 machinists and iron-workers at San Francisco are engaged upon the machinery for this mill, and the greater part of it will soon be completed and ready for shipment. The company own several acres of ground in and about where the mill is to be erected, they having bought all the lots and buildings in the vicinity. When this first mill is completed a second of the same size will be erected alongside of it.—*Enterprise*.

The coal production of the United States amounted last year to 45,413,340 tons; the corresponding production in 1872 was 42,749,241 tons.

Let Us Have Figures.

A point is now reached in our mining history when mere statements of the appearance of mines, the size of veins, the character of the ore and the amount of work done have ceased to be of any avail in inducing capitalists to invest in Utah mines; in other words the speculative period has passed away, and we must now come down to business principles if we would secure the co-operation of men of means and energy.

The questions now asked are, what is the daily yield of your mines? What amounts of ore and bullion are you shipping? What is the cost of extraction, smelting, milling, etc.? All indicating that no more gopher holes, salted mines, or other swindles can be palmed off on an excited public. What is needed and what we must demonstrate by actual figures is that profits are being realized from our mining, smelting and milling operations, and until this is accomplished we have but little hope that capital to any great extent will force its way here.

Hitherto there has been too much reticence on these subjects, resulting in great difficulty in obtaining reliable information. Ordinary letters, such as are written in the form of correspondence from the various camps amount to but little in creating an interest in our mining affairs. The day for that kind of information has passed, and instead thereof information must be supplied of a more definite and argumentative character.

To this end we invite the co-operation of superintendents of mines, mills and furnaces throughout the Territory. At all times we shall take pleasure in publishing statements of a statistical character, as it is from these men of business take data for their operations, and such only interest the class of legitimate operators we are seeking to induce to invest in Utah.—*Utah Mining Gazette*.

COLOMA.—On Thursday last, with a friend, we sauntered out for a walk, and almost before we were aware of it, were half way to Coloma, the point where the first discovery of gold in this State was made, and concluded to pay the old mining camp a visit. All that now remains of its former greatness as a flourishing mining camp are two long rows of tumble-down buildings on the principal streets, containing only two stores of general merchandise, two saloons, a hotel, tailor shop, shoe shop, etc. There is but very little mining now done in the vicinity, but agriculture and horticulture are quite extensively and profitably carried on. The town lies in a basin through which passes the South Fork of the American river, surrounded by steep mountains from five to eight hundred feet in height. There are but a few thousand acres of land in this basin, but they have been put to good use, and at this season of the year, leaving out the dilapidation of its main street, Coloma comes very near being a second garden of Eden. The altitude is in the neighborhood of eight hundred feet lower than that of Placerville, and vegetation is fully three weeks farther advanced. They have had ripe strawberries and green peas for several weeks, and we plucked ripe cherries from trees upon the grounds of Robert Chalmers, the celebrated wine manufacturer. The scenery surrounding the town is really enchanting, and no tourist should consider that he had "done" California until he visits Coloma.—*El Dorado Republican*.

THE BLAKE HOSE.—A hose to meet the requirements of fire service must be eminently light, compact and impervious, as well as durable and easily kept in order. Leather hose is heavy and filthy, requiring constant oiling; while the demerits of the "four-ply" gum hose are its extreme bulk and weight, and its rapid decay. Unlined canvas hose is light and strong, but not impervious. Seamless rubber-lined hose does not admit of perfect union between the envelope and its lining. In order to meet this objection, the Blake hose is made by calendaring pure gum through the pores of strong duck, then coating each side with pure rubber, sewing the fabric up and vulcanizing the whole together. Both rubber and duck are mildew-proofed. The new hose is light and strong.—*Journal of Franklin Institute*.

RECIPES FOR GLUE.—1. Powdered chalk, added to common glue, strengthens it. 2. A glue which will resist the action of water is made by boiling one pound of glue in two quarts skimmed milk. 3. For fire and waterproof glue, mix a handful of quicklime with four ounces of linseed oil; thoroughly lixivate the mixture, boil it to a good thickness, and spread it on tin plates in the shade; it will become very hard, but can be dissolved over a fire, like common glue, and is then fit for use.—*Jour. of Ap. Chem.*

Microscopic examinations of thin sections of various rocks is attracting a great deal of attention in Germany, and every mineralogist now supplies himself with a microscope and a cutting or rubbing machine for the manufacture of sections. A recent work by H. Rosenbusch on this subject shows the varieties and peculiarities of the internal structure of rocks, as revealed by the microscope and polariscope.

IMPROVED MODES FOR PREPARING MEDICINES.—In these gelatine, glycerine, and water, together with a certain quantity of medicine, is compounded and poured out on a plate divided into small equal squares. When dry, it is loosened from the plate, and each square forms a dose.

The Mineral Resources of Texas.

The following is from a recent report on the mineral resources of Texas:

Iron Ore.

The iron deposits of Northwestern Texas are the most remarkable character, equalling in extent and richness those of Sweden, Missouri, New Jersey and New York. They include almost every variety: magnetic, spastic, specular and hematitic ores. The largest deposits of magnetic iron ores are situated in Mason, Llano and more western counties.

Coal.

The coal-bearing rocks of Texas occupy an area of not less than 6,000 square miles, embracing the counties of Jack, Young, Palo, Pinto, Eastland, Brown, Comanche, Callahan, Coleman, and extending to the territory of Bexar. The rocks contain the characteristics belonging to the coal measures of Missouri and other Western States. In general appearance this coal resembles that of Belleville, Illinois. The analysis gives: Fixed carbon, 52 per cent.; volatile matter, 36 per cent.; ashes, three per cent. It cokes with a great flame, without changing its form. The development of this valuable mineral is destined to be of great importance to the State.

Anthracites, lighter and more brittle than those of Pennsylvania, have been found in various parts of the State, but I had no opportunity to visit these localities. Lignite, tertiary, and other coals of more recent origin, occupy an area of 10,000 square miles.

Copper.

Copper, covering as it does a large area of country, is almost inexhaustible, and will afford a vast fund of wealth for generations to come. A large portion of the counties of Archer, Wichita, Clay, Haskell, Territory of Bexar, counties of Pecos and Presidio, extending to the Rio Grande, is filled with immense hills of copper ore, some of which have been thoroughly tested, and will yield on the average, 55.40 per cent. of metal. Through some particular localities specimens have been found as rich as 68 per cent., containing besides some silver, oxide of iron, etc.

Explorations of the copper veins over the summits and sides of the hills, justify the conclusion that in the extent of one degree of longitude, along the little Wichita river, hardly a tract of 160 acres could be found without large accumulations of ore upon the surface. The vein leads are parallel with the strata, but there is sufficient evidence that they partake of the nature of true veins.

Lead and Silver.

These two metals are always associated together in this State. The calciferous sand rock, which is the lead bearing rock of Missouri, abounds in Texas, and the varieties found in it here are carbonate of lead, sulphuret of lead and molybdate of lead. The former two always contain such large quantities of silver ore as to be considered silver ore. A sample from a three-foot vein in Llano county, gave a yield of 286 ounces of silver, and 74.45 per cent. of lead. It is the carbonate of lead in combination with the sulphuret, and, owing to the large percentage of the former, will be easily reduced. The indications are very favorable for a large quantity and excellent quality of ore. With a well developed mining industry established here, no other country could compete with this region, so far as regards fuel, construction timber, and materials for building and sustaining a railroad.

Manganese, Cobalt, Nickel and Bismuth.

Leads of manganese, cobalt, nickel and bismuth are often met with. The copper ore contains only 25 per cent. of impurities; is far superior to ferro-sulphuret of copper, or copper pyrites generally worked for in England, and in native copper ores, as found at Lake Superior. It is easily smelted, and the strata in which it is found are more excavated than any other in which copper ores occur.

Petroleum.

Petroleum springs occur over a space of about 50 square miles in Hardin county, and it is probable that large supplies may be obtained by boring.

PLACER.—French Joe and Jos. Sheppard came in last week, bringing with them some coarse gold taken from the bed of Black cañon, on the west slope of the Humboldt range, and about six miles south of Humboldt city. The water was turned out and a small hole was sunk in the bed of the creek, and gold was found in every pan full washed. The gold found is very coarse and rough, and it is the opinion of all who have seen it that it is from a ledge in close proximity to the place where the gold was panned out. They knew nothing about working placer diggings, and they threw away all the fine gold saved in the pan, picking out and keeping only the coarse pieces. They had a set of sluice boxes made, and started back last Saturday, with a wagon carrying tools and provisions enough to last them all summer. Bob. Hazeltt, an old placer miner, accompanied the party to assist in setting up the sluices and opening up the claim. It is their intention to prospect for the ledge the gold is supposed to have escaped from. Wood and water are plenty in the cañon. The boys think they have a good thing.—*Silver State*.

If proper provision is made for expansion, portable engines can be made quite as durable as stationary engines.

1

The Partnership Publication Law.

The announcement that an amendment of the civil code provided that firms not publishing the names and address of their partners, could not maintain any action at law, has taken the commercial community somewhat by surprise, and as there are 18,000 firms in San Francisco, and 30,000 in the State who will be thus obliged to patronize the newspapers unwillingly, this latter will for awhile reap a goodly harvest. The simplest form of statement covering four lines is sufficient to comply with the law of which the following are the provisions:

2,466.—Except as otherwise provided in the next section, every partnership transacting business in this State under a fictitious name, or a designation not showing the names of the persons interested in such business, must file with the clerk of the county in which its principal place of business is situated a certificate stating the names in full of all the members of such partnership, and their places of residence, and publish the same once a week for four successive weeks, in a newspaper published in the county, if there be one, and if there be none in such county, then in a newspaper published in an adjoining county.

2,467.—A commercial or banking partnership, established and transacting business in a place without the United States, may, without filing the certificate or making the publication prescribed in the last section, use in this State the partnership name used by it there, although it be fictitious, or do not show the names of the persons interested as partners in such business.

2,468. The certificate filed with the Clerk, as provided in section 2,466, must be signed by the partners, and acknowledged before some officer authorized to take the acknowledgments of conveyances of real property. Where the partnership is hereafter formed, the certificate must be filed, and the publication designated in that section must be made within one month after the formation of partnership, or within one month from the time designated in the agreement of its members for the commencement of the partnership; where the partnership has been heretofore formed, the certificate must be filed, and the publication made within six months after the passage of this Act. Persons doing business as partners contrary to the provisions of this article shall not maintain any action upon or on account of any contracts made or transactions had in their partnership name, in any court of this State, until they have first filed the certificate and made the publication on herein required.

2,469. On every change in the members of a partnership transacting business in this State under a fictitious name, or a designation which does not show the names of the persons interested as partners in its business, except in the case mentioned in section 2,467, a new certificate must be filed with the County Clerk and a new publication made, as required by this article, on the formation of such partnership.

2,470. Every county clerk must keep a register of the names of firms and persons mentioned in the certificates filed with him, pursuant to this article, entering in alphabetical order the name of every such partnership, and of each partner therein.

The firm of A. L. Bancroft & Co. was the first to comply with the law.

The form recommended by Hon. J. W. Dwinelle is as follows:

CERTIFICATE OF PARTNERSHIP.—We certify that we constitute a partnership, transacting business in this State; its principal place of business is San Francisco, California; its name is Russell & Co., the full names and residence of its members are signed hereunto. May 29, 1874.

JOHN HENRY RUSSELL, of San Francisco, California.
GEORGE WILLIAM JONES, of San Francisco, California.
RICHARD NEALS, of New York City.

IS IT NOT A MISTAKE?—The San Francisco Post says that among the most prominent workers in the whisky interest at Oakland, on election day, was "Mr. Dewey, of the SCIENTIFIC PRESS." We can't think it.—*California Granger*, May 28th.

It was undoubtedly a mistake on the part of the reporter of the Post. This being understood, and Mr. Dewey's position in the temperance movement well known, no attention was given to the matter. But when parties who are well acquainted with Mr. Dewey's record and present position in temperance matters, parade this mistake in their paper, and thus involve the subject in doubt, his friends, during his absence from the city, feel called upon to notice the matter, and give it an unqualified denial.

In speaking of the cost of the pump in the Emma mine, in our article last week, the types made us say the pump would cost £30,000. We intended to say the pump would cost \$30,000.

The mint will be closed for repairs on next Tuesday, the 16th instant, and will resume business again on the 2d of July. Fine gold deposits, however, will be received during the time.

R. W. RAYMONN, U. S. Commissioner of Mining Statistics, arrived in San Francisco this week. He is on this coast on his annual tour among the mining districts.

NINETEEN flasks of quicksilver were received in Napa from the California mine Thursday.

General News.

NEWSPAPER POSTAGE.—The Postal Appropriation bill, as reported from the Senate Committee, contains an amendment providing that postage shall hereafter be prepaid on all mailable matter at the time of mailing. Efforts are being made to defeat this, or postpone its taking effect until a year after its passage; otherwise, newspapers taking subscriptions by the year will be compelled to prepay postage on the entire mail addition, although their contracts with the subscribers were made with the condition that the latter should pay the postage. The proposition is a tax upon knowledge, and so bungling in its provisions as to greatly interfere with the celerity of conveying news through the mails. It is altogether unworthy of the age, and utterly fails to introduce any economy in the mail service.

THE CIVIL RIGHTS BILL appears to be effectually killed. At least Grant will veto it if passed. Some people are so uncharitable as to think the President is moved in opposition to it by his desire thereby to make capital for himself in view of a nomination for a third term. It is also said that Dr. Sears, agent of the Peabody education fund, has declared that its passage, in its present form, would break off the Peabody schools throughout the Southern States. We can't see how.

SECRETARY BRISTOW, the head of the Treasury Department, starts out with the determination of making a thorough reform in the management of that office. The earnestness and determination which he evinces, fill his subordinates with much astonishment. It is to be hoped that he will hold out as he has begun. If he does so, he will save many millions for this country every year. He is evidently such a man as he claims to be—one without any "deficiency in backbone."

ROCHEFORT MAKES GOOD TIME.—For some reason, better known to himself, Rochefort, the great French Communist, seems determined to lose no time in placing himself in close proximity to his own stamping ground. His stay in New York was nearly as brief as it was in this city. Nothing but the British Channel now separates him from La Belle France. He has evidently discovered that communism is not looked upon with any degree of favor in this country.

A PEOPLE'S RAILWAY.—Senator Logan has introduced a bill to incorporate a commercial railway, with four or more tracks, between New York and Chicago and St. Louis, with a capital of \$200,000,000; tariffs not to exceed ten cents per bushel for grain and thirty-six cents per barrel for flour from Chicago to New York. A petition signed by 20,000 citizens of Illinois has been presented to Congress, through Senator Logan, asking for the passage of such a bill.

REGULATIONS FOR KILLING PEOPLE.—It is said that the International Congress, about to assemble at Brussels, will probably enact a new code to govern belligerent nations during war, and will also specify what kind of arms may be legitimately used, make regulations for treatment of prisoners, etc.

THE CATHOLIC CHURCH.—The priests of Rome are credited with saying that the Catholic church has gained more during the past two centuries in America than it has lost in all other countries.

TIMBER.—It is estimated that the number of railroad ties in present use in the United States is 150,000,000. A cut of 500 ties to the acre is above the average; and it therefore has required the product of 750,000 acres of well timbered land to furnish the supply. Railroad ties last about five years; 30,000,000 ties are used annually for repairs, taking the timber from 150,000 acres. The manufacture of rolling stock disposes of the entire yield of 350,000 acres, and a full supply of 500,000 acres more every year. Our railroads are stripping the country at the rate of 1,000,000 acres per annum.

THE surveyors of the Nevada City and Colfax Railroad are now surveying between Bear river and Greenhorn. They have run several lines between these points, and have not concluded which one to adopt.

THE contract for building the road from Healdsburg to Pine Flat has been awarded to B. B. Robinson & Son, of Napa county, their bid—\$4,494—being the lowest. The work is to be completed within 90 days.

THE Swatara, with 200 persons on board, has left New York for the South Pacific to watch the transit of Venus there. Twenty-six of the party were scientific men.

THE Eureka gravel mine, at Relief hill, Nevada county, uses 100 inches of water, and is paying at the rate of \$20 per day to the land.

THERE is considerable excitement at Crescent City about beach mining. A large number of claims have already been located.

A rich strike is reported at Cement hill, Nevada county. Streaks of gold are visible all through the cement.

THE cars for the Stockton and Lone Narrows-gauge Railroad will be manufactured in Stockton.

THE Weaverville ditch is about completed.

The Vanishing Forests.

The public have been called upon of late to consider the fate that seems to await our native forests, and the probable consequences that would follow their destruction. It is generally admitted that the subject is worthy of the serious consideration claimed for it, and the public are not disposed to leave it in the hands of mere theorists. It has become a subject of popular interest, and even though no specific remedy is offered, the sense of individual responsibility, and the expressed demands of public sentiment, will establish a more economical use of timber and do much toward preventing actual waste.

This is commendable; but with the prudent forethought and sense of responsibility manifested here, it is evident that an alarm, which can produce no good and which is also unreasonable, is blending itself with this subject.

The bugbear that the destruction of our forests is to entail upon the country an almost perpetual drought is already creating a degree of uneasiness in the public mind. The fact that forests have a beneficial effect on the surrounding country, by producing an increase of rain, is indisputable; and the prospect of their entire removal, with nothing substituted to perform this office, would be truly alarming. But it is confidently asserted, and the opinion is gaining ground, that railroad tracks and telegraph wires are already producing, in the new countries which they are intersecting, effects corresponding with those for which the forests have been accredited.

A change, of this character, is already noticed in the climate of the plains, which, it is claimed, is produced by the Pacific railroad. The same result has been remarked in other sections of the west. It is also claimed that the severity of thunder-storms is materially modified by the same influences—the iron rails and telegraph wires attracting the electric current and diffusing an equality through the atmosphere.

No greater stretch of imagination is required to find a remedy for the supposed impending evil that is called into play in the anticipation of it. And, without any aid from imagination, but with the light of science alone, we may safely reckon on a supply of minerals from the spots that we are denuding of their forests that will, to a great extent, supply their loss—furnishing materials for much that is now constructed of wood only, and throwing into disuse much that is now considered indispensable.

Are we not justified in trusting in Providence to supply the actual wants of each generation, or of the world at large, as well as those of the isolated individual?

TUOLUMNE REUNION.—The Tuolumne Reunion Association will hold their seventh annual picnic at Badger's Park, Oakland, on the 17th inst. This association is composed of residents and ex-residents of "old Tuolumne" who meet once a year and talk over old times when "they were in the mine." The officers this year are: President, L. P. McCarty; Vice President, C. B. Rutherford; Secretary, C. E. McCusker; Treasurer, W. G. Dinsmore. At the picnic next week, musical and literary exercises will be held in the Pavilion, when free and easy speeches are expected from many of the members. The musical part of the programme is made prominent, and Miss Fannie Marston, Prof. Carmine Morley, Mrs. Julia A. Cameron and Mr. C. Makin, will render the vocal music. Robert Ferral is to deliver the oration, and the exercises will conclude with dancing. Wallcott's band having been engaged to furnish the necessary music.

THE snow is off the Mineral King mines, Tulare county, and travel is increasing in that direction.

THE coal mines in Contra Costa county are turning out unusual quantities.

PATENTS & INVENTIONS.

A Weekly List of U. S. Patents Issued to Pacific Coast Inventors.

(FROM OFFICIAL REPORTS FOR THE MINING AND SCIENTIFIC PRESS, DEWEY & CO., PUBLISHERS AND U. S. AND FOREIGN PATENT AGENTS.)

By Special Dispatch, Dated Washington, D. C., June 9, 1874.

FOR WEEK ENDING May 26, 1874.

MECHANISM FOR LOADING AND UNLOADING LUMBER.—Hans P. Tothammer and Gustav Osborn, S. F., Cal.

BUTTON-HOLE SEWING MACHINE.—Justin J. Graff, S. F., Cal.

QUARTZ MILL SHOE.—Joseph G. Kittridge, S. F., Cal.

BRAKE FOR VEHICLES.—Elbridge G. Lancelotti, Yountville, Cal.

GANG PLOW.—Gideon J. Overshiner, Hollister, Cal.

—The patents are not ready for delivery by the Patent Office until some 14 days after the date of issue. NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & CO., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest time possible.

DEWEY & CO.

American & Foreign Patent Agents,

OFFICE, 338 MONTGOMERY STREET, S. F.

PATENTS obtained promptly; Caveats filed expeditiously; Patent reissues taken out; Assignments made and recorded in legal form; Copies of Patents and Assignments procured; Examinations of Patents made here and at Washington; Examinations made of Assignments recorded in Washington; Examinations ordered and reported by Telegraph; Rejected cases taken up and Patents obtained; Interferences prosecuted; Opinions rendered regarding the validity of Patents and Assignments; every legitimate branch of Patent Agency Business promptly and thoroughly conducted.

Our intimate knowledge of the various inventions of this coast, and long practice in patent business, enable us to abundantly satisfy our patrons; and our success and business are constantly increasing.

The shrewdest and most experienced Inventors are found among our most steadfast friends and patrons, who fully appreciate our advantages in bringing valuable inventions to the notice of the public through the columns of our widely circulated, first-class journals—thereby facilitating their introduction, sale and popularity.

Foreign Patents.

In addition to American Patents, we secure with the assistance of co-operative agents, claims in all foreign countries which grant Patents, including Great Britain, France, Belgium, Prussia, Austria, Victoria, Peru, Russia, Spain, British India, Saxony, British Columbia, Canada, Norway, Sweden, Mexico, Victoria, Brazil, Bavaria, Holland, Denmark, Italy, Portugal, Cuba, Roman States, Wurtemberg, New Zealand, New South Wales, Queensland, Tasmania, Brazil, New Grenada, Chili, Argentine Republic, AND EVERY COUNTRY IN THE WORLD where Patents are obtainable.

No models are required in European countries, but the drawings and specifications should be prepared with thoroughness, by able persons who are familiar with the requirements and changes of foreign patent laws—agents who are reliable and permanently established.

Our schedule prices for obtaining foreign patents, in all cases, will always be as low, and in some instances lower, than those of any other responsible agency.

We can and do get foreign patents for inventors in the Pacific States from two to six months (according to the location of the country sooner than any other agents.

Home Counsel.

Our long experience in obtaining patents for inventors on this Coast has familiarized us with the character of most of the inventions already patented; hence we are frequently able to save our patrons the cost of a fruitless application by pointing them to the same thing already covered by a patent. We are always free to advise applicants of any knowledge we have of previous applications which will interfere with their obtaining a patent.

We invite the acquaintance of all parties connected with inventions and patent right business, believing that the mutual conference of legitimate business and professional men is mutual gain. Parties in doubt in regard to their rights as assignees of patents, or purchasers of patented articles, can often receive advice of importance to them from a short call at our office.

Remittances of money, made by individual inventors to the Government, sometimes miscarry, and it has repeatedly happened that applicants have not only lost their money, but their inventions also, from this cause and consequent delay. We hold ourselves responsible for all fees entrusted to our agency. The principal portion of the patent business of this coast has been done, and is still being done, through our agency. We are familiar with, and have full records of, all former cases, and can more directly judge of the value and patentability of inventions discovered here than any other agents.

Situated so remote from the seat of government, delays are even more dangerous to the inventors of the Pacific Coast than to applicants in the Eastern States. Valuable patents may be lost by the extra time consumed in transmitting specifications from Eastern agencies back to this coast for the signature of the inventor.

Confidential.

We take great pains to preserve secrecy in all confidential matters, and applicants for patents can rest assured that their communications and business transactions will be held strictly confidential by us. Circulars free.

Engravings.

We have superior artists in our own office, and all facilities for producing fine and satisfactory illustrations of inventions and machinery, for newspaper, book, circular and other printed illustrations, and are always ready to assist patrons in bringing their valuable discoveries into practical and profitable use.

DEWEY & CO.,

United States and Foreign Patent Agents, publishers Mining and Scientific Press and the Pacific Rural Press, 338 Montgomery St., S. E. corner of California St., San Francisco.

METALS.

WEDNESDAY M., June 10, 1874.

The Metal market is dull. Copper is lower. Quicksilver is steady at \$1.35 3/4 lb.

American Pig Iron, 100 lb.	40 00
Scott's Pig Iron, 100 lb.	40 00
White Pig, 100 lb.	50 00
Reddish Bar, good assortment, 100 lb.	3 1/2
Roller, No. 1 to 4	5 1/2
Plate, No. 5 to 9	5 1/2

NOTICE.

We certify that the partnership of Dewey & Co., doing business in San Francisco, California, is composed of Warren B. Ewer, George H. Strong and John L. Boone, all of whom reside in the city and County of San Francisco, and Alfred T. Dewey, who resides in Oakland, Alameda County, Cal.
San Francisco, Cal., June 3d, 1874.

WARREN B. EWER,
GEORGE H. STRONG,
JOHN L. BOONE,
ALFRED T. DEWEY.

STATE OF CALIFORNIA,
CITY AND COUNTY OF SAN FRANCISCO.

On this June 3d, 1874, before me, F. O. Wegener, a Notary Public in and for said City and County, personally appeared Warren B. Ewer, George H. Strong, John L. Boone and Alfred T. Dewey, known to me to be the persons whose names are subscribed to the within instrument, and acknowledged to me that they executed the same.

Filled June 5. W. H. NEY, County Clerk,
By W. STEVENSON, Deputy.

In witness whereof I have hereunto set my hand and affixed my official seal, the day and year first above written.
JUN-4

F. O. WEGENER, Notary Public.

BRONZE TURKEYS.
GOBBLE, 43 lbs. HENS, 20 to 25 lbs.
Emden Geese.
(Fifty-eight to sixty lbs. at maturity.)
EGGS FOR SALE NOW.
Bramahs, Lephors, Hondans, Etc.
Send for Price List and Illustrated Circular. Address,
M. EYRE, Napa, Cal.
Eggs for Hatching, packed to travel safely by rail or stage and hatch after arrival.

A LECTURE TO GENTLEMEN

-BY-

BARLOW J. SMITH, M. D.,
Of the Allo-Hygenopathic Institute, 635 and 637
California street, San Francisco, California.

On the "Causes of Nervous Debility and Premature Decline." Also, "Twenty Years' Experience in Reform Medication," treating upon disease in its various forms, the Cause, Prevention and Cure, home treatment, etc. The two sent postpaid upon receipt of 25 cents.
18v28-3m

To Mining Secretaries.

An amendment to Section 336 of the California Codes taking effect July 1st, 1874, provides that in addition to the regular publication of the assessment and sales notices as heretofore,

PERSONAL NOTICE

Must be served as provided in the following quotation from the law:

"The notice must be personally served upon each stockholder, or in lieu of personal service, must be sent through the mail, addressed to each stockholder at his place of residence, if known, and if not known, at the place where the principal office of the Corporation is situated."

The above refers to this ASSESSMENT NOTICE only. Advertisers in the MINING AND SCIENTIFIC PRESS will be furnished with copies of assessment notices printed on slips suitable for serving personal notices under this law at short notice.

DEWEY & CO., Publishers.

June, 1874.

Mining and Other Companies.

Owing to the time necessary to mail the present large edition of the M. & S. Press, we are obliged to go to press on Thursday evening—which is the very latest hour we can receive advertisements.

Calaveras Gold Mining Company—Location of principal place of business, San Francisco, State of California. Location of works, Washington Mining District, Calaveras county, State of California.

Notice is hereby given, that at a meeting of the Directors, held on the 18th day of May, 1874, an assessment (No. 3) of fifty cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of the Company, in San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 16th day of June, 1874, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Wednesday, the 8th day of July, 1874, to pay the delinquent assessment together with costs of advertising and expenses of sale.

Office—No. 318 California street, San Francisco, Cal. (Room No. 13). m16

Continental Silver Mining Company—Location of principal place of business, San Francisco, California. Location of works, Hamilton, White Pine County, Nevada.

Notice is hereby given, that at a meeting of the Directors, held on the 18th day of May, 1874, an assessment (No. 4) levied on the fourth day of May, 1874, the several amounts set opposite the names of the respective shareholders, as follows:

Names.	No. Certificate.	No. Shares.	Amount.
J. R. Foster	67	1	\$1 20
A. W. White	108	11	13 20
G. O. Arnold	258	20	24 00
E. F. Oillespie	272	20	24 00
R. M. Clark	275	20	24 00

And in accordance with law, and an order of the Board of Directors, made on the 4th day of May, 1874, so many shares of each parcel of stock as may be necessary, will be sold at public auction at the office of the Secretary, on Tuesday, the 30th day of June, 1874, at the hour of 12 o'clock A. M., of said day, to pay said delinquent assessment thereon, together with costs of advertising and expenses of sale.

M. BLANKENBURG, Secretary.

Office—No. 118 Front street, San Francisco, Cal. jn13

Diamond Silver Mining Company—Location of works, East Tindie Mining District, Juab County, Utah Territory. Principal place of business, San Francisco.

Notice is hereby given, that at a regular meeting of the Board of Directors, held on the 18th day of April, 1874, the several amounts set opposite the names of the respective shareholders as follows:

Names.	No. Certificate.	No. Shares.	Amount.
Wm Sherman, Trustee	7	550	\$55 00

N. Seibert's Eureka Lubricators.

THE HIGHEST PREMIUM

Awarded by the Mechanics' Institute Fair, San Francisco, and State Fair, Sacramento, 1871.

These Lubricators are acknowledged by all engineers to be superior to any they have ever used; feed constantly by pressure of condensed water, supplied by pipe A, regulated under the oil by valve J, and forced out through check valve and pipe B into the steam pipe C; it then becomes greasy steam, passed to all the valves and cylinder at every stroke of the engine; glass tube I indicates amount used per hour. Packing on rods and stems lasts longer, and the rings on the piston will not corrode. One pint of oil will last from three to six days, according to speed and size of engine; I, sliding gauge; K, valve to shut off when engine stops; H, F, valves to shut off in case of frost; steam does not enter the cup; it is always cool; warranted to give satisfaction. Patented February 14, 1871. Made by California Brass Works, 125 First street, S. F. 24v28-tf

THE SELDEN DIRECT-ACTING STEAM PUMP,

A. CARR. Manufacturer & Proprietor.

Patented

Aug. 2d. 1870.

Dec. 20th, 1870.

Combining simplicity and durability to a remarkable degree. Its parts are easy of access, and it is adapted to all purposes for which Steam Pumps are used.

As a Mining Pump it is Unsurpassed.

TO HYDRAULIC MINERS.

I warn Hydraulic Miners not to be misled by the advertisement of Mr. F. H. Fisher. Said Fisher has been beaten in every suit to which he has been a party (respecting Patent Rights on Hydraulic Machines), whether as plaintiff or defendant.

His patrons have already paid over Five Thousand Dollars for license to use machines purchased of the self styled

"Only Reliable Party in the Business Who Protects His Customers."

Fisher's Machine is worthless unless the discharge pipe is furnished with appliances, the patent for which is owned by Messrs. CRAIG, and which Fisher is enjoined from making.

The Machine itself is also an infringement on another patent owned by the same parties.

All persons infringing on either of these patents

WILL BE PROMPTLY PROSECUTED.

I am sole LICENSEE to sell Machines manufactured under CRAIG's, Rice's, Macey's and Hoskin's patents.

I Guarantee Full Indemnity to all my Customers.

Machines of all sizes always on hand.

If you want a Machine that will give satisfaction, and do not want to pay for it twice over, buy an Improved LITTLE GIANT.

For further particulars apply to

STEAM ENGINES AND BOILERS

Of all sizes—from 2 to 60-Horse power. Also, Quartz Mills, Mining Pumps, Hoisting Machinery, Shafting, Iron Tanks, etc. For sale at the lowest prices by
10v27-1f J. HENDY, No. 32 Fremont Street.

California Assay Office—J. A. Mars & Wm. Ireland, Jr., Chemists and Assayers, Rooms 47 and 48 Merchants' Exchange, San Francisco. Analysis of Ores, Mineral Waters, Etc. 8v28-8m

OVER \$3,500 PER MONTH SAVED BY THE USE OF HENDY'S IMPROVED CONCENTRATOR.

Can be seen at the Manufactory, 32 Fremont Street, San Francisco.

JOSHUA HENDY, Esq.—Dear Sir:—As a practical miner and millman, I take pleasure in recommending the use of your Concentrators in all mills where gold or silver ores are reduced. No mills should be without them for the following reasons:

- 1st. They are good sizers (no perfect concentration in pulverized ores can be effected without first sizing).
- 2d. The best Concentrator I have ever known—(the concentrated stuff only containing 5 per cent. of sand).
- 3d. They are good amalgamators, light (feather) particles of amalgam and particles of coated gold, by attrition are brightened, and from their specific gravity and the action of the pan, fall to the bottom and adhere.
- 4th. They require but little power and attention to run them, and with ordinary care will last for years.

I have been familiar with the workings of your Concentrators for four years past; have run them myself in the North Star Mine, Grass Valley; am familiar with their practical workings on the Empire Mine, Grass Valley; St. Patrick, Placer Co.; St. Lawrence, El Dorado Co.; Oaks and Reese, Mariposa Co., and most cheerfully give you this testimonial. For further information you are at liberty to refer to,

Yours respectfully,

409 California street, or Cosmopolitan Hotel.

SAN FRANCISCO, April 27, 1874.

JAS. H. CROSSMAN, M. E.

OFFICE SUPERINTENDENT OF KEYSTONE CON. M. CO., AMADOR, AMADOR COUNTY.
MR. J. HENDY—Dear Sir:—In answer to your inquiries as to your concentrators furnished our company last July, I would say that I am more than pleased with them; and the saving to the company has been over \$3,500 per month more than with the blankets and buddies formerly in use.

O. C. HEWITT, Supt.

References:

Reference is made to the following mills, some of which have had HENDY'S CONCENTRATORS in use for over four years:

EMPIRE MILL (3 Concentrators)	Grass Valley, Nevada County.
NORTH STAR M. & M. CO. (3 Concentrators)	Grass Valley, Nevada County.
VULTURE CO. (3 Concentrators)	Prescott, Arizona.
NOYES & CO'S MILL (2 Concentrators)	Prescott, Arizona.
LUCY MINING CO. (3 Concentrators)	Owyhee District, Idaho.
EL TASTE CO. (3 Concentrators)	Sonora, Mexico.
ST. LAWRENCE MILL	El Dorado Co.
ST. PATRICK MILL	Newcastle, Placer Co.
JULIAN MILL	Newcastle, Placer Co.
VIRGIL MILL	Oregon.
KEYSTONE MILL (2 Concentrators)	Amador Co.

CAUTION—All of HENDY'S PATENT CONCENTRATORS are marked thus: "J. HENDY, Patented April 17th, 1868, and May 19th, 1868."

For full description send for Circular. Orders or letters of enquiry, address,

JOSHUA HENDY, San Francisco.

Office and Works, 32 Fremont street.

CAST STEEL SHOE AND DIE COMPANY,

OFFICE—Room 28, Hayward's Building, 419 California St., S. F.
Patented CAST STEEL SHOES & DIES for Quartz Mills.
Price, 20 cents per Pound.

CAST STEEL DIE.

An improvement greatly needed—being Stronger, more Durable and Economical than Cast Iron; as the Dies, when worn down, can be welded to the Shoes as easily as bar steel; never break, keep their full striking surface. Battery of five shoes crushes one-ton more ore in 24 hours than Cast Iron Shoes, will wear as long as four sets of Cast Iron shoes, and can be worn down to $\frac{1}{8}$ inch in thickness. The studs can be welded into Picks, Hammers, etc.

—ALSO—
Cast-Steel Tappets, Cams, Hammers, Gearing and Castings

OF ALL KINDS, A SPECIALTY.
It takes forty days to fill orders.

CAST STEEL SHOE.

Metallurgy and Ores.

Varney's Patent Amalgamator.

These Machines Stand Unrivaled.

For rapidity pulverizing and amalgamating ores, they have no equal. No effort has been, or will be made, to have them constructed in the most perfect manner and of the great number now in operation, not one has ever required repairs. The constant and increasing demand for them is sufficient evidence of their merits. They are constructed so as to apply steam directly into the pulp, or with steam bottoms, as desired.

This Amalgamator Operates as Follows.
The pan being filled, the motion of the miller forces the pulp to the center, where it is drawn down through the aperture and between the grinding surfaces. Thence it is thrown to the periphery into the quicksilver. The curved plates again draw it to the center, where it passes down, and to the circumference as before. Thus it is constantly passing a regular row between the grinding surfaces and into the quicksilver, until the ore is reduced to an impalpable powder, and the metal amalgamated.

Settlers made on the same principle excel all others. They bring the pulp so constantly and perfectly in contact with quicksilver, that the particles are rapidly and completely absorbed.

Mill-men are invited to examine these pans and settlers for themselves, at the office, 229 Fremont Street, San Francisco.

Important to Miners and Mill Men.

Silver-Plated Copper Amalgamating Plates, for Saving Gold.

Of all sizes and in any quantity, furnished to order. Full instructions sent for operating. Particular attention given to plating goods for Builders, Plumbers, etc. Hotel and Restaurant work repaid.

Morris' Settler and Amalgamator. PATENTED MARCH 25, 1873.

An important improvement in milling. Cheap, light, efficient and durable. Gains Quicksilver on working tailings. Is discharged from the surface in the center instead of the side, by means of a Siphon which extends to near the center of the Settler. Heaviest casting weighs only 135 pounds. The sides and bottom of the Settler are made of wood, as also Mullers, placed vertically—the friction of which brightens the quicksilver. One of these machines is in daily operation at No. 616 Merchant's street, (basement), San Francisco. Parties desiring information as to rights of use, purchase, etc., can address,

of "Garratt's Patent Improved Journal Metal." Highest
Market Price paid for OLD BELLS, COPPER AND BRASS.

THE ONE-PLUNGER JIG,

Delivered on R. E. Car at Denver, Col.,
or St. Louis, Mo.

CONTAINING SIX SIEVES, END TO END.

Separate in one and the same operation—1. galena
and sulphide of silver; 2. pyrites or blende; 3. tailings,
containing no valuable parts; or, 1. gold; 2. pyrites; 3.
tailings (quartz, etc.) containing no valuable parts; or,
1. copper; 2. tailings, containing no valuable parts.
The One-Plunger Jig can be combined with existing
stamp-mills with highly important advantages, as after
amalgamation it will recover completely all fine metals
and all base ores and all mercury out of tailings. It
concentrates all fine metal ores to such cleanliness that
low grade ores can be shipped, after concentration, as
first-class ores. Its feed and discharge are automatic.
Its construction offers better guarantee against loss and
repairs than any other apparatus in use. For particulars,
apply to the inventor, F. CAZIN,
Mining and Civil Engineer, Denver City, Col.
L. Box 2226. 13v28-1y

GIANT POWDER.

Patented May 26, 1868.

THE ONLY SAFE BLASTING POWDER IN USE.

GIANT POWDER, NO. 1,

For hard and wet Rock, Iron, Copper, etc., and Submarine Blasting.

GIANT POWDER, NO. 2,

For medium and easy Rock, Lime, Marble, Sulphur, Coal, Pipe Clay and Gravel Bank Blasting, Wood, etc.

Its EXCLUSIVE use saves from 30 to 60 per cent. in expenses, besides doing the work in half the time
required for black powder.

The only Blasting Powder used in Europe and the Eastern States.

BANDMANN, NIELSEN & CO.,

General Agents, No. 210 Front Street.

THE SECOND ANNUAL EXHIBITION

—OF THE—

Inter-State Industrial Exposition

OF CHICAGO.

Will Open September 8th, and Close October
10th, 1874.

SPECIAL FEATURES for this year are MACHINERY IN
OPERATION, and PROCESSES OF MANUFACTURE. The
largest and best Exhibition Building on the Continent.
The most liberal arrangements for Exhibitors in every
class, and the best and cheapest method of advertising
for all Artisans, Manufacturers and Inventors. Space,
Steam Power, and Shafting free. Applications should
be made, as early as possible, to

JOHN P. REYNOLDS, Sec'y.

Chicago, May 25th, 1874.

MINING AND SCIENTIFIC PRESS

An Illustrated Journal of Mining, Popular Science and General News.

BY DEWEY & CO.,
Patent Solicitors.

SAN FRANCISCO, SATURDAY, JUNE 20, 1874.

VOLUME XXVIII
Number 25.

Academy of Sciences.

The regular semi-monthly meeting of the California Academy of Sciences was held on Monday evening last. The President, Professor George Davidson, who has just returned from the East, was in the chair. The following new members were elected: Charles T. Dake, J. G. Lemmon, A. E. Head (Life), H. W. Hargrave and Jas. W. Winter.

Mr. W. N. Lorkington presented to the museum choice cases of insects and some alcoholic specimens.

Mr. Dameron presented a lizard, from China, used for medicinal purposes; also, fossil from Forest Hill, Placer county.

Maj. Wm. Ford presented, through Barry & Patton, a supposed weight for distension of thread used in spinning; an aboriginal stone implement, found 20 feet beneath the surface, in cement gravel, at Martinez, Contra Costa county, Cal.

James Lick presented some fragments or pieces of the battle flag, which waved over Fort McHenry, during its bombardment, on the 13th and 14th of September, 1814. This gift will be referred to more at length in another issue.

A number of donations to the library were received; among them, 100 volumes of books, from Chas. L. Weller.

Judge Hastings read a paper in reference to the late manifestations in Oakland.

Dr. Forgeaud read a continuation of his former papers on evolution.

The President called the attention of the members to some phenomena which he observed at the Naval Observatory, while looking at the artificial observation of the transit of Venus. At the time of the earlier observations of this planet, there was a doubt as to a phenomenon which showed an apparent adherence of the limb of Venus to the edge of the sun in the internal contact. This was known as the "black drop," when Venus showed an irregular ephemerical condition. As soon as Professor Davidson saw the artificial Venus, he recognized the cause of this thing. We see it every

day in the work of the Coast Survey. It is simply the undulation of the atmosphere when it is surcharged with aqueous vapor. At an elevation of 7,000 or 10,000 feet, where the atmosphere is attenuated, this is not apparent. In observations taken lately in the Sierras, the sun was sharply outlined, but this was at a high elevation. The President stated that he had no hesitation in saying that former theories on this subject were incorrect, and that the undulation of the atmosphere when filled with aqueous vapor is the true cause. If the morning is dark and cloudy, the artificial Venus can be seen with a sharp contact; but when the clouds broke away and the aqueous vapor was heated up, the "black drop" could be seen. The transit of Venus must accordingly be observed at a high elevation, for there they will be enabled to determine within eight or ten seconds the actual time of contact.

The President also stated that Mr. Mumford, of the Telegraph Co., had shown him an instrument for the transmission of musical sounds along a telegraph wire. He himself heard distinct musical sounds sent 800 miles. He has asked Mr. Mumford to extend a wire to the Academy's building, so as to show the members this remarkable invention. A detailed description of the instrument could not be given until patents were obtained.

The President then introduced Prof. E. S. Morse, of the Peabody Museum, in Salem, who spoke a short time, congratulating the members of the Academy in their prosperity. His remarks were well received.

In referring to the death of Leander Ransome, a member of the Academy, the President said: Col. Leander Ransome's name appears on the records at the second meeting of the organization of the Academy of Sciences, April 11th, 1853, and from that time onward took an active part in the work of the Academy. On January 5th, 1854, he was elected Second Vice-President. January 7th, 1856, elected President and continued to preside as first officer until January, 1867—11 years.

His scientific papers, though few, yet his labors in the cause of science and his warm

QUICKSILVER MINES are being worked in Santa Inez Valley, seven miles north of Santa Barbara, which are pronounced by Wm. D. Brown, an expert, who has seen all the well known cinnabar deposits in Mexico and the

Improved Radial Drill.

We illustrate this week an improved radial drill, manufactured by the New York Steam Engine Co., 98 Chambers street, New York. This machine is capable of drilling to the center of 7 feet when the head is at the outer end of the jib. The head has a movement of 3 feet toward the center of the column, and with the exception of the space required for the driving belts, the jib may be swung completely around the column, and holes drilled at any desired point in the revolution.

The manufacturers furnish, with extra charge, when desired, a square table which acts as a cupboard, and has slots on four sides for holding

knees or angle pieces, or any irregular piece of work. The cone has four changes for a four-inch belt. The drilling spindle is of steel, 2 inches diameter, with 12 inches traverse. The ratio of speed between the cone pinion and the drilling spindle is over 6 to 1.

The feed is self-acting, with three changes; is so arranged as to be instantly disconnected and operated by hand, whenever desired. The base of this machine is fitted for bolting large work upon it, and is further provided with an adjustable revolving table 28 inches diameter, which can be raised 8 inches high from its lowest point. Tight and loose pulleys, 14 inches diameter, 4 1/2 inch face, wearing surfaces all scraped,—wrought iron work case-hardened. Steel wrenches, etc., are furnished complete, with the machine.

IMPROVED RADIAL DRILL.

sympathy and support of those more actively engaged in natural history studies, call forth our admiration, more especially when we consider, that in those early days of gold-seeking and local excitements of one kind and another, together with the cares of settling a family in an unbuild city; and when we find him regularly and punctually attending the weekly meetings of the Academy for so many years, we can but poorly award him the meed of praise. We might go on in words to extol his geniality, gentleness and liberality, yet we leave the records of the Academy, the objects he presented to the museum, and books he contributed to the library, to be a constant memorial of his worth to our institution.

United States, to be, if the surface indications continue below, the richest and most extensive in the world. These mines are located upon the Najalaynaga grant, and it is said that a Mr. Cassell, of San Francisco, has leased the ranch for the term of ten years, with the right to take possession of these mines, and any others that may be discovered, and work them, upon certain conditions. Unless some compromise can be effected with the present claimants, who are in possession, it looks as though a great deal of litigation will soon follow.

The Crown Point and Belcher mines consume two tons of ice per day. It is used to cool the water sufficiently for drinking purposes.

time. The rock is of very low grade. They work as low as five-dollar rock in the 16-stamp mill they have running. The Pi-Uto mill is still running on good rock, and is really a very prosperous mill and mine. The owners, the Bathen Brothers, are about to put up another battery of five-stamps, and also a saw mill, for their own use. They are "routiers." The St. John mine at this place is running along steadily, and with good results. The Long Tom is almost "played," and the mines in the immediate vicinity of Havilah are nearly or about all in the same condition. The Havilah tunnel is still being pushed ahead. Taking it all in all, there is comparatively little doing in the mines of this county at the present time."

MINING AFFAIRS IN KERN COUNTY.—A correspondent from Sageland, Kern county, under date of June 7th, writes as follows of mining matters in that county: "As near as I can learn, the Joe Walker is, or is about to be, abandoned; on account of the water on the ledge. The Big Blue, owned by the Sumner Mining Company, is working along slowly, and at present speed the big mill will not be completed for some

CORRESPONDENCE.

Kern County Mines.

EDITORS PRESS:—This camp is now laboring under a cloud, but not because the mines are not good or that they do not warrant capitalists seeking investment in this direction, but because miners show a lack of energy that is always necessary to insure success, even in the easiest worked mine—which, I, as a practical miner, believe these mines to be. The rock is of a character known as decomposed quartz and abounds in arsenical sulphide ore, which is known to be rich in gold wherever found, usually going when concentrated about 15 per cent, and valued at not less than \$200 per ton, and often much higher. Free gold has paid for all work done and a big margin besides; therefore those rich sulphurets have been entirely neglected and no attempt has been made to save a ton to ascertain their real value.

Rand has, in days gone by, made his mining property pay him the handsome sum of \$350,000, and the Howe mill and mines have paid \$150,000, and other mines have paid equally as well in proportion to the work that has been done.

I left your city on the 6th of May, to rebuild the Howe mill, and work the mines which are connected with the same, and from the discouraging reports given me, I must confess I had my misgivings as to future success, but relying wholly upon my past experience, I went to work; when I was told again that the mines were beyond a doubt good, and that there were parties only waiting to jump the mines, had there been no extension of the mining law of May 10th, 1872, to January 1st, 1875. Now, I do not doubt that there are many hundreds of disappointed sharks and drones similarly situated in the various mines of the Pacific coast. I have now rebuilt the mill and boarding-house, blacksmith shop, etc., besides putting in an entire new battery and amalgamating plates, etc. Have found in the main shaft, in the principal mine worked by Howe, a three-foot vein of ore, which will work from \$18 to \$30, about 60 feet down and not troubled with water. Also in the Blue Lode, a 2½-foot vein of \$90, where Howe extracted the most of the \$150,000 before spoken of. Also another mine within 300 feet of the mill, being a four-foot vein, which will of itself keep the mill running next year, if we may judge from appearances.

I will report to you from time to time if you desire it.

Havilah, Kern county, Cal., June 4th.

The Iowa Hill Canal.

A correspondent of the *Alta* gives the following account of the Iowa Hill canal, which opens up a large extent of mining ground: I offer no apology for sending a detailed, though somewhat lengthy account of the Iowa Hill canal, and the jubilee of the people in this section the other day, on receiving the first installment of water from it—an event duly celebrated with great enthusiasm by a salute of guns, fireworks, torch-light procession and ball.

Considering the magnitude of the work, its inevitable result and cost of construction, there can be no doubt it ranks to-day as one of the foremost works of the kind going on in the State. For many years, although vastly rich in hydraulic ground, both in extent and quality, this district has lain dormant, stagnant, impoverished from the amount of water. As year after year passed away in ruins and idleness, the hopes of the people who clung with tenacity to their property faded in proportion, until they departed almost of ever seeing it rendered profitable in their day and generation. In this dark hour a few men of very limited means, but with the courage and enterprise of the true Californian, took hold of the matter in earnest, organized a company, made a survey, and presented the scheme with such vigor that to-day a large and constant supply of water for most, if not all the year round, is no longer a problem of the future, but a fact assured. The conduct of these men, whose names I need not mention, is deserving the greatest praise. Their scheme was magnified, it is true, but of the utmost magnitude, and extremely costly. Financial difficulties, as well as physical obstacles, surrounded them on all sides. Success or ruin required each to be met in turn and conquered. If determination evinces true manhood, they were evidently the right men in the right place; for, heedless of senseless slander, evil croakings and unjust attacks, they pushed on from step to step, in a way only to be seen in California, until they made success certain. To-day they may well be proud of their exertions; long after our generation has passed away, their example will be cited by those coming after, as showing what perseverance in a good cause can do, and extolled as worthy equally of praise and imitation.

The Main Canal.

The main canal, seven feet on the bottom, four and a half feet deep, with a capacity of carrying 7,000 inches of water, was completed 25 miles last season, allowing three weeks' work more to complete certain minor points. The first large reservoir is about eight miles from town. This, now containing about 30 feet of water and covering 64 acres of ground,

will be raised this season at the wall to 50 feet in height, which will then give 43 feet of water and cover 100 acres of ground. The water in this reservoir is now available, and being used for mining purposes. From this point the main canal runs past the Forks and Secret Houses to Tadpole, New York, Sailor, Big and Long cañons, tapping each in turn, to the North Fork of the American river, making altogether a distance of 40 miles. The total cost including reservoir, will be \$500,000, of which \$95,100 have already been expended.

The Reservoirs.

To secure a constant supply of water to the capacity of the canal at least, throughout the year, the company have several excellent reservoir sites in different places; viz., one at Seilor's cañon, 25 acres; one at Big cañon, 25 acres; and several at the head of the canal, which, together, probably, will cover 500 acres more. If these reservoirs should prove insufficient for the purpose, a tunnel will be run through a gravel ridge 2,500 feet long to connect with the water of the middle fork of the American river. This district, centering, I mean, immediately around Iowa Hill, as already intimated, has only had water for years past, some three months in the season; and, yet, with miners working through short days, and under many other disadvantages, I find the hydraulic ground has paid from \$160,000 to \$200,000 per season. It is therefore safe to say that when this canal is thoroughly completed, the annual receipts of gold will reach \$1,500,000.

The Territory Covered.

Permit me, now, for the information of those at a distance, who may desire to examine this district, to glance at the territory this canal will eventually cover; a territory not speculatively rich and extensive, but proved to be both by actual development. From Bird's Flat to King's Hill, two miles below Elizabethtown, on the south side of Indian cañon, is three miles; from Smiley's store, through Iowa Hill town, to the second Sugar Loaf, on the north side of Indian cañon, is three miles; containing together, on a fair estimate, about 3,000 acres of ground, ranging from 40 to 150 feet deep, which has been proved by actual but limited washing, to be rich from the surface to the bedrock. Then there are Wisconsin and Prospect Hills; Snicker and Grizzly Flats; with other places lying intermediate of these points known to contain gold in paying quantity, all of which are now being covered by branch ditches from the main canal. Over and above all this territory already developed, there is on the line of the main canal a region containing a splendid gravel deposit, of which nothing more is known than that it carries gold strongly, and can be worked to a great advantage, stretching from Iowa Hill town ten miles to Damascus on one side, and some fourteen miles to the Forks' House on the other. Even beyond this point, to which my personal knowledge only extends, there is, it is said by those who know from personal observation, an immense field for successful hydraulic mining. Indeed, so extensive is the belt of auriferous ground intersected by this canal, it is safe to say, that if the water of the American and Yuba rivers united could be introduced, they would not together be sufficient to wash the whole in 50 years.

A New Era.

With these facts before us, it is not astonishing the people of this long deserted town, after so many years of patient endurance, should rejoice greatly in their hearts, when the first instalment of water from the new ditch came rattling into town. No wonder, indeed! To them it was the introduction of a new era—a transition from isolation and poverty to importance and lasting prosperity. Nor was there anything selfish in their joy; they knew, and felt, and said they could not as a community be thus individually blessed without their fellow-beings in all parts of the State being equally benefited; for that which enriches them is a source of national wealth. Long may that success continue and increase. Success, great success, say I, to all such undertakings, here and everywhere, the first and last results of which enrich and elevate the masses of the many.

NIGHT SIGHT VANE FOR SMALL-ARMS AND ORDNANCE.—Two English patents have recently been issued for this improvement. We quote the descriptions: 1. The first invention consists in a peculiar construction of night sight vane for rifles and other small-arms, and also applicable to ordnance, whereby when the rifle or other arm is cocked a light is produced so as to show the line of sight of the gun barrel, and thus enable the arm to be accurately pointed at night time. As soon as the arm is fired the sight vane closes and shuts out the light produced. 2. The second apparatus is intended for artillery especially. It consists of a cylindrical case containing a lamp or candle for illuminating the top of the case, which is made of glass or mica, and has a graduated arc round its circumference; the apparatus is provided with a standard and pointer, the standard having a graduated arc at the back; a shade and indicator are also provided.

NITROGLYCERINE freezes at 7 deg. or 8 deg., but dynamites well prepared maintain their plasticity at 0 deg., and even below. Once congealed the plasticity returns very slowly, but whether congealed or not they seem to be no more or no less dangerous in the one condition than in the other.

Placer Mining In Montana.

In an article on the gold mines of Beartown and Yamhill, the *New Northwest* says: Mr. Wm. Hyde returned on Wednesday from Beartown and intermediate camps. He reports heavy rain falls in Pioneer and Bear, previous to which water was never known to be scarcer at this season of the year. Lawrence & Bro. washed up \$300 last week in the lower part of Bear gulch and over \$200 the week before, which caused new ground to be taken up. Two young men, nephews of Mr. Murray, lately arrived in Bear from the lead mines of Wisconsin, have taken up claims and gone to work in the new ground which is 50 feet deep. Waterman & Cramer, just below Phelan gulch, cleaned up in one day from the winter's dump \$130; they expect to realize \$1,000 each. Several other dumps were being washed but he did not learn the result. Chinamen are ground-sluicing the lower part of Deep gulch. Joaquin Abascal is pipping a 30-foot bank at the head of Deep, but had only five hours' water a day previous to the rains. A visit to Clegg & Van Gundy's claim in Phelan gulch, found those gentlemen busy with five men and two hydraulic working down six feet of gravel on blue bedrock with good prospect. Van says he is coming to reside in Deer Lodge after the mining season is over. Messrs. Leshe & Kroeger have six reservoirs at the head of First Chance, and hydraulic diggings for 10 years to come; both gentlemen are married and happy. Grasshoppers threaten to destroy the crops in the Flint creek valley.

Mr. Hyde paid a visit to the Little Giant on Squaw Gulch which was attracting considerable attention, there being about 50 lookers on. It was working into position with a four inch nozzle and in a few days its capabilities will be tested on a 60-foot bank of gravel. Batterton's claim was also visited. They are pipping on a 40-foot bank with about 70 feet width of channel and are reported to have cleaned up \$896 in a four days' run. A new town is springing up in close proximity to the diggings called Batterton town. John Rogers was placing rocks in the lower part of his flume. Rogers & Broadbent were pipping down in a 60-foot channel, the sight of which makes the head dizzy and the perambulating visitor turns away lest he should tumble down head foremost into the abyss below. Yamhill is the best watered camp in the county as it lasts until the severe frosts about the middle of November. Board is \$6 to \$8 per week. There are more families in Pioneer and Yamhill than ever before.

Bingham Canon Mines.

In a letter to the Salt Lake Tribune a correspondent says: The mines of which we have heard so much, and which created so much excitement last year, are just commencing to open out richly. As they go down, they show an increase in value of silver, and in many of the mines the ore are found to contain gold. Take such mines as the Galena and Jordan which, without prejudice, have the largest bodies of ore exposed on the surface, and in their works, than any mine I have visited before. The Utah, American Flag, Neptune, Spanish and other mines also show large bodies of high and low grade ores, and they have thousands of tons in sight, of ore assaying from 18 to 50 ounces in silver, and 40 to 75 in lead, carrying from \$6 to \$25 in gold. But there appears to be a drawback to parties owning mines which are now in good shape; and the reason they are not more fully developed, is the fact they have not the means to prosecute the work, and are waiting for capital to come in. In my travels, though, I have seen some good mines, and prospects that would soon be mines, that are offered at very low and reasonable figures. The chances for the investment of capital here are most excellent. Although the ores are of low grade, with proper and economical management money can be made.

There are millions of tons of these ores in the mountains here that have not yet been found, and will require capital and labor. These ores differ in character—some being of either brown, yellow or gray carbonates; others galena, mixed with pyrites of iron and decomposed lead—the former predominating.

The theory of mining adopted here, generally appears to be to follow the vein of ore and run a tunnel to tap the vein in the lower works, by which method the vein is properly developed, and chutes are built and the ore wheeled out through the tunnel for shipment to the furnaces, thereby saving much expense and re-handling.

Placer mining is also carried on at present to a great extent, both in main Bingham cañon and Bear River gulch, some taking from \$8 to as high as \$25 to the man. At Bear River gulch some parties are engaged in removing the coarse gravel, and are confident of making \$25 dollars per day to the man out of the fine gravel. Quite a number of Chinamen and Mexicans are engaged in working these mines, and I am informed they are making good wages.

The big steam hammer at the Royal Arsenal at Woolwich, has a falling power of forty tons, and is driven by steam from the top. It has a striking fall of fifteen feet, three inches. The hammer is forty-five feet in height, and covers a base of about 120 feet square. Above the ground it weighs 500 tons, and the iron used in the foundation below weighs 665 tons. The hammer cost altogether about £50,000.

The Prospectors.

Man is the most restless of animals, and the miner is perhaps the least domestic of the whole tribe. Nothing and no place seems to him so good but there is a better where he is not. Mining excitements are largely due to this restlessness in men. By means of it new camps are started and new fields opened for more complete exploration. It is true many wild-cat schemes are started in this manner, run their brief race and die, but also many camps now prospering are established on a firm basis by the same means.

The miner or prospector is the true pioneer, braving all dangers and discomfort with a fortitude worthy of more praise than is generally awarded to him. He enters the wilderness, and with his pick lays the foundation, often, of other men's fortunes. It takes no small amount of courage to encounter the hardships and perils incident to the life of a true prospector, to pierce alone, or with a single companion, through the barriers to the unknown, and live in the lands heretofore given over to the red men. How rapidly are the regions marked "unexplored" disappearing from the maps, and little towns marking the sites of the Indian wigwags, while all over mountains hitherto only known by name, districts are being organized and mines opened. Arizona, until lately only heard of as the home of the Apaches, the most bloody of red murderers, and only figuring in the news columns as the scene of barbarous atrocities, is now becoming noted for its mines, and the fabulous stories of its rich gulch claims and gold ledges are exciting the curiosity and natural cupidity of the mining community. Slowly, it is true, but just as surely, the Indian is being dispossessed, and the white man is entering into his birth-right.

It is in this manner that the prospector works, not only for himself, but for all. Not only is it true that "westward the star of empire takes its way," but wherever and in whatever direction the prospector leads, civilization follows as a natural consequence. Though he may fall in the discharge of his duty, and an unmarked grave may be his only reward, still civilization sweeps on, and unknowingly hallows the resting place of the pioneer.

It is not so many years ago since the Missouri was the western boundary of the United States. The plains were the hunting grounds of the Indians, and the Rocky Mountains existed in the minds of most simply as a misty, half-hidden, fanciful picture, ranked almost as a myth. Their course was guessed at, their extent undetermined. Later even than that, Colorado, Utah and Nevada were one, and California, now one of the richest and largest of the States, was unknown. The geographers in the East, knowing sometimes even less than the least, sprinkled a few names over a vast extent of territory as a sort of seasoning, and complacently rested from their labors in their easy chairs. It was left for the prospector to do the real work, and every now and then some earnest heart and clear head, restless and energetic, would plunge into this *terra incognita*, and fighting sturdily with its difficulties and dangers, reveal some striking fact for the edification and wonderment of our easy-chair historians.

It is true that the motive he is generally actuated by is a desire for gain, not glory, but not the less is he deserving of praise, for he honestly labors for that which is often less a reward of merit in the East, than a result of favoritism.

His achievements need no historian; they speak and are continually speaking for themselves. California, almost unknown in '48, now a State immense in size and wealth, points with pride to its mines, vineyards and agriculture as the result of her pioneers, the 49ers.

Colorado can present not only her mines of gold and silver as testimony of the value of the labors of the boys of '59, the "Pike's Peak-ers," but her mountain towns, Denver, the city of the plains, her railroads and cattle ranges. And so it is throughout the West; wherever we look toward the borders of civilization we see the prospector just ahead, clearing the way with ringing blows of his axe or sturdy strokes of his pick. We seldom hear their names or (we children of a more complete civilization) see their faces, but simply know their vanguard of progress as "the Prospectors."—*Col. Mining Review*.

EXTRAORDINARY MINT WORK.—The melters and refiners' forces at the mint on the 10th, made forty-eight melts of silver ingots, which when turned over to the coiner will make 52,000 trade dollars. As the general public can have but little idea of the amount of labor involved, we may state that the greatest number ever before made in one day in the San Francisco mint was thirty-two melts. The entire amount melted and alloyed on the 10th, was \$1,444.82 ounces of standard silver and 3,345.15 ounces of gold. The necessity for this extraordinary crowding of work is partly in the great demand for trade dollars, which the capacity of the present mint is unable to supply, and also to place the metal in more convenient shape for entry in the annual settlement. In the new mint such a volume of work in a single day will probably not be of unfrequent occurrence should the necessity arise. In the present contracted melting room, however, the men working at the furnaces would be physically unable to continue such extraordinary labors for any length of time.

BIRMINGHAM makes about 1,000,000,000 steel pens annually.

SCIENTIFIC PROGRESS.

Nickel Plating.

Mr. S. P. Sharples, Massachusetts State assayer, gives a brief description of the process of nickel plating. The patent is still before the courts, and no decision has been reached in regard to it. The double sulphate of nickel and ammonium, which is the salt that is generally used, may now be had in commerce almost pure. Cast nickel plates for anodes should be obtained from the same source; the anodes should considerably exceed in size the articles to be covered with nickel. Any common form of battery may be used. The battery power must not be too strong, or the deposited nickel will be black. A strong solution of the sulphate is made and placed in any suitable vessel; a glazed stoneware pot answers very well if the articles to be covered are small. Across the top of this are placed two heavy copper wires, to one of which the articles to be covered are suspended, to the other the anode. The wire leading from the zinc of the battery must then be connected with the wire from which the articles are suspended, the other battery wire being connected with the anode. In order to prepare the articles for coating, they must be well cleaned by first scrubbing them with caustic soda or potash, to remove any grease, and then dipping them for an instant in aqua regia and afterwards washing thoroughly with water, taking care that the hand does not come in contact with any part of them. This is accomplished by fastening a flexible copper wire around them, and handling them by means of it. The wire serves afterwards to suspend them in the bath. If the articles are made of iron or steel, they must be first covered with a thin coat of copper. This is best done by the cyanide bath, which is prepared by dissolving precipitated oxide of copper in cyanide of potassium. A copper plate is used as an anode. After they are removed from the copper bath, they must be washed quickly with water and placed in the nickel bath; if allowed to dry or become tarnished, the nickel will not adhere. Great care must be used through the whole process to keep all grease, dust, or other dirt from the articles to be covered, or else the result will be unsatisfactory. The whole process is one of the most difficult that is used in the arts, it being far easier to gild, silver, or copper an article than to nickel it; but if due care be taken the result will amply pay for the trouble.

EFFECT OF PHOSPHORUS ON STEEL.—At the February meeting of the French Society of Civil Engineers, M. Euverte, director of the steel works of Terrenoire, communicated some details relative to the experiments which have been in progress for the past two years at those works, in order to ascertain the point at which the presence of phosphorus in steel becomes injurious. They were led to these experiments by the difficulties they encountered in freeing the metal from this substance. The metal containing the phosphorus was treated in a Siemens-Martin furnace, in the usual way, the charge of ferro-manganese added containing 42 per cent. of manganese. Not only in the first experiment, but in all the subsequent ones, the metal obtained was malleable and of excellent quality. Hence M. Euverte concludes that phosphorus may exist in the steel without injury, provided that the carbon be at the same time proportionately diminished. The amount of phosphorus which may be present without affecting either the tensile strength of the steel or its malleability is variable; rails of great excellence are made of steel containing 0.3 per cent. of phosphorus and 0.15 of carbon. Though not recommending the addition of phosphorus, M. Euverte believes that, for special uses, steel which contains it, provided the carbon is low, will take an important place in the arts.

THE EARTH'S TEMPERATURE.—We have always defended the idea that changes of temperature which different parts of the earth have undergone need not be explained by the hypothesis of a change in the position of the ecliptic, or the absurd notion of a change in the position of the terrestrial poles and equator, the latter being an assumption of which already Laplace proved the impossibility. Our theory has always been that a simple upheaval of say 4,300 feet (which is a trifle when compared with the earth's diameter of say 43,000,000 feet, being only its one-10,000th part) is sufficient to explain all changes in temperature, also that of the glacial period, which we hold not to have been universal, but local in different regions during different periods of time. We now see with satisfaction that Prof. Dana expresses the opinion that the Canadian water-sheet must once have been 4,500 higher than at present, and that the transformation of northern Canada into a plateau as high as Mount Washington gives a sufficient explanation for the cause of the glacial period for the eastern half of North America. Prof. Dana thinks also that when this plateau subsided, it sank below its present level, and that this was followed by a return movement.—*Manufacturer and Builder.*

The principle of dephosphorizing iron by the Jacobi process, consists in dissolving out the phosphatic impurities of the ores by treating them with sulphurous acid, the wash-water being utilized to extract therefrom the phosphate of lime.

The Magnetic Metals.

It is well known that, besides iron, there are a few other metals possessing magnetic properties, viz., nickel and cobalt in a strong degree; manganese and chromium in a feeble one. In the *Philosophical Magazine* we find a remarkable article on this subject, by Mr. W. F. Barrett, F. C. S., in which he endeavors to point out the similarity of these metals to each other, in their physical and chemical properties. Thus, as to specific gravity, that of the 38 known metals ranges from lithium 0.50 to platinum 21.5, a difference of nearly 21; whereas those of the three strongly magnetic ones are, iron, 7.8; nickel, 8.3; cobalt, 8.5, where the extreme difference is only 0.7. Their specific heat is nearly identical, their atomic one is the same, so, also, their conductivity for sound, heat and electricity. Their dilation by caloric and the amount they lengthen by mechanical strain are also identical. The enormous cohesive power of iron, nickel and cobalt in the solid state signifies these substances as the most tenacious of metals, and their melting point is only exceeded by the platinum group of metals. They are not volatile at the temperature of the hottest furnace, but only by the electric spark, when they yield very similar spectra. As to their chemical properties, the combining weight of iron is 56.0; nickel, 58.5, and cobalt the same. Chemists class these three metals in the same group from the similarity of their chemical behavior, and also the identity of their combining energy or atomicity. What has been said concerning the likeness of iron, nickel and cobalt in many respects, hold true of manganese and chromium. The former has latterly been used to replace nickel in the alloy of German silver. The compounds of all these five metals are conspicuous for the brilliancy of their colors. This uniform coincidence suggests the practical inference that nickel and cobalt might be obtained in a malleable and ductile condition when submitted to a process similar to that by which wrought iron is produced.

A Stratified Atmosphere.

We have heretofore assumed that the gases which originally composed the aerial envelop of the earth took up separate positions therein, according to their specific gravities. This might seem to be controverted by experiments on the diffusion of gases, in which those of very different weights, as chlorine and hydrogen, will intimately commingle, even against gravity, when brought into contact. This may be true in the narrow compass of a laboratory experiment, and yet not apply to any considerable thickness of the gases. Such a diffusion of one mile in depth of chlorine, would be equal to lifting up to the hydrogen a shell of solid iron two feet thick. Whether we explain the distinguishing principle of the constitution of gases as a mutual repulsion of their molecules, or, according to a late theory, as an incessant motion and clashing of atoms, there is nothing in either to warrant the supposition of the lifting or overcoming any considerable weight in the diffusion of gases. Under the first theory diffusion to a limited extent would be accounted for by the small residuum of chemical or cohesive attraction that would remain between the atoms when separated as they are in gases; and under the last theory by the mechanical impulsion of the molecules, through their hitting against each other. Evidently it is a principle which operates only within narrow limits and in the lower temperatures of the gases. The sun gives no indications of such a commingling of its gaseous elements. Spectrum analysis, when applied to its outer edges, shows first hydrogen, then the vapors of sodium and magnesium, and lastly those of calcium and iron. The same fact and order of position are found to exist in the more condensed layers of the sun spots.—*Popular Science Monthly.*

EXPANSION OF GASES.—That gases expand by heat is shown by the ascent of a hot-air balloon, and by the draught up a chimney. Since the balloon rises it must be urged upwards by a force greater than its weight. Its weight is the weight of the fabric together with the hot air in it. The upward force of the weight of the cold air which the balloon displaces, and hence the ascensional force of the balloon is the difference between the weight of the fabric together with the weight of the hot air, on the one hand, and the weight of the displaced cold air on the other. Accordingly the balloon full of hot air must be lighter than the balloon full of cold, or air must expand on being heated. Heated in a flask, provided with a vertical tube pointing downwards, the heat-expanded air forces its way out of the tube and will force down against the pressure of the air a liquid in the tube. Exposed to different temperatures such an apparatus forms an air-thermometer, but being exposed to the constantly-varying pressure of the air, cannot show exactly variations in temperature alone. If two such flasks be connected together by a tube containing a liquid, the liquid will be driven away from the flask which is most heated; and a "differential" air-thermometer is thus formed which is thus shut off from atmospheric pressure, and which is not affected by a general change of temperature, but which shows a difference in the temperature of bodies surrounding the two flasks.

CARMINE acid, according to Guignet, gives a black lake with lime, the combination formed differing in respect to color from all the other lakes formed with this substance.

MECHANICAL PROGRESS.

Cleaning Water Mains.

The following description of the means employed in cleaning out the water mains supplying the city of Brisbane, Australia, will be of interest to all who are connected with public water-works in this country. The main pipes supplying water to the city of Brisbane is 8 in. in diameter for 5 miles, and 9 in. for 2½ miles. Shortly after its completion it was found that, in consequence of the high temperature and the small quantity of mineral salts, the interior of the pipe became covered with moss, especially for the first half mile; and this, with the corrosion of the metal along the whole length, not only greatly diminished the quantity of water conveyed, but also deteriorated the quality, as portions of the incrustation became detached, and, floating down the main, caused much inconvenience to consumers, and even choked the service pipes. The scum valves, which had originally been placed at the lower points on the line of main, proved inadequate to the removal of the deposit, as it adhered to the surface of the iron, and therefore, the officer in charge of the works, suggested that it would be desirable to scour the interior of the main by the use of a machine to be propelled through by the pressure of the water. The subject being one of great importance, and involving much difficulty from the deficiency of precedents, several examinations were made of different parts of the main where it was accessible by the valves, and it was found that the incrustation was as much as 2 in. thick in parts of bottom of the pipes, and that for the whole length the metal was very rough from corrosion. The engineer having been authorized to carry out his suggestion, proceeded to construct a suitable machine for scraping the interior of the pipe, and after several experiments on different forms, completed a very efficient machine tube, which consists of a central shaft of 1 in. gas pipe 3 ft. 4 in. in length, with ferrule junction for the convenience of introduction into the openings of the main. Attached to this central shaft are a number of steel springs 1 in. wide, and 1-10th in. thick, inclined about 30 deg., so as to press on the sides of the pipe, and act both as scrapers, and to support the shaft in the center. At about equal intervals on the central shaft are fixed four pistons, each formed of a disc of India-rubber, one half in. thick, and supported in front by eight radiating plates, or flat arms, attached by hinge joints, so as to fold back on meeting any obstruction or irregularity of the internal surface of the main, any leakage of one piston under such circumstances being met by the other three, while circumference of each piston and its radiating plates also act in a very effectual manner to remove the softer deposit. For the insertion of the scraper, special castings were fitted at intervals of about one mile in the main pipe, each having a plate bolted on, and covering an aperture 2½ ft. long, and the same width as the diameter of the pipe. The object of having several openings is to afford convenient means of removing impurities, and allowing of short portions being cleaned without interfering with the supply to the city. The effect of the scraper has been very satisfactory, as it has increased the delivery of the main; while the quality of the water is so greatly improved that it is now used for manufacturing purposes, for which it was previously unfit through impurity.

NEW MARINE PROPELLER.—Probably few inventions have been more useful and simple than the screw propeller, and few have been the subject of more modifications in form, and simply in form, without any in principle, than Mr. Pettit Smith's valuable contrivance. A new propeller has been introduced by Dr. Browne, which differs considerably from any other in use, somewhat resembling when at rest the letter X, and claiming to offer many advantages over those commonly employed. These are absence of vibration, reduction of wear and tear to machinery, ready adaptability to any screw steamship, and facility of checking a ship's way with the power of driving her full speed astern in a few seconds on reversal, as well as giving considerable increase of speed and effecting a great saving of coal.

ELECTRICITY VS. THIEVES.—A novel door-fastening has been recently contrived in Berlin. It consists of electro-magnetic machinery for bolting the office doors from the manager's or cashier's desk, a knob being fastened to the desk or counter, by pressure on which the electric current is made to push a heavy bolt across the doors. The effect is instantaneous. The short period employed by a thief or forger in gaining the door, in some cases suffices for his detection; and, in that event, his escape might be effectually cut off. The machinery has been constructed to the order of a large banking firm in Berlin, in whose office it is now in use, though there has been no occasion as yet to test its powers otherwise than experimentally; but, when so tried, it has given satisfaction.

TINFOIL DECORATIVE PAINTING.—An effort is being made to introduce on a large scale in England a novel industry, well known and appreciated in Paris—that of mural decorations executed in sheets of tinfoil. The process is that of Messrs. Daniel and Co., of Paris, and it is proposed to acquire the various patents in different countries for the process.

Mammoth Cotton Press.

The new press of the Standard Compress Co., of New York, is an immense press, weight 100 tons, with 1,600 tons pressure, costing \$80,000, calculated to squeeze a bale of cotton or hay almost out of existence. The machine will press cotton or hay to any size required or desired, to 9½ inches for an ordinary bale of cotton of 500 pounds, or two ordinary bales of hay of 250 pounds each. In applying the iron ties it is almost impossible to get them tight, and the result is that the bale expands some six inches, measured at the thickest part, after withdrawal from the press. But once it expands the ties to their limit, the size is fixed not to exceed 18 inches. This press has a great advantage by reason of the uniformity in size of the bales after they are pressed. In railroad packing it has been found that a 28-foot car is entirely filled with 16,000 pounds of cotton, while its capacity for weight is 22,000 pounds. If cotton can be pressed in this way, cars will employ all their capacity when they carry cotton or hay, and be enabled to do it cheaper than now. In regard to ocean forwarding, the custom is to pack cotton as light, bulky freight. By crowding it into half the space, the carrying capacity is doubled, and the result will probably be a greater amount of such forwarding across the ocean by steam vessels, instead of the slower method of forwarding by rail. Two bales of hay, measuring in width on top of each other six feet and two inches, were unhooped and thrown together into the compress. In a moment they were hooped and taken out as one bale, and the whole mass, after expansion to the ties, measured only 20 inches at the thickest part. Cotton or hay may be thus pressed at the rate of a bale a minute, and put in such shape that a sailing vessel, instead of ballasting, may with perfect safety carry her full complement of cargo in cotton or hay.

PAPER BAGS.—Not many years ago these articles, so necessary in every description of retail business, were generally made by the consumer, and were but rarely purchased. Now the reverse is the case. They are but seldom made by the person using them, and, in consequence, a great trade is done in them, many persons being wholly employed in the business. Many patents have been taken out to produce them by machinery. They are thus made not only of the ordinary old-fashioned shape, but also with square bottoms, with rounded bottoms, with gusset-aides. They are also made in endless tubes, and cut off in lengths. Perhaps the latest invention is that of Mr. L. W. of Chatham, N. Y., and is described as "a mechanical device for making paper bags in one piece from a roll of paper." The paper is folded in the direction of its length from the two sides, so that the edges overlap one another about an inch in the center, the edges being pasted together. The paper is drawn through a folding machine, with the seam on the upper side, centrally, by a pair of rollers, which feed it along to the devices for forming the bottom of the bag. The feed-rollers then stop until the bottom is formed and the bag cut off the required length, when they again feed it forward, pushing out of the machine the bag already formed, and so on, making a bag at every revolution of the machine.

RAISING SUNKEN SHIPS.—At a meeting of the Inventors' Institute, London, a paper was read by Mr. T. Vafea, on raising sunken ships or vessels, and also prevention of foundering of same. The main features of the plan were, first closing hermetically the hatches, port-holes, and all other openings in the deck or upper or side parts of the sunken ship, and after having so closed the opening to pump down air to the bottom of the ship through tube or tubes which are inserted either through the bottom of the ship's hull, or through the ship's deck, each tube being passed down close to the bottom of the ship. The air thus introduced into the bottom of the ship rises by itself inside of the ship towards the underside of the deck, and not being able to escape presses the water contained in the ship down and out of the ship through the hole made by accident, or through holes made in the ship's bottom to allow of such escape of water. The vessel by this means will be rendered buoyant, and cause the same to rise to the surface. To prevent foundering of ships, or reduce the risk to a minimum, the ships are provided with air-tight covers, which, when fixed over the openings in the ships, confine the air therein, and keep the ship always buoyant by preventing the entrance of water.

MACHINE FOR BUILDING EARTHWORKS.—This invention consists of a strong frame, mounted on casters or wheels, for moving along the ground readily, and having an elevated platform hinged at one side, and held down at the other side upon powerful springs, on to which the earth is scraped up an ascending way, or otherwise delivered upon it. The earth is finally discharged in the direction of the place where it is to be spread by tripping the platform and allowing the springs to throw it up with sufficient force to project the earth from it. A windlass is employed for forcing the platform back for re-loading, with ratchets and pawls for holding it. The machine is more particularly designed for levee building and, it is believed, will be found very serviceable in building up banks of considerable height, by saving much of the labor of the animals in moving themselves and the scrapers up and down the banks.

was assayed a short time ago, and showed a yield of \$45 per ton in gold and silver, besides a large quantity of copper.

RICH ORE.—A large body of unusually rich ore has lately been struck, both in the Oneida and Little Amador mines.

ORIGINAL AMADOR.—*Ledger*, June 13: A very valuable discovery has been made in the Original Amador mine, at Amador city. A vein four feet in width of very rich rock has been discovered at a considerable depth below the surface east of the old works, which is pronounced to be the regular vein or ledge. This mine, some time ago sold for a high figure, but in working what was supposed to be the lead, proved to be an unprofitable investment, but the recent discovery, from all we can learn, will re-establish the good name of the mine.

CALAVERAS COUNTY.

LOYD'S MILL.—*Citizen*, June 13: This mill has been pounding away on rock hauled from the North Fork mine for the last few weeks. The rock now being crushed is taken from a new mine near McFall's ranch, and the plates indicate that it is paying well. One hundred tons will be worked for the purpose of testing the question of "pay or no pay."

SHEEP RANCH MINE.—One day this week we had a peep at the result of the last ten days' run at this mine. Placed in the sealest notched equilibrium at \$4,014 50, which is a big yield for the ten days and five stamps.

INAUGURATION OF ANOTHER NEW MINING ENTERPRISE.—*Chronicle*, June 13: Tuesday last, everything being in readiness, piping was commenced in the Emerson hydraulic claim in Happy valley. The claim was purchased by Emerson of Mr. Drumm, by whom it had been worked, on a moderate scale, for a number of years. The new proprietor has supplied the mine with all the modern appliances known in connection with hydraulics. A new flume, 720 feet in length, two feet wide, with grade of six inches to the box, has been laid. The hydraulic has a pressure of 140 feet, the water—250 inches—being conveyed to the mine in a 13-inch iron pipe. The claim is several acres in area, the gravel varying from 60 to 100 feet in depth. Everything worked first-rate when water was turned on last Tuesday.

QUAKER CITY.—Very favorable developments are being made in the old Quaker City mine, near the Junction. In running a level at the depth of 53 feet, the ledge shows from four to five feet in width, the ore being rich in free gold.

BLUE MOUNTAIN.—The Heckendorn mine is paying handsomely, and is reaching an advanced stage of development. The ore is getting richer as the shaft increases in depth. More level galleries are going to be opened immediately. The mill is running day and night.

EL DORADO COUNTY.

MINING ITEMS.—*Republican*, June 13: The active operations now inaugurated seem to make it certain that the El Dorado Water and D. G. M. Co. will construct their new ditch. A large force of surveyors have been at work on the line for several weeks, and now large numbers of Chinamen are being pushed forward to do the excavating. We do not expect the work can be completed this season; but such a beginning is being made that we are warranted in asserting that the new ditch is now a fixed fact, and the only question about it is as to the time of completion, and that can hardly exceed another year.

The so-called "Boulder Claim" has recently been sold to the California Water Company. The ground has passed into the hands of thirty Chinamen, the water company reserving all the water rights. This company has just completed and laid down about 4,000 ft. of iron pipe, to furnish a permanent supply of water to the claim. It will take about 15 years to work the claim out. Pilot Hill will now have a large, permanent supply of water, which will not only give a new impetus to mining, but will be of great benefit to the farming interest, affording a chance to raise alfalfa, fruit, etc.

HYDRAULICINO at the Excelsior is progressing very favorably; two streams, from six-inch nozzles, are kept constantly playing upon the banks of the claim. A \$20,000 or \$30,000 clean-up will soon be made.

INYO COUNTY.

MINING MATTERS.—*Independent*, June 6: A tunnel is being driven in on the Silver Sprout, which, it is expected, will tap the ledge in about 20 days, and about 50 ft. below the bottom of the deepest shaft. Captain Chase is still perseveringly hammering away, solitary and alone, as for the last three or four years, on his tunnel over at the Chryseopolis. He is now in about 150 feet, every inch of it his own labor, and full in the faith that he will strike the ledge in a very few feet more. We hope so, and a second Mono in value.

NAPA COUNTY.

THE EMMA MINE.—*Register*, June 13: We were shown some very rich specimens of rock from the Emma, a quicksilver mine in the Pine Flat district, and lying alongside the Geyer. Work was commenced two months ago, and a large quantity of ore is already out. Ten to fifteen men are employed, and it is thought that the prospects are excellent.

CINNABAR AT THE REDWOODS.—*Meers*, S. Wing, E. Nichols and J. Wilson are engaged in opening out a mine discovered some time since on the land of Mr. W., at the Redwoods, and have good prospects of making a rich find.

ANOTHER QUICKSILVER DISCOVERY.—Mr. Swartz, driver of the St. Helena and Pope valley stage, brought over on his last trip from the latter place specimens of quicksilver ore just

taken out from a newly discovered mine between Pope valley and Putah creek. The discovery was made a few days ago, and the mine is located by Messrs. Van Ardale and others. Much excitement is said to prevail.

BROTHER JONATHAN.—*Reporter*, June 13: This quicksilver mine, recently discovered by a party sent out by Dr. C. E. Davis, of St. Helena, is now being worked. A company has been formed and a tunnel is being run, and from the ore shown us, this mine presents every indication of being one of the best in that region. The mine is situated on Government land, with living water and plenty of timber in the immediate vicinity, is easy of access, and the ledge runs from Bear creek eastward over a hill 500 feet high.

NEVADA COUNTY.

NEW YORK HILL.—*Tidings*, June 13: This mine still continues to turn out the stuff of which gold bars are made. A bucket full of quartz just from the face of the work in the lower tunnel was brought to our notice which was literally, without exaggeration, filled with the yellow, precious metal. It does us more good to chronicle from time to time this steady improvement in the development of a mine which has for years lain idle, and been condemned as worked out, than the regular work of the big mine, like the Idaho, Empire, etc. Let work start up on the other end of Massachusetts hill—say in Scadden's Flat—on the Kentucky, Lukermann, or any one of a hundred, once well thought of, but now neglected or idle mine, and one by one the five hundred mines hereabouts, which are almost sure to pay sometime, would come to the front. The hills here are interlaced with a net work of gold veins and work will make them valuable.

At the Idaho mine this week all has been bustle and activity getting in the new Burleigh drills, four in number, and the air compressors to drive them. At the time we were out there they were pretty well along, and will be ready to run about Tuesday next. The large, double-acting compressor is driven by a 15-inch engine, and the whole machinery is of the best manufacture, and most approved pattern.

IMPORTANT WORK.—Some of the best hydraulic gravel mines in the State are to be found at Chimney hill, near Cherokee, in this county. They are very extensive, also; but, for want of an outlet, only 50 to 90 feet of the top ground can now be worked. A tunnel, to run from the Yuba river up under this hill, would open the same ground to a depth of three hundred feet, and also render available many thousand square yards of surface now impossible to reach. Such a tunnel has long been talked of as desirable, but capital was necessary, and has not heretofore been fit to undertake the work. We are glad to learn from the *Transcript* that the Milton Water and Mining Company recently had a survey made, and expect to begin work on such a tunnel very soon. They are said to be abundantly able to push it to completion.

OCCIDENTAL MINE.—The Nevada *Transcript* says: This mine was purchased by Bruce Lee some time in April last. It is located about three miles from town on Brush creek. The surface had been prospected a little, but no depth could be obtained on account of water. Mr. Lee erected hoisting works on it soon after its purchase, and has since been engaged in sinking on the ledge. This week he has struck the south chute of rock, and from the specimens we saw, which were numerous, it is likely to eclipse all the mines in the vicinity. The ledge is from two to four feet thick, and the rock is full of iron pyrites and galena, through which free gold is plainly visible. The depth now reached is 110 feet.

ANOTHER RICH STRIKE.—The Nevada *Transcript* seems to be kept busy in chronicling rich mining strikes, and the business, we add, is a good one. The last issue of that paper tells the following: Hamilton McCormick, who owns a hydraulic surface claim on Hitchcock ravine, at the head of Gold flat, has, by sluicing off the surface dirt, discovered a ledge, the rock of which is very rich. From 20 ounces of the rock he yesterday obtained 14 ounces of gold. The surface dirt all over the ravine below the place of discovery, has been rich, and the gold is supposed to have come from quartz, as there is no gravel higher up the hill from which it would come.

PLACER COUNTY.

MONTANA MINE.—*Placer Herald*, June 13: This mine, located in Colfax district, is now lying idle. Every indication goes to prove the mine a good one, but it wants depth, and to acquire depth requires capital.

The Rising Sun mine, at Colfax, is being worked as usual with good results. Hundreds of thousands of dollars have already been taken out of this mine, and still the commencement of its greatness is a matter of to-day. Continued developments are bringing to light better prospects, and under the management of ex-senator J. H. Neff, who has now charge of the works, we may expect to hear of bigger dividends than ever.

PLUMAS COUNTY.

MINING NOTES.—*Argus*, June 13: A large number of claims in the neighborhood of Light's cañon are being worked, and we are informed that the prospects are first-rate for a big yield. The New York and Buckeye claims, at Sawpit, are doing a big business, lately, and the miners in the lower part of the county are all making good use of the water season.

SAN BERNARDINO COUNTY.

NEW YORK DISTRICT.—*Guardian*, June 6: Mr. Rouchon came in this week from the New York district and showed us some of the richest silver ore we have seen yet. This ore is from a

new mine of his, the Clara Rouchon, and some of it was assayed a few days ago by Mr. Joseph Craig, making the return of \$1,206.71 in silver, per ton. Mr. R. reports encouragingly from that district and believes it to be the richest mining district in Southern California.

SIERRA COUNTY.

A YEAR FOR STRIKES.—*Mountain Messenger*, June 13: This seems to be a year for "strikes" in mining in this section. First the Oak Ranch Co. found a fine body of rich pay gravel; then the York Bros. commenced taking out gold in large quantities, and now Thatcher & Co. have struck it rich. The boys in the State Castle have been making a good thing, having taken out \$300 in one week. The American Hill Co.'s ground is paying exceedingly well. Alexander & Co., near Deadwood, have good diggings, recently discovered, and the Grizzly boys are taking out good pay.

GOON PAY.—The York Bros., it is said, took out sixty ounces of gold from their claim, last week, which is pretty good for a mine with only four shares. We understand they intend to drift after water leaves them, and wash the dirt when the fall rain comes.

CINNABAR.—They have got a quicksilver mine down at Brown's valley.

GETTING READY.—J. K. Code is getting a site ready for Manson's quartz mill, which he will put to work as soon as possible.

SANTA BARBARA COUNTY.

GOLD.—*Index*, June 13: Mr. Benjamin Miller, yesterday, while deepening a spring upon his place on one of the foot-hills northeast of the city, discovered gold. An old experienced miner went to the place in the afternoon, and after making satisfactory examinations declared that the prospects were flattering. This discovery has caused a good deal of excitement, and we are informed a number of persons went out this afternoon to examine the gold-bearing premises.

SONOMA COUNTY.

THE MINES OF SONOMA.—*Democrat*, June 13: The spring work on the mines in Pine flat more than fulfills the promise on their first discovery. The work of development progresses rapidly. Upon a number of claims furnaces and retorts are at work. Shipments of metal are made daily, and it is not improbable that the product of Cinnabar district will reach 600 flasks a month, within the year. A network of roads connect the mines with each other and with Pine flat. The graded road from Healdsburg up the Sonoma is fast approaching completion. This will be the best and most direct road to this great mining center. It will command their travel, freighting business and trade.

TUOLUMNE COUNTY.

THE SOULSBY MINE.—*Independent*, June 13: The rock continues to look well in the new chute at the Soulsby mine.

THE KNOX & BOYLE.—At Quartz mountain, owned by an English company, is a splendid mine. They are now down 400 ft. on a vein four ft. wide, and at the last clean-up it paid \$60 per ton.

TULLOCH & KNOWLES SILVER MINE.—Idle the intention of the owners of this lode to commence operations for its further development in about a week, or as soon as practicable.

WITH FORTUNE.—We are informed from several sources, that Thos. Myler has been favored by the fickle goddess. After many years of toil in Table mountain he has at last come upon extra good gravel—supposed, by some, to be the old "Saratoga lead."

Nevada.

WASHOE DISTRICT.

SIERRA NEVADA.—*Gold Hill News*, June 11: Daily yield 60 tons of ore, keeping the mill steadily running. The ore breasts are showing considerable improvement, and the ore crushed is yielding better than for some time past. The new engine and other machinery for hoisting and pumping one being overhauled and put in position for use as fast as the nature of the work will allow. The new hydraulic works were started up day before yesterday, and although some little delay was experienced in getting everything to work well in the beginning, all the troubles have been overcome and everything in connection is now working splendidly. The power of the water is even greater than was expected and washes the bed of cement and quartz out into the sluices almost as though it was only a bed of sand. The shipment of bullion for the month of May was \$6,391 67.

CHOLLAR-POTOM.—Daily yield, 90 tons of ore, the assay value of which is \$31 per ton. The west cross-cut from the south drift, at the fourth station level, has cut a fine, solid body of quartz over 50 feet in width, but which carries no ore of consequence as yet. The yield of bullion for the month of May was \$42,815 06.

HALE & NOBECROSS.—The 2,000-ft. station in the main incline is completed and a drift started to cross-cut and prospect the ore vein on that level. Sinking the main incline below the 2,000-ft. level for the purpose of opening still another, has been resumed, and is being vigorously prosecuted. The streaks and strata of ore found on the 1,900-ft. level are being worked and the ore extracted, and are opening out and yielding much better than was expected at the time of their discovery.

OPHIS.—The ore dumps are full, there being now about 700 tons of ore on hand, and just enough is being extracted from the ore breasts on the 1,300-ft. level to keep the supply good and the Empire State mill running. The ore now being crushed at the mill is giving much

better returns than was at first expected, the bullion being rich in gold.

ANDES.—The machinery being found inadequate for the proper working of the mine, more powerful has been purchased, and is now in progress of erection. Workmen are now engaged in grading a site for new and more extensive buildings to take the place of the present structures.

CALEDONIA.—Sinking the shaft has been progressing 3 ft. per day, the rock in the bottom working finely. Sinking the winze east of the ore vein, to connect the third and fourth station levels, is making rapid progress.

GOULD & CURRY.—Sinking the double incline below the 1,700-ft. level is making the usual good progress, the bottom in fine looking quartz, and much more favorable indications of ore developments than on the level above.

OVERMAN.—A north drift has been started from the main west drift on the 1,200-ft. level, which is making a favorable progress.

CROWN POINT.—Daily yield, 550 tons of ore, which is being extracted from the 900, 1,000, 1,200 and 1,400-ft. levels. The ore breasts on the 1000 and 1200-ft. levels are still yielding well and looking finely. The 900-ft. level shows an improvement, and the ore breasts on the 1,400-ft. level are opening out much better than anticipated, especially those of the east ledge, where the ore is of a very rich quality. The north winze from the 1,400-ft. level has made the connection with the 1,500-ft. level, giving a fine and much needed circulation of good air in that portion of the mine. The middle winze from the 1,400-ft. level is down 65 feet, the bottom still in ore of a very superior quality. The flow of water continues steady and strong from the south drift on the 1,500-ft. level, indicating that the ledge is wide and extensive on that level. The foundations for the new hoisting and incline machinery is being laid, and the machinery is being placed in position for use as fast as the durability and perfection of the work will allow. The mills are all running up to their full crushing capacity, and the future of the mine looks prosperous and lasting.

CONSOLIDATED VIRGINIA.—The ore breasts on the 1,200 and 1,300-ft. levels continue to look well and yield splendidly; the ore not only holding out finely but increasing in richness as the opening out progresses. On the 1,400-ft. level the ore breasts are opening up with a richness and extent that exceeds the utmost expectations of the most sanguine believers in the value and permanency of the development.

BELCHER.—Daily yield, 550 tons of ore, which is being extracted from the 1,000, 1,200, 1,300 and 1,400-ft. levels, the ore breasts on all of which are looking well and yielding splendidly. About 150 tons per day of the ore is being hoisted through the Yellow Jacket shaft.

IMPERIAL-EMPIRE.—Sinking the main incline is making the usual good progress, the rock in bottom working finely. The main east drift, on the 1,850-ft. level, is passing through a much more favorable formation for ore developments than has heretofore been encountered on that level.

DAYTON.—Preparations for resuming the sinking of the main shaft are about completed. Daily yield 60 tons of ore. The hullion shipment of the 1st amounted to \$88,116 66.

MINT.—Sinking the shaft is making the usual good progress, the rock in the bottom working finely. During the past week the shaft past through a very favorable streak of clay and quartz four ft. in thickness, which is supposed to be a spur of the main ledge, and which carried some ore with excellent indications of leading to something better.

SILVER HILL.—Taking out ore on the third level has been commenced. The ore on this level is of fine quality, the average assay of car samples running from \$100 to \$150 per ton.

GLOBE CONSOLIDATED.—The main north drift at the head of the incline is in 136 ft., the face still in ore. The ore stopes on this level, just being opened are looking finely. Daily yield 25 tons of ore.

UTAH.—Sinking the shaft is making good headway, the rock in the bottom blasting out finely. It is now down 82 ft. below the 400-ft. level.

SAVAGE.—Driving the main east drift for the 2,000-ft. ledge is making steady progress, with favorable indications of soon reaching the west wall.

SUCCESS.—Framing the timbers and getting ready for the erection of the new hoisting works building, is being carried forward with all the vigor possible.

WOODVILLE.—Sinking the main incline below the 400-ft. station for a pump is about completed. As soon as it is finished, drifting both north and south at the 400-ft. level will be commenced. Laying the foundations for the new engine and boilers was commenced last Monday.

SUTRO.—Driving the main west tunnel is making steady progress, the rock in the face blasting out well, with a slight increase in the flow of water, but not enough to impede or interfere with the progress of the work.

KOSUTH.—Sinking the shaft for a new level is making rapid progress.

NEVADA.—Sinking the winze on the cross lead, 200 ft. south of the main west tunnel, is making good progress, the bottom still in good ore.

DANEY.—The main west drift on the 400-ft. level is in 115 ft., the face in good working ground.

LADY BRAXAN.—Sinking the new shaft is progressing.

JUSTICE.—The erection of the new pumping and hoisting machinery is progressing rapidly.

The Russell Separator and Engine.

A few weeks since we gave the readers of the *RURAL* a description of the Improved Hoadley Engine imported and sold by Messrs. Treadwell & Co., of this city, and this week we lay before them two cuts showing the Engine and the Russell Separator mounted and ready for the field. We have not the space this week for a detailed description of the improvements on the Hoadley, and would refer those of our readers who are interested in the matter to No. 20 of the present volume of the *RURAL PRESS*. We wish, however, to again call attention to the claims of the inventor and the selling agents, who guarantee a saving of 50 per cent. in fuel and 20 per cent. in weight over engines of equal power of the old style.

The running gear and manner of mounting are of the finest character. The hind axle is bent, and instead of straining the boiler, acts as an actual support, and is attached without the use of a single bolt. The forward axle is entirely of iron, and by a novel arrangement of the bolster can be turned very short and with but a trifling amount of friction. The bolster is hollow and contains several springs, thereby materially reducing the jar on the engine when traveling over a rough road.

It seems almost superfluous to say anything commendatory of so well known a machine as the Russell Separator, which has been so long and successfully used on this coast. Of some of the later improvements, however, we wish to say a few words. The greatest of all is the "Laufenberg End Shake Shoe." By this valuable invention the capacity of the machine is very much increased, and the grain is so cleaned as to be marketable as it comes from the spout, thereby saving the farmer the trouble and expense of running it through a fan mill.

The agents inform us that from the testimony of all farmers and threshers who have used the Laufenberg End Shake Shoe these facts are proved. First—There is no jar created on the machine or separator using the End Shake. Second—There being no stakes used in putting down the separator for work, it requires but one-half the time for setting. Third—It requires less power to run the separator in consequence of there being no opposite motion or jar to overcome. Fourth—It cleans the grain better and faster, the sieves seldom if ever clogging, even in damp weather. Fifth—There is more space or room on the sieves for cleaning, consequently more capacity for the grain. Sixth—The tailings being carried by an auger evenly into the elevator, it will not clog or be overrun as in the old shoe. These facts will commend themselves to every one familiar with the requisites of a good separator, and we would recommend parties about to purchase, to see these machines at Messrs. Treadwell & Co's before doing so.

Pomona in San Francisco.

We are now enjoying the glorious succession of fruits, which the country spreads before those who hunger and thirst after the good things which Pomona dispenses. Strawberries have had, for them, a long, and of course a glorious reign. Cherries are now in full supply, exhibiting a great diversity of size, color, price, and even of flavor. Apples are common on our fruit stands, their blooming cheeks displaying a delicacy of tint which the ladies of San Francisco can hardly equal, with all their skill at painting. Green apples, for cooking purposes, are already in market, and ripe ones are announced to appear within a few days. No postponement on account of weather. Then we shall have blackberries, raspberries, peaches, pears and grapes, crowding into the city in thick profusion. But while this rich abundance of fruit is thus poured into the lap of San Francisco, how is it that her children are stinted? Families can probably purchase fruit at prices sufficiently low; but San Francisco, proper, takes its meal at the restaurant; and here it pays ten cents for about the third part of a pound of strawberries, which cost the restaurant keeper five cents a pound. Is there not something rotten in the fruit market, as well as the fruit itself, which is allowed to rot there while waiting for purchasers?

Let those who are writing essays on the healthful effects of fruit-eating, give a thought to the healthfulness of the fruit market.

SAN DIEGO MINES.—Of mining interests in San Diego the *Union* of the 3d instant contains the following: Things are moving briskly in Banner district. The new stores are being rapidly gotten ready for business. Both the Count and Frary & Schultz are laying in heavy stocks of goods to supply the demand of the rapidly growing population in the cañon. The Chariot mining company's new ten-stamp mill started up last Monday. It runs to "admiration," as the engineer says, and is doing all that was expected from it. The new mill crushes at the rate of about a ton per hour—a decided gain over the old machinery. It is running night and day. We are informed that the old "McMechan" mill, further up the cañon, is also running steadily, crushing Chariot ore.

DURING the past week about 20 tons of chrome iron ore have been unloaded daily at McNear's wharf, from Mr. Barnes' mine, near Cloverdale. There are now more than 400 tons of ore on the wharf.

The Stickeen Mines.

The following letter from the famous Stickeen mining region, was received a day or two since by James Shay, Esq., Morgan mill, Carson river, from an old friend of his. He kindly permits the *Gold Hill News* to publish it:

FORT WRANGLER, May 7th, 1874.

FRIEND JIM SHAY: I arrived here on the 4th from Victoria, and to be up to promise drop you a few notes. I came up on the "Isabel" and this letter on the same boat. About 100 miners are here that came from the mines (Cassiar) and are returning to Oregon, California and Nevada. The mines are very limited, and from what I can learn it is a terrible country to come to. There won't be anything doing in the mines for the next two months; in fact it is impossible to get there from Buckbar. Men coming from there give very bad accounts.

Lewis, arrived at Departure bay yesterday afternoon, from Stickeen and way ports, with 44 passengers. Rev. Mr. Duncan came as passenger. She arrived at Fort Wrangel on Sunday. The "California" arrived the same day. The "Hope" went alongside of the "California," loaded and started up the river. The "Glenora" had made a trip as far as the Hudson Bay post, about 70 miles below Buck's Bar, but being too heavily laden to proceed further, landed her cargo and returned to Fort Wrangel. She again loaded and proceeded on her second trip up the river, this time with a good prospect of reaching within seven miles of Buck's Bar. She had not returned when the "Otter" left, but was hourly expected.

Provisions are scarce in the mines. Those going in without grub would have to return. At the mines flour is \$1 per pound; sugar, \$1.50; beans, \$1.12½.

It is now very difficult to pack into the mines,

PORTABLE THRESHING ENGINE.

The season is very short, and the country is steep cañons and swamps—mostly mountains of rocks. If any of your friends contemplate coming up here, I am afraid that they will be disappointed. The chances will be better next season. There is a big rush now getting out of the country. Upon the whole the miners are pronounced a *bit*. I think I shall come down, for the chances are too many against me. It is impossible to get hold of any mining ground that is worth anything, and there are very few

a great deal harder than when the snow was on the ground.

There is still great dissatisfaction at the manner in which the trail is being pushed forward.

From those who left the diggings on the 4th of this month, we learn that the snow and ice had nearly disappeared, and that sluices were then running.

The general opinion is that the claims taken up last year are paying tolerably well, but that they constitute all the paying country so far

THE RUSSELL SEPARATOR.

claims that pay to work. The people in Victoria and of the steamers do all they can to keep up the excitement. I am now about chuck full of running to these big excitements.

Everything has to be packed to the mines from Buck's Bar by Indians, and they get 50 cents per pound. There are a few mules on the way to the mines, but they will not get in before the last of June, as they have to cut a trail and bridge a number of swamps. I can't advise any of my friends to come up here. A good, steady job in Nevada is worth more than a big uncertainty in this northern country. Be sure and stick to your position and let better alone. I think I shall make my way back to some part of Nevada. Provisions are cheaper here than in Victoria. I have nothing of importance to write you. I see a good many from Nevada that are on their way back. Without doubt, the next boat will take me out of this. The month of June is about the time to start for this part of the world. I believe there are some places here where the ground never thaws out. The mines are too far north to make it profitable to mine. You need not answer this, for I am undecided, but in all probability shall go south on the next boat. Respectfully yours,

C. A. TURNER.

The *Nanaimo Free Press* of May 23d has the following particulars from this country: The H. B. Co.'s steamer "Otter," Capt.

discovered. Thibert creek has been prospected and with very unsatisfactory results. The new creeks, Delore and Cañon, they say nothing has been found in them.

The country is not a gravel country, and the report about the hill or bench diggings is without foundation.

The water is now rising and the best of the season will soon be over, as the water rises too high to allow the claims to be worked.

They say that they believe there is gold in the country, but that it is very spotted and extremely difficult to find, and that the country is very rough and the season short. They report that those who are working are running in debt for grub; in fact their report of the country is very discouraging, but such has been the history of all gold excitements, a great rush and then the reaction.

It is highly probable that the Cassiar gold-bearing country is very spotted, and the paying ground is not of any great extent, but this season's prospecting may open up new creeks that will yield the precious ore more readily than any of those at present known.

From what we can learn there is a large number who will return, as they are not in a position to stay in the country, unless paying diggings are struck.

The Con. Virginia yielded \$416,000 in May.

The K K Mine.

In an article on mining matters last week, the *Eureka Sentinel* speaks as follows of the K K: We stated last Sunday morning that the mine had opened out finely wherever worked upon, exposing large masses of high grade ores in its slopes, breasts and raises. These items of intelligence we gather from its courteous superintendant, Mr. Keyes; but to-day we write from personal knowledge and can therefore largely discount whatever we then said of it. The mine has very considerably improved in appearance since our last report of it was issued, and each succeeding day will but add to its value and permanency. Of this we are now thoroughly convinced, and the predictions we have heretofore made concerning its resources will ultimately become established facts.

The ore body which has been developed in the vicinity of the winze at the extreme northeastern end of the workings on the second level has opened out in all directions since we last saw it. The lateral and longitudinal dimensions are at present unascertainable, for the ore limits have not been as yet reached, nor are there the least indications that they soon will be, either. From the northeastern chamber, which shows finely in ore, two cross drifts were commenced at the period of our last visit, one running east and the other west. The latter has since then been pushed 150 feet ahead through solid ore of a very "fine" quality—top, bottom, sides and breasts all showing well in it. The former, facing east, has not as yet made much headway, nor will it for a while either, though it has been driven through ore the whole distance. These two drifts have thus far penetrated ore a lineal extent, east and west, of 65 feet. Stopping or raising has been also very vigorously pushed forward and upward, southwestwards towards the Marcelina east incline, with which a junction will soon be effected. When this is accomplished, which will be in a few days more, a current of pure fresh air will then fan the cheeks of the grateful miners, whom it will freshen and invigorate, as it does all who labor below the surface of terra firma.

The raise, which is a large one, has already been driven over 60 feet from the winze chamber mentioned above, and its whole distance thus far is in ore to which there appears to be no visible limit. Six sets of timber, eight feet apart, perpendicularly and laterally, have been lately placed in position without the apex of the ore body being yet reached. The depth of the ore from the level of the chamber is at present indicated by the 65 feet which the winze has attained, ore being visible the whole distance. Operations have also been hurried forward on the third level. For we found the northeast drift in on its course about 250 feet from the shaft to where it is expected it will intersect the winze run from the upper level. It is about 100 feet as yet from its objective point, and the ground through which it is being driven is soft and easily worked, and is besides very favorable for ore being soon found to the eastward of its course. About midway in this drift a crosscut has already been advanced 50 feet to the northwest, disclosing patches of ore and lumps of galena at its farthest extremity. We are of the opinion that ere we make another visit to this locality ore will have been developed in good quantities. The ore bodies in the immediate vicinage of the shaft are looking and yielding admirably, 45 tons per diem being shipped per teams to the Hoosier furnace for reduction.

The recent strike in the neighborhood of Cunningham shaft, Marcelina West, is also looking and doing well. A large amount of superior ore has been taken, within the past two weeks, from the breastings hereabouts. We must admit that we have never before seen this fine property in a better condition than it is at the present writing; and we can also say that we believe it to be eminently worthy of the truest confidence of the public. About 50 men are employed in the mine.

AGASSIZ' SUCCESSOR.—The London correspondent of the *Cincinnati Commercial* says he heard an "eminent man of science" in that city, an intimate friend of Huxley, remark that Harvard College couldn't find any living man except Huxley, capable of carrying on the work from the point where Agassiz had left it. When asked if he thought Huxley would refuse the offer, the same gentleman responded: "I'm not so sure of that. It doesn't make much difference with such a man as that from what spot on the earth he speaks—the world will hear him. They would have to make it worth his while—I mean in money; for to him money means the furtherance of knowledge and the increase of opportunity. It would not be very difficult for the Americans to supply him with larger means for the accomplishment of his aim than England does, and if so I believe he would go."

MINING INTELLIGENCE.—The work of hydraulic mining the surface of Cedar hill will be prosecuted vigorously. The pipe, which was damaged by a heavy pressure of water, will be repaired so that working operations can be resumed to-morrow. The water, which has already been turned upon the hill, has unearthed a number of bowlders, which when broken were found to be lousy with gold.—*Gold Hill News*.

Work has been suspended in the North Star mine, Nevada county. It is understood that a change of management is soon to be made.

USEFUL INFORMATION.

Gun-Cotton.

Gun-cotton is produced by steeping cotton fibre in a mixture of nitric acid and oil of vitriol. The cotton does not sustain any change in appearance by this treatment, but it increases considerably in weight. The cotton, in fact, parts with a quantity of water, and absorbs in its stead the elements of the nitric acid, which are much heavier than the water displaced. In this way the cotton is impregnated with a large amount of oxygen, which is thus ready, on the application of heat, to form gaseous compounds with the carbon of the cotton.

When this explosive substance is made according to the Abel process, it possesses three characteristics which render it peculiarly adapted to military engineering operations. It can be stored and transported in the wet condition—that is, saturated with moisture—in which state it is absolutely non-inflammable. While in this wet state it will explode with terrific violence if a small portion of dry gun-cotton be detonated in contact with it. Lastly, it may freely be brought under fire without fear of accidental explosion.

One of the characteristics of gun-cotton which contributes to its applicability to military purposes is that it may be freely brought under fire without fear of accidental explosion; that is to say, a package of compressed gun-cotton would not explode if struck by a rifle-bullet. If the gun-cotton were dry, the heat caused by the impact of the bullet would set it on fire, and it would then merely burn away with more or less fierceness, according to the amount of gun-cotton in the package. But if the gun-cotton were damp, the impact of the bullet would have no more effect than it would have on wood, earth, or any like inert substance. In the case of nitro-glycerine compounds, however, exposure to musketry-fire would be attended by far more serious results. Under these circumstances, and at all ordinary infantry ranges, a package of dynamite or lithofracteur will explode with considerable violence.—*London Times*.

VENTRILLOQUISM EASILY LEARNED.—According to a writer in the *Chicago Advocate*, the ventriloquist's art is as easily learned as falling off a log. He maintains that there is no difficulty in acquiring the power. In the first place, he says, speak any word or sentence in your own natural tone, then open your mouth and fix your jaws fast, as though trying to hinder any one from opening them further or shutting them, draw the tongue back in a ball, speak the same word, and the sound, instead of being formed in the mouth, will be formed in the pharynx. Great attention must be paid to forming the jaws rigid. The sound will then be found to imitate a voice from the other side of the door when it is closed, or under a floor, or through a wall. To imitate a sound behind a door partly open, the voice must not be altered from the original note or pitch, but be made in another part of the mouth. This is done by closing the lips tight, and drawing one corner of the mouth downwards or towards the ear. Then let the lips open at that corner only, the other part to remain closed. Next breathe, as it were, the words out of the orifice formed. Do not speak the words distinctly, but expel the breath in short puffs at each word, and as loud as possible. By so doing you produce the illusion in the minds of your listeners that they hear the same voice which they heard when the door was closed, but more distinctly and nearer on account of the door being open. The lips must always be used when the ventriloquist wishes it to appear that the sound comes through an obstacle, but from some one close at hand.

BLEACHING SHELLAC.—Shellac may be bleached by dissolving it in boiling caustic potash lye, filtering, and then passing chlorine gas through it till the gum is entirely precipitated. The precipitate should be well washed with hot water. While soft it may be modeled into sticks, which, when thrown into cold water, will harden. Varnishes made with gum thus purified should not be used on cabinet work inlaid with brass, as it acts chemically upon brass. Shellac may also be bleached by dissolving it in 85 per cent. alcohol, in the ordinary manner, making the solution rather thin, and then adding animal charcoal, until the whole forms a thin paste. It should then be exposed to the sun for a fortnight, or longer, if, when a small sample is filtered, the solution is not of a light yellowish brown color, and does not give a fine clean polish on light-colored woods. If, however, it is found to be sufficiently bleached by such a trial, the whole may be filtered. A second treatment of the charcoal with alcohol will recover more of the gum, a portion of which will of course be wasted in the process. If the operation be well performed and the solution be used sufficiently thin, its color will be so slight as not to perceptibly stain the lightest colored woods.—*Artisan*.

PLASTER-OF-PARIS for picture frames is mixed up with weak alum water, or a solution of one ounce of gum-arabic to the pint of water. It is applied as usual, and moulded when soft. When dry, it has a hard and smooth surface, ready for bronzing.

TALLOW may be bleached by prolonged exposure to sun or daylight. This is in fact the way in which tallow candle manufacturers bleach and improve their freshly made and very yellow looking candles.

Nothing Like Leather.

There are people who think that leather is used for boots, shoes and gloves only, others better informed, know that it is also used for harness, carriages tops, helms, velises and trunks, but then their information about it is very stop. We can inform the latter, that at present, leather jewelry is manufactured on a large scale in Vienna, also leather flowers and fruits, as clusters of grapes, etc., embellished picture frames, brackets, work-boxes, also Paris fancy articles and bijouterie.

The people of Northern Europe, as Russia and Sweden, use leather as the chief material for clothing, while leather tapestry, a century ago so much in vogue, is getting in the fashion again. For furniture coverings it is much better than rush, velvet plush or silk, as it does not wear out. The Hessian soldiers during the 30 years' war, wore cuirasses of leather, while the French gunboat *Provence*, used during the Crimean war, was plated with leather, but it was found rather expensive. The natives of the Arctic Regions, navigate in leather canoes, while our Patent Office can boast of a dozen expired patents for portable leather boats. There is a leather gun in the arsenal of Copenhagen, Denmark, left from a battery of 12, which Charles XII. brought from Sweden, to attack Copenhagen. It consists of a smooth light steel tube, many times tightly wound round spirally with tough leather straps two inches wide, the whole wound with a single piece of smooth leather, giving it at a distance the appearance of an old bronze piece; this gun weighs less than one-third of ordinary guns, and the battery was intended to cross the ice, and well adapted for that purpose, being literally and really a light artillery.—*Manufacturer and Builder*.

HOW TO REPAIR LEAKY ROOFS.—Melt together in an iron pot, two parts by weight, of common pitch and one part of gutta-percha. This forms a homogeneous fluid much more manageable than gutta-percha alone. To repair gutters, roofs or other surfaces, carefully clean out of the cracks all earthy matters, slightly warm the edges with a plumber's soldering iron, then pour the cement in a fluid state while hot, finishing up by going over the cement with a moderately hot iron, so as to make a good connection and a smooth joint. The above will repair zinc, lead, or iron, and is a good cement for aquariums.

FIXING SLATES.—Slates, instead of being nailed to the roof, may be fastened by movable hooks, about two inches long, which are soldered to conically formed zinc plates, four to six inches long. The slates are thus kept securely between the hook and zinc plate, and can be removed simply, with the greatest facility, by turning the hook. Thus one or more of the plates can be taken out for repair, or new ones inserted, without interfering with the rest. The method is said to make a roof watertight.—*Scientific American*.

SUBSTITUTE FOR BRISTLES.—The fibrous bark of the sugar palm (*arenga saccharina*) proves to be a good substitute for bristles and animal and human hair. The treatment is simple. The bark is first immersed in water and boiled for some time in an alkaline solution; the fibers are then soaked in an emulsion of fat, alkali and water for about 12 hours, after which time they are sufficiently hard and elastic for the above named use.

TO RENDEW WOVEN FABRICS NON-INFLAMMABLE.—M. Patena proposes, instead of sodic tungstate, a mixture of four parts borax with three parts magnesic sulphate. One hundred grammes of the mixtures are to be dissolved in 300 to 400 cubic centimetres of water, and in this solution the fabrics are placed until soaked, then wrung out, dried, and ironed. Another mixture proposed for the purpose is that of ammoniac sulphate and gypsum.

A REDDISH BROWN PAINT FOR WOOD.—The wood is first washed with a solution of 1 lb. cupric sulphate in 1 gallon of water, and then with ½ lb. potassium ferrocyanide dissolved in 1 gallon of water. The resulting brown cupric ferrocyanide withstands the weather, and is not attacked by insects. It may be covered, if desired, with a coat of linseed oil varnish.

It has been discovered that a small cylindrical point of steel when made to rotate upon glass in such a manner that its longitudinal axis shall make an angle of 45 deg. with the surface of the glass, approaches in effect so nearly to that of the real diamond, that it is a very cheap and effective substitute as a glass-cutter.

FOR BURNS—BEST AND QUICKEST.—Oil, if you have it,—linseed, almond, olive, or any other—linseed is best. Pour it over, then sprinkle a thick coating of flour; then lay over a coat of cotton-battling, or wadding. If you have no oil at hand, apply the flour at once without it.

PROF. HIRZEL, of Leipsic, recommends as a lute for covering the corke of vessels containing volatile substances, as benzole, light petroleum, etc., a mixture of finely ground litharge and concentrated glycerine. Common glycerine, if concentrated, will answer the purpose.

It is a well-known fact that gum-arabic will not cause some kinds of blotting-paper to adhere. This may be remedied by adding to eight ounces of the concentrated solution, sixteen grains of aluminum sulphate. Alum answers also, but not as well.

MISCELLANEOUS.

Improvements on the Comstock.

In the remarks accompanying the last weekly mining review of the *Virginia Enterprise*, that paper says: "The work of opening and developing mines along and in the neighborhood of the Comstock range, however, is being prosecuted with unusual and almost daily increasing activity. Machinery is constantly arriving from California for mines both great and small, and is being put in operation as rapidly as possible. The feeling prevailing among our mining men is excellent, and shows that there exists among them the utmost confidence, in the great mineral belt which is now being mined and explored. Those engaged in the development of mines seem only anxious to push forward the work upon which they are employed, having faith to believe that sooner or later they will find deposits of ore that will richly reward their labors and amply compensate them for all their outlays. The number of new and costly hoisting works that are now going up is astonishing. They are almost as numerous as were common windlasses and whims in the early days of Washoe. Good work, too, is being done wherever mining operations are being carried on. Aided by giant powder, nitro-glycerine and other new powerful explosives, and by tools the finest in the world, with Burleigh drills and other machinery never before brought to bear in our mines, our miners now make twice as rapid progress in all mining operations as they did in the early days.

A large three-compartment shaft, fully and substantially timbered, is now sunk to the depth of 800 or 1,000 feet in about the same time that was formerly occupied in sinking a common round hole to the depth of 300 to 400 feet. Tunneling and drifting are also pushed forward twice as rapidly as in former times, and we hear much less said about hard rock than some years since. In the early days rock was occasionally encountered in shafts and tunnels, which for weeks came near checking all progress. Now, however, with nitro-glycerine and giant powder, our miners crash through these flinty strata in a very short time, and at a tenth part of the former cost. With our new and powerful explosives it is not necessary to bore into the rock to be blasted the huge holes that were required when the common black powder was used. Then a great hole was necessary, as a great quantity of explosive used had to be introduced to produce the desired effect; whereas, with the explosives at present in use, small, keen drills, may be used and a hole of sufficient size may soon be made to accommodate the quantity of giant powder or nitro-glycerine that is required to do the work. Thus it will be seen that we have taken a new departure in all mining operations, and to this new departure is doubtless owing, in no small degree, the remarkable activity observable throughout the country in all manner of prospecting operations.

ANTELOPE DISTRICT.—From a party who has recently been in this district, which is situated some forty miles north of Eureka, we learn that the mines generally are looking as well as could be desired. The names of the principal lodes are the Monitor, Evening Star and Kearsarge—three parallel locations. Work is being prosecuted on the Kearsarge, and the ore extracted assays \$234, and is abundant in quantity. The vein is six feet wide, with smooth, well-defined casings, its pitch being to the east at an angle of 45 degs. On the dump there are 100 tons of good ore, taken out in sinking fifty feet. The evening Star opened 160 feet down; the lode at that point being six feet wide—the grade of ore being estimated as good for \$70 per ton, actual haulion yield. On the Monitor a fifty-foot incline has been opened, its inclination being slightly towards the west. This vein is also six feet in width, and its grade of ore about \$60; there being 100 tons on the dump. The district is profusely supplied with heavy timber, and about half a mile from the mines there is sufficient water for a twenty-stamp mill. It is believed that wood can be delivered at the mill for \$3½ per cord. The district was discovered and brought into prominence by Daniel McMurphy, a pioneer of Gold Hill—in 1859—and White Pine in 1868. It is to be hoped he will make a fortune out of the property, which, according to all accounts, is of great value.—*Eureka Sentinel*.

OREANA SMELTING WORKS.—The Oreana smelting works, built originally for smelting ores from the Montezuma mine, and run for some time by an Eastern company, when charcoal was worth 60 cents a bushel, will shortly be in full blast again. The works are now owned by Gen. P. E. Connor, who intends to run them on ores from Utah, with sufficient of the Arabia ores for a flux. Several car loads of coal and wood have arrived on the ground, and the works will start on or about the 15th instant.

The *Marin Journal*, of June 5th, states that operations on the North Pacific Coast Railroad are being actively commenced this week. A gang of 400 men is to leave the city by ocean steamer this morning for Tomales, to commence the work of grading at that end, coming this way. During the week a similar force will strike in at the paper mill, and work down the bay, and other gangs will set in along the line. Mr. Buchanan will also start the work on the trestles, between here and Saucelito, employing large forces, and spanning the several gaps with the greatest possible expedition.

Pioche Mines.

The *Pioche Record*, of the 7th, has the following to say about mining matters in that camp: Mining matters, during the past week, have, if possible, been duller than the week preceding. The situation in the leading mines in this region is almost without any change. In the Raymond & Ely quite a small force is at work. They are engaged in opening the east and west drifts on the 11th level, in which fair progress has been made during the week. The face on either side does not look more encouraging than at the period of the last report. For the past few days no ore has been taken out or shipped, and the mills will be occupied on tailings, of which there is an enormous quantity on hand, and appear to pay every time they are worked.

At the Meadow Valley, the crosscut from the lowest station of No. 3 shaft has cut the ledge, on which a drift is being opened in a westerly direction towards the Raymond & Ely ground. The easterly drift has also been commenced. In the levels above there is little change to report. The connection with the ninth and the drift from No. 5 shaft has not been made, but must be close at hand. Ore is still being taken from the western stopes above the ninth level, and on the east above the 625-foot level. The work of sinking shaft No. 5 is going on as usual, and also the drift to connect with the ninth level of No. 3. At the mill at Dry valley matters are without change.

At the Pioche, the connection between the new shaft and the old works has not been effected. Parties of workmen are engaged on both sides, and it is expected that an opening will be made in but a very few days. The drift running southerly from the bottom of the shaft is now 130 feet in length, and is being prosecuted as rapidly as circumstances permit. The old workings and dumps are being carefully cleaned up by men working on shares, and are a source of profit both to the company and the men.

The Washington & Creole presents no new features. The sinking of the Mazepa shaft is being urged forward as speedily as possible, and is the principal operation now going on in the mine. The main drift is being opened easterly towards the shaft, and the work of sinking the middle winz is still continued. During the week the Floral mill recommenced work on ore from this mine, and we are informed will continue until the ore that has been brought to the surface is reduced. The pulp assays are satisfactory, so far.

Much activity still prevails at the American Flag, and some considerable quantity of ore is being taken from the upper stopes and reduced at the mill. The shaft is being sunk with all convenient speed.

The Newark mine is supplying the mill of that company with considerable ore, with which and some custom rock the mill is kept constantly at work. In the old works of the mine the lower level is being opened out, and above that from the upper stopes from four to six tons of ore are raised daily. The work on the new shaft is progressing satisfactorily. This company last week shipped bullion to an amount of something over \$6,000.

The Portland, Chief of the Hill, Bowery, Havana and other mines this week are in a condition so similar to that of last that they do not call for any more extended remark.

Last week we observed that some teams were engaged in hauling rock from the Silver Peak to the Floral mill. The ore looked of good quality, and we are informed that quite a quantity of it has been found in the lower levels of the mine.

The total shipments of bullion for the past week, per Wells, Fargo & Co., amount to \$28,591.

A SAN DIEGO MINE.—There has been received at the office of the Chariot Mill and Mining Company, for a 12 days' run of Pioneer mill, \$5,002.64, being the proceeds of 108 tons of ore crushed. From this date shipments will also be made from the company's new mill, which has a capacity of 20 tons per day, averaging \$45 per ton. The prospect for this mine, which has been making improvements in opening lower levels, building new mills, etc., is of the most flattering character, and were the mine located in the Comstock lode, would-to-day sell for 500 per cent. more than present price.

SURFACE MINING AT SILVER.—The different parties working gravel claims in the vicinity of Silver City are meeting with good success. Matthews & Co., who are working a claim in Nigger gulch, a short distance west of the town, are making from \$15 to \$20 per day to the man. Messrs. Jones & Cook, who are working another claim situated northeast of the town, are also making wages.

The dry leaves of the beech yield 20.8 parts of extract to boiling water, and this gives 2.44 parts of ash, which contains a sensible quantity of manganese. It is suggested by Wanklyn that an examination of the ashes of leaves might lead to the discovery of a new element, or at least that many might be found to contain cesium and rubidium.

HAMILTON McCORMICK, who owns a hydraulic surface claim on Hitchcock ravine, at the head of Gold flat, Nevada Co., has, by sluicing off the surface dirt, discovered a ledge, the rock of which is very rich. The ledge has been stripped for about 100 feet, and gold is plainly visible all over the surface. From 20 ounces of rock he obtained 14 ounces of gold.

TABLE OF CONTENTS.

GENERAL EDITORIALS.—Academy of Sciences: Improved Radial Drill, 385. The Mining Laws: Sticken Mines: San Diego Mines: An Important Invention for Quartz Mills: Scientific Lectures and License, 392. Improved Method of Observing Altitudes of the Sun at Sea: Working Claims by Tunnels, 393. General News: Patents and Inventions, 396.

ILLUSTRATIONS.—Improved Radial Drill, 385. Portable Threshing Engine: The Russell Separator, 390. Improved Instrument for Observing Solar Altitudes, 393.

CORRESPONDENCE.—Kern County Mines, 388.

SCIENTIFIC PROGRESS.—Nickel Plating: Effect of Phosphorus on Steel: The Earth's Temperature: The Magnetic Metals: A Stratified Atmosphere: Expansion of Gases, 387.

MECHANICAL PROGRESS.—Cleaning Water Mains: New Marine Propeller: Electricity vs. Thieves: Tinoli Decorative Painting: Mammoth Cotton Press: Paper Bags: Raising Sunken Ships: Machine for Building Earthworks, 387.

MINING STOCK MARKET.—Table of Daily Sales and Prices and Comparative Prices for the Week: Notices of Assessments: Meetings and Dividends: Review of Stock Market for the Week, 388.

MINING SUMMARY.—From various counties in California and Nevada, 388-9.

USEFUL INFORMATION.—Gun-Cotton: Ventri-Logism Easily Learned: Bleaching Shells: Nothing Like Leather: How to Repair Leaky Roofs: Fixing Slaters: Substitute for Bristles: To Render Woven Fabrics Non-Inflammable: A Reddish Brown Paint for Wood: For Burns—Best and Quickest, 391.

MISCELLANEOUS.—The Iowa Hill Canal: Night Sight Vane for Small-arm and Ordnance: Placer Mining in Montana: Bingham Canon Mines: The Prospectors: Extraordinary Mint Work, 286. Pomona in San Francisco: San Diego Mines: The Sticken Mines: The K. K. Mine: Agassiz's Successor: Mining Intelligence, 390. Gold and Silver on the Pacific Coast: Trustees and Stockholders: The Hungarian Hill Claim: Survey: How the Pulse of the State Beats, 394.

RICH STRIKE.—A strike has been made in the Prussian South mine, Jefferson canon, which has caused some excitement in Belmont, Nev. The *Courier* says that in the incline shaft, at the depth of 180 feet, a body of ore was struck that excels in richness anything ever before encountered in any mine in the State. A small quantity of ore was sent over from the mine to this place, an assay of which was made by Semmel Mcmasters, superintendent of the Monitor-Belmont mine, that yielded at the rate of \$20,307 86 per ton. At this rate of yield the ore is considerably more than one-half silver.

SOME new mines have been discovered between the head of the Columbia lake and the bend of the Columbia, and attracting a good deal of attention. As yet there is not much known of either their extent or richness, but it is believed they will prove to be good paying diggings. They are situated in British Columbia, and are three or four hundred miles from Walla Walla.

A VERY valuable discovery has been recently made in the original Amador mine, at Amador city. A vein four feet in width, of very rich rock, has been discovered at a considerable depth below the surface east of the old works, which is pronounced to be the regular vein or ledge.

CLAY STREET RAILROAD.—Two dummies have been added to the plant of the Clay Street Hill Railroad. They are of commodious construction, with the seats at right angles to the track, and each will afford seats for from twenty-five to thirty passengers.

The Kohler Reduction works to be erected at Damon's Landing, near San Leandro, will cost about \$150,000, of which about \$30,000 has been expended. About three hundred men will be employed. The company proposes to purchase ores on its own account.

SMELTING operations are to be inaugurated in White Pine, Nevada. One thousand tons of rock have already been engaged to commence with.

FLATTERING accounts are received at Los Angeles on the recent discovery of gold in mountains to the north of that city.

The Mining Laws.

The new Bill, introduced by Pratt, providing for the compulsory patenting of all mining claims which had produced as much as \$5,000, has been indefinitely postponed by the Senate Committee on Public Lands, to which it was referred. The vote for indefinite postponement stood: Ayes—Windom, Kelly, Oglesby, Bontwell and Stewart. Noes—Sprague, Tipton, Hervey and Pratt. It seems hardly probable that either this or the Negley amendment will pass, over the adverse reports of the committee.

The Committee on Mines and Mining have as yet taken no action on the Ward Mining Bill.

A circular is being prepared at the General Land Office, containing instructions to the Register and Receiver, with reference to the Act recently passed, extending the time for making the first expenditure on mining claims. The circular says, by this legislation the requirements of the fifth section of the Mining Act of May 10th, 1872, and the amendatory Act of March 1st, 1873, are changed, by extending the time for the first annual expenditure upon claims located prior to May 10th, 1872, to the first day of January, 1875. The requirements in regard to expenditure upon claims located since May 10th, 1872, are in no way changed by the above amendatory Act.

Of course the miners have understood that the extension of time applied only to claims located prior to May 10th, 1872, and it was explicitly stated in the amendment, which we have published several times. Claims located since the passage of the Act, were compelled to make the annual expenditure of \$100 or be liable to re-location. Complaints come from Napa county that snits have already been commenced in the Sonoma District Court in consequence of the passage of this statute, involving the title to seven of the new cinnamon mines in that region. The *Register* says that parties who equated on the mines thirteen years ago but did not work them, now put in a claim after the present owners have expended a considerable sum in their development. This is the first complaint against the amendment that we have heard; but it is hardly probable that the law will permit the abuse mentioned above. If these mines were virtually abandoned and then taken up by other parties and worked for some time, without molestation by the original locators, until they became valuable, it is of course proper that the parties making the developments should have the mines. In most mining districts there are laws as to the time a mine can lie idle without being open to re-location, and the law of Congress recognizes these miners' regulations; but as it is only lately that Pine Flat has become a mining section, there was probably no local regulation on the subject. The question will shortly be decided by the Courts.

Sticken Mines.

No authentic contradictions have been made to this discouraging reports from the Sticken mines. Some advices from that part of the country state that there is very little gold but plenty of coal; others again say that there is plenty of gold, but the weather interferes with working the claims. Some few miners have made money, but by far the larger portion of the would-be-millionaires will return with a smaller stock of money and a larger stock of experience. No news of importance has recently come from the mines, although report says the California company have washed up over \$3,000 in four days, and that the Moore company are doing well on Tibbet creek. Freight from Fort Wrangle to Buck's Bar is \$80 per ton, while the passage money is \$25.

One correspondent from these mines states that as far as he sees there has not been a hole sunk in the channel of the creek, although it is shallow and can be worked by wing dams. He says that there are about 5,000 inches of water and any amount of ice. There are no bars in the creek, and only about two miles of it that looks well. He says that a great many men are going away from the mines, and that little work can be done there before August. This correspondent concludes his letter as follows: Things are looking blue, but I will try and etch her out till fall and see how things will end. I don't consider men going back now know anything about it. There may be something struck this summer. There is very little said about Tibbet's creek. I have not been there. Claims there are not selling for anything; they are deep. The truth is it is impossible to prospect in this country at this season of the year. What little provisions there are for sale here, and they are mighty scarce, are a dollar a pound; sugar is worth two dollars.

The Victoria *Colonist* of the 9th contains the following information from the mines: Provisions at Buck's Bar were cheap, but in the mines they were getting scarce, though flour was still sold at \$1 per pound. The health of the miners was good, but at Fort Wrangle there had been some sickness, owing probably to the bad water there. The general opinion was that the mines were rich, but no new discoveries had been made. There were about 600 men actually at the mines, about 300 on the road, and about 50 at Fort Wrangle.

San Diego Mines.

The principal mines of San Diego county are in Julian and Banner districts, which adjoin each other, in the mountains about 60 miles inland from the town of San Diego. These mines were first discovered in 1870, and for a time attracted some attention. But the popular prejudice against mining in the southern part of the State, and the cloud thrown on the title of the property by a neighboring Spanish grant, together with want of capital, have prevented these districts from being very prosperous. Several hundred men, however, have been working and prospecting in that part of the country since the first discovery, and a few of the mines promise to be permanent paying institutions.

When the first mine was discovered—the Washington—in Julian district, the ore was very rich; and as several other promising veins were soon struck, Julian bid fair to be a prosperous camp. As is usually the case, but few of the claims proved to be worth much, and these few have been worked at intervals ever since. Time has demonstrated, however, that with few exceptions the rich ore run in chimneys, and that these once worked out, the remainder of the ore was of a much lower grade. In fact, at present there are, perhaps, not more than half a dozen of the original discoveries made in Julian district being worked at a profit to any extent.

About seven or eight months after the discoveries of Julian, a rich ledge was accidentally found in San Felipe canon, by parties hunting for wild grapes. This canon is only a mile or two from Julian City. Immediately after this discovery a number of others were made, some of them being exceedingly rich. The canon was soon filled with busy miners and prospectors; cabins were built, claims staked out, and a number of arrastras were set running. The ledge was situated up on the side of the canon, and the ore was selected and carried down to the creek in the canon; was there burnt, slaked, and put through the arrastras. Some of these claims paid three ounces handsomely by this method, and "feet" in the canon were above par.

A new district was laid out and called Banner; and a Wilson steam stamp mill, formerly at Julian, was brought down to the canon end set up there. Shortly after the Antelope Company put up a fine five-stamp mill, and George McKean built a wooden five-stamp mill to work rock from his mine. Some of the arrastras were abandoned, and the rock crushed at the mill. After this was done the miners expected greatly increased returns, but in this they were disappointed. It was found that many of the richest claims, the Antelope, Madden, Kentuck, Chaparral, City of Richmond and others, were mere pockets, and that while the rock was selected and crushed in arrastras it paid well enough; but when not sorted and milled, it fell below expectations. Several of the mines that were richest then are not worked now. The Redman claim, once the richest in the canon, and the first discovered there, did not turn out as well as was expected. Mismanagement, or want of knowledge of the business, prevented the owners from realizing much from it, although a capitalist from this city took it in hand.

After a while the Golden Chariot mine was discovered, several miles to the southward, but on the same mineral belt. This mine is the best in the "lower country," and has paid well ever since it was discovered. They have had a number of crushings that showed exceedingly rich ore. The writer remembers one run of 50 tons, yielding \$162 per ton; another of 52 tons, yielding \$257 per ton. This mine was a short time since put on the Stock Board, in this city. A fine mill has been put up, a wagon road built to the mine, and numerous improvements have been made. Advices from San Diego this week state that the last clean-up from this mine, after a two weeks' run, gave a yield of \$10,000.

The Owens mine, in Julian, has made some pretty good clean-ups, and in the eight months ending 1872, turned out \$42,319.50 from 920 tons of ore, with an average of 12 men at work. The eight owners made a profit on these eight months of \$18,109.25. The mine now has a fine set of hoisting works, and some gentlemen in this city are now interested in it.

Neither of these districts have had the advantage of the aid of much capital, and the developments made have been accomplished by their hard work and pluck. While the camps are not now particularly flourishing, there is enough work to keep a goodly number of men employed. One day last week \$13,000 in gold was received at San Diego, from these mines. There are five or six mills in the country, one small one on the Ready Relief mine, in the canon, being run by water power. The town of Julian, which supplied the miners, is being moved down to the canon, there now being more business done in Banner than in Julian district.

NEW COAL MINE.—F. M. Stone, of Monterey county, discovered some veins of coal on his ranch, about eighteen miles from San Benito, in 1870, which he has recently been prospecting with gratifying results, the indications being that they will be developed into extensive and valuable mines. One of them is eight feet in width, another nine feet, and the third about twenty-two feet. A shaft is being sunk on each of the veins.

An Important Invention for Quartz Mills.

The Cast Steel Shoe & Die Company, of this city, have just received through the MINING AND SCIENTIFIC PRESS Patent Agency, a patent on the application of cast steel to the manufacture of shoes and dies for quartz mills. This valuable invention was thought of about two years ago, by Mr. J. G. Kittredge, who is a well known iron and steel worker of this city, and who has since been quietly experimenting and laying his plans to fully perfect and bring the shoe and die into use. Numerous plans have been tried to crush ore by other methods than the old style of cast iron shoes and dies, for the purpose of lessening the expense, each better of five stamps wearing out about 1,000 pounds of cast iron every 30 days. Nothing has been found an improvement upon the iron shoes and dies until the application of steel to the same articles was hit upon.

The Cast Steel Shoe & Die Company was formed last year for the purpose of manufacturing and supplying quartz mills with these steel shoes and dies, and after many experiments in the methods of casting, forging and tempering the steel, they have succeeded in producing shoes and dies that they affirm will do the work of six sets of cast iron, costing about half the amount. The company now guarantee the steel shoes and dies in all cases to do the work of four sets of iron and save at least ten per cent. on the cost.

In some of the Crown Point Co.'s mills and at other mills where they have been experimenting, they have been found superior in every way to iron. First there is a saving in freight of about 75 per cent., then a saving of time in changing and setting up the shoes and dies, and of time lost by frequent breakage of the iron. It is estimated that each better of five steel shoes will crush at least a ton per day more rock than iron, as the steel wears uniformly and always presents a flat striking surface, while the iron wears hollow and uneven in the center of the shoes and dies.

In crushing gold rock the company are es- senced by mill men, that the steel are cheaper than iron at no cost at all, as the presence of the iron dust and chippings in the amalgam deteriorates from the value enough to more than pay the cost of steel, as by wearing so slowly the amalgam is not materially affected by the chippings. The steel shoes may be worn down to within an inch of the stem, much closer than the iron, without fear of breaking; the refuse steel may be used for pointing picks, facing hammers and other purposes.

The company are about to place their shoes and dies in all of the Crown Point mills, besides several large gold quartz mills in this State. They are now in use at the Chariot and Stone-wall mills, San Diego county, Idaho and North Star mills, Grass Valley, Phoenix mill, of Amador county, and a number of others, and the superintendents all give testimonials of their excellence.

Scientific Lectures and License.

Prof. Denton will no doubt return East with a huge disgust at some of the "ways that are dark," practiced on the Pacific Coast. He was arrested in Sacramento and put in jail because of his refusal to pay the license required by the city ordinance for lecturing. He had given a course of lectures on "Geology," and commenced another course of scientific lectures, when the city collector called on him for \$25, the sum required for permission to lecture one week. Prof. Denton refused to pay the demand, stating that it had been unusual all over the land, and he was accordingly arrested and put in jail. He refused bail, but accepted it on the next day, and was released.

The Professor published a card in the *Record* of Monday, in which he says: "I have lectured for twenty-two years in more than twenty states of the Union and in Canada, and I never before had such a demand made, except at Stockton, when I refused to pay it, and the city attorney found that the city charter did not allow them to enforce it. In many cities the City Hall has been given me for the expense of warming and lighting it. Sacramento alone has had the had distinction of making it a crime to enlighten the people, and of putting the man in prison who is guilty of it and will not allow himself to be fleeced by the city of the just reward of his labors. I ask for the sake of your city, for the sake of its people, for the sake of scientific lecturers, who have never yet been fairly remunerated for their services, to repeal this obnoxious law, and in so doing, I shall feel that my imprisonment has not been in vain."

The Sacramento ordinance under which the arrest took place, prescribes that a licensee shall be paid for an "exhibition, amusement, show, or performance." We do not remember hearing before that scientific lectures came under either of these heads. The State of California is just now receiving compliments the world over because one of her citizens has done so much in aid of science; but this little occurrence will dampen the ardor of our enthusiastic admirers. However, the press and public unite in a sentiment of indignation at the treatment experienced by Prof. Denton. The over officious collector is severely censured, and the people of Sacramento do not at all approve of the arrest. Scientific lectures are sorely ever remunerative enough to stand very much license tax, and if this officer is upheld, Sacramento will hereafter be omitted in the lecture engagements of others beside Prof. Denton.

Improved Method of Observing Altitudes of the Sun at Sea.

The science and art of navigation stand among the proudest achievements of modern thought and research. The accurate determination of the places of the fixed stars, and of the motion and position of the members of the solar system, gave the navigator numerous well determined points for observation. But the attainment of a corresponding perfection in fashioning instruments has ever baffled human skill, and ever will. For although we are entitled to look for wonders, at the hands of the artist, we cannot expect miracles! And we hence see that the demands of the astronomer, and even the nautical astronomer or navigator, will always surpass the power of the instrument maker. They must therefore so combine their observations, so familiarize themselves with all the causes which may produce instrumental derangement, and with all the peculiarities of structure and material of each instrument used, as not to allow themselves to be misled by its errors, but to extract from their indications all that is true and reject all that is erroneous.

It is true that the astronomer can so weigh his observations in the balance of the method of least squares, and so thoroughly sift them by Peirce's criterion, that hardly the trace of a large error remains; and the more minute errors being casual and accidental, sometimes lie one way, sometimes the other; sometimes diminishing and sometimes tending to increase the results. And, inasmuch as the theory of probabilities tells us that these accidental errors are as liable to lie one way as the other, we hence have but to greatly multiply our observations under varied circumstances and take the mean or average of the results obtained and we have this class of errors so far subdued, by thus setting them to destroying one another, that they no longer sensibly vitiate our practical results.

This principle of repetition, though so simple in theory and so beautiful in practice, when the instrument and observer are upon a firm basis, utterly fails of application where the observer and his instrument are tossed alike on the ocean's wave, and the object observed is "on wing." It becomes therefore imperative upon the navigator, if he would trace accurately his ship's path over the trackless ocean, that he attain rigorous correctness in the results of "each" of his instrumental measurements; and to this end his constant care and vigilance must be directed to the detection and compensation of errors, either by annihilating or taking account of and allowing for them. This latter method of taking account of and allowing for errors, is that ordinarily pursued by the navigator; but it has navigated so many noble ships to the bottom of the sea, that the voice of humanity and the interests of commerce alike demand such a modification of the methods of observation, and the forms of the instruments, as to annihilate effectually and alike errors inherent in the observer, in the instrument and in the atmosphere.

In the method of taking observations now generally practiced by the navigator, instrumental adjustments, atmospheric refraction and the impressibility of the optic nerve are all depended upon as constant and invariable during the observations; while, in fact, they all are ever fluctuating. The ever-varying fluctuations of heat and cold are continually changing the amount of atmospheric refraction, as also that of every instrumental adjustment. And it is a well known fact in optics that the irradiation (which causes bright objects to appear larger than they really are) varies with the length of time during which we look upon the object, during the first few moments of observation gradually decreasing; and then, as the optic nerve becomes fatigued, the optical illusion (irradiation) reappears magnified ten-fold. These are not mere speculative sources of errors, but practical annoyances which every observer has to contend with—the incompetent navigator, of course, slurring them over as refinements too delicate to deal with, while he attributes the error thus introduced into his position, to the action of imaginary ocean currents; but the thorough navigator meets these errors fairly, and sets about annihilating them. Yet it may be interesting to those navigators who insist on neglecting these finer instrumental errors, to know that very many of the sextants used in navigating vessels have an eccentricity ranging from one to four minutes, which is often aggravated by parallax of index-glass; and his positions are vitiated to the full extent of these neglected errors.

By the ordinary method of observing excessive contacts of the opposing limbs of the sun with the horizon, even if the mind from one observation to the other retains fresh and full the vision of the contact, still the observer will fail to make the contact of the horizon with the perimeter of the sun at equal distances from its center, because he makes these contacts at different instants of time, when the eye is differently affected by irradiation and fatigue. And hence, what would appear one moment a delicate contact would one minute afterward be wide of the mark. And thus it is, in the observations thus made with an instrument that is varying, with a vision that is varying and through an atmosphere that is varying, we can clearly see the source of the errors which have lured many an unsuspecting ship fatally onward against rocks and reefs.

But by the method of observing proposed by Mr. T. J. Lowry, of the U. S. Coast Survey,

and described by him at a recent meeting of the California Academy of Sciences, and with the form of instrument herein designated, we avoid in part, and in the remainder essentially annihilate these most fruitful sources of errors. By placing within the instrument itself the means of

Self-Correction

We have the most effectual checks upon its errors of construction and the changes of its adjustments. Thus, from very simple geometrical considerations it may be easily shown that the errors of eccentricity and of graduation are totally eliminated by the mean of the readings of two verniers 180 deg. apart, and by measuring the angles on different parts of the arc; and by using an index-glass susceptible of reversal between the parts of a set of observations we banish every trace of error from parallax of index-glass from our results. And every error of observation—such as arise, for example, from inexperience, defective vision, slowness in seizing the exact instant of occurrence of a phenomenon, and from atmospheric indistinctness, and insufficient optical power in the instrument—are all alike essentially checked by observing the contacts of the two opposing limbs of the sun with the horizon at the same instant. Now, since we have the contacts of the upper and lower limbs of the sun in the field of view at the same moment, we have before our eyes a most thorough check on the character of the contacts, since by direct and instantaneous optical comparison we make each of them equally well.

frame, so connected with a micrometer that its most delicate movements can be read off. In Fig. No. 2, a is the sun, and b , its duplicated image, as seen in the horizon glass; and c is this same duplicated image brought in contact with the horizon; d is the position of the observer. Now, in observing, it makes but little difference whether these duplicated images are exactly tangent, slightly overlapping, or slightly separated, (as shown at d , f , and e , in Fig. No. 4); for in the first case we have but to bring the horizon to the point of tangency; in the second, to bisect the two exterior angles; or in the third, to bisect the space between the adjacent limbs of the sun. It is obvious that this method of observing the contacts of both limbs of the sun at the same instant is equally well adapted for double altitudes; the appearance of the images then is shown at m , in Fig. No. 4. Other improvements devised by Mr. Lowry are: 1st. A reversible double reflecting index glass, (see Fig. No. 3,) which eliminates the error due to its parallax; and the 2d is making both faces of index glass reflectors, and fixing a glass prism, with silvered hypotenuse, on the line of sight behind the index glass and at such an angle as to reflect the rays first reflected from the back face of index glass parallel to the line of sight. This device enables us to measure any angle, (shown in Fig. No. 1.) It is obvious that any two angle reflecting instrument may also be made to give this duplication of images; and also give an altitude and its supplement at the same instant, and thus give us the algebraic sum of the existing refraction and dip. These improvements are all

IMPROVED INSTRUMENT FOR OBSERVING SOLAR ALTITUDES

And, moreover, since we make the contacts of both limbs of the sun with the horizon at the same instant, we have in "each sight," an altitude, complete in itself, without the aid of a supposition of the constancy of atmospheric refraction, or the stability of instrumental adjustments, or the constancy of the impressibility of the optic nerve, or the aid of memory.

But, as we cannot measure what we cannot see, it is obvious that by the ordinary method of successive single contacts those errors, too minute for low optical power, enter and vitiate the results to their full extent. But by Mr. Lowry's method of double contacts at the same instant, we detect and avoid these errors which would otherwise elude our vision. As for example, suppose we make what appears to be a contact of the upper limb of the sun with the horizon, and then by glancing at the other contact, of the lower limb and the horizon, in the same field of view, it will appear a contact equally nice as the other, if the first contact was exact, but if it was at all in error, then the second will be in error twice as much as the first; and thus it is, by doubling these errors, which the eye cannot discern nor the touch perceive, are we enabled to sift them from our observations. Still the observer should use this most powerful telescope available. The improvement now proposed by Mr. Lowry, (besides a few other matters of detail), in the ordinary reflecting angular instruments, is a device for duplicating the image of an object by optical means. This he accomplishes by fixing an extra index-glass directly above, or in the same plane with that of the ordinary one of the reflecting repeating circle, and at an angle therewith, equal to the apparent semi-diameter of the sun; or, perhaps, a more complete solution of the problem, is to fix a small sphere of Iceland spar on the direct line between the index and horizon glasses, (see Fig. No. 1,) and thus obtain two images of the sun equally distinct, (see s , Fig. No. 4.) This sphere to be mounted in a light metallic

equally adapted and easily applied to any reflecting angular instrument.

By making these attachments to the French reflecting, repeating circle (see Fig. No. 1) we have an instrument capable of not only eliminating its own errors, but those of observation, as well as those due to sudden atmospheric changes, and we have an instrument theoretically almost perfect.

Through the efforts of Laplace, Newton and Peirce the theory of nautical astronomy has reached a point of perfection that only awaits the determination of the true dimensions of the solar system (which it is hoped the next transit of Venus will give) to make it all that can be desired. The invention of the chronometer has practically solved the problem of longitudes. And the needle of the mariner's compass has felt the touch of a Ritchie and trembles no more. Whilst Beecher and Davidson have given the navigator artificial horizons that leave but little to be desired in that direction. But still improved methods of observation are wanted to decrease the frightful number of marine disasters. And though the ideas here advanced are believed to be a step in the right direction, yet they are also thrown out with a hope of eliciting from others a more complete solution of this problem, than which none other more interests mankind. And the complete solution of it—that would make practical navigation one of the exact arts—would evoke the lasting gratitude of civilized man the world over.

GRAVEL claims in the vicinity of Silver City are yielding liberally. Matthew & Co., who are working a claim in Nigger Gulch, a short distance west of the town, are making from \$15 to \$20 per day to the man.

ST. HELENA, Napa county, sent away 31,329 pounds of quicksilver during the first five months of this year.

Working Claims by Tunnels.

Willis Drummond, Commissioner of the Land Office, decided, Aug. 27th, 1872, that work done and expenditures made in constructing a tunnel, intended for the development and improvement of lodes, would not satisfy the legal requirements of the Act of May 10th, 1872, as to expenditure on claims; but that such expenditure or labor must be made in good faith upon each lode claimed; otherwise the same would be subject to re-location by other parties, as provided by law. The case which brought forth this decision was that of the Helmick Silver Mining Company, who were the claimants of nine separate lodes, all of which it was their purpose to develop and improve by a mining tunnel. This decision of the Commissioner was approved by W. H. Smith, Acting Secretary of the Interior. In consequence of this decision, a bill was introduced in Congress, which changed this law and amended it so as to read: "That the fifth section of the Act be and the same is hereby amended so that when a person or company shall run a tunnel for the purpose of developing a lode or lodes, owned by said person or company, the money so expended in said tunnel shall be taken and considered as expended on said lode or lodes, whether located prior to or since the passage of said Act; and such person or company shall not be required to perform work on the surface of said lode or lodes, in order to hold the same, as required by said Act." As far as we have learned, the bill has not yet been acted upon, although it is a just and necessary one.

However, it does not matter much, as W. W. Curtis, Acting Commissioner, has changed the ruling of Commissioner Drummond, as the following note to Senator Sargent will show:

GENERAL LAND OFFICE, WASHINGTON, D. C., May 23, 1874.—Hon. A. A. Sargent—Sir: Referring to your recent personal call, I have to state that where a tunnel is run for the development of a particular vein or lode, it is held by this office to be work upon that vein or lode within the meaning of mining Acts of Congress. The required expenditures may be made either from the surface of a mining claim or in a tunnel run for the development of such mine.

Very respectfully, etc., W. W. CURTIS, Acting Commissioner.

This is as it should be—only if it had been so decided before, it would have saved many miners considerable money.

THE PALACE HOTEL.—The new hotel now being erected on Market street, opposite the Grand Hotel, will cover an area of 95,250 square feet. The frontage on New Montgomery street will be 350 feet; on Market, 275 feet; on Annie, 350 feet, and on Jessie, 275 feet. It will be seen by this that our new hotel covers an area of ground nearly three times that of the New York "Windsor Hotel," which covers 36,000 square feet, and more than three times that of Leland's "Sturtevant House," which rests upon 30,000 square feet. About 4,000,000 bricks have been used already; when finished there will be 16,000,000 bricks in it; 16,000 barrels of lime and cement; and 600 tons of iron. There are now 300 men at work on the building, and 200 carpenters will be put at work when the structure is ready for them. There will be 30 miles of gas, steam and water pipe. The building will be six stories high and cost \$1,000,000.

TRANSIT OF VENUS.—Professor George Davidson, of the U. S. Coast Survey, and President of the California Academy of Sciences, will sail for Japan about the 15th of August or 1st of September, to take observations of the transit of Venus. O. H. Tittman, of the Coast Survey, who will be his chief assistant, is expected to arrive in San Francisco shortly with the outfit. Three photographers will accompany the party, all of whom are now practising with Dr. Dresbe and Professor Newcomb in Washington. The Professor has not decided on the exact point of observation, but intends to make his selection when he arrives in Japan.

PIPING COMMENCED.—Last week piping was commenced in the Emerson hydraulic claim in Happy Valley, Calaveras county. A new flume 720 feet in length, two feet wide, with a grade of six inches to the box, has been laid. The hydraulics has a pressure of 140 feet, the water—250 inches—being conveyed to the mine in a 13-inch iron pipe. The claim is several inches in area, the gravel varying from 60 to 100 feet in depth.

THE Brother Jonathan quicksilver mine, recently discovered by a party sent out by Dr. C. E. Davis, of St. Helena, consisting of T. Walker, W. C. Davis and B. E. Hunt, is now being worked. A company has been formed of the four above named gentlemen, a tunnel is being run, and the ore is said to be very promising.

BILLS of lading were received Monday by the Directors of the San Francisco Smelting Works for 345 tons of ore from Salt Lake, which will probably reach here Thursday or Friday. Operations will probably commence at the works the first part of next week.

EBERHARDT & AURORA.—It is rumored that a body of \$70 ore has been found under the old Peerless chamber in the Eberhardt & Aurora mine, White Pine. The mine is turning out 40 tons per day.

RICH discoveries of silver are reported about 10 miles north of Wells, Nev. The vein is large and the ore assays almost \$400 per ton.

Rock rifles are coming in vogue with miners in Montana, and are well liked.

Gold and Silver on the Pacific Coast.

How the Precious Metals are Prepared for Shipment.

When the gold and silver belongs to any of the great mining companies it is usually made up in bars and forwarded by express. Most of these companies have particular banks, either here or in New York, to which they sell all they have. But there are many small companies of white and Chinese miners who sell their dirt to the storekeeper with whom they deal, or to small country banks or brokers, who make a business of it, and who sell it to the big banks. Nearly all the banks have agents for purchasing in this way. The Bank of California claims to receive two-thirds of the bullion coming to the market. A comparatively small proportion of dust and nuggets is now received, as most of the country banks convert their receipts into bars. Gold was formerly sent along in its original state by nearly all these banks, but is seldom done now, as there is an assay office in nearly all the mining towns, where it is melted into bars. The average silver here weighs from 2,400 to 3,000 ounces, and the gold bars are worth from \$50 up to \$5,000. A few months ago the Anglo-California Bank received one of the latter value. The bars range in fineness from 600 to 950, the average being about 850. A great proportion of the fine bars come from Victoria, British Columbia. Silver comes in bars of all sizes. The Bank of California has had one bar of 1,801 ounces, or 124 pounds, sent to it. The gold and silver from the bank are sent to the refinery to be refined. Formerly, a good deal of silver used to accumulate at the banks, but now it is shipped quickly by the railroad. What remains over night in the banks is, being in the shape of bars, placed on trucks and run into the vault, till it is sent away next day. The silver is shipped principally to China, Japan and England. It is interesting to detail

How They are Shipped.

At the country banks it is received in all conceivable shapes, in plain bars, packed in buckskin bags, in tin boxes, and even in old tin cans. Silver coin for export is always put in square, dovetailed boxes. Silver bullion comes in plain bars. When sent from the bank it is put into a large bag, from which it is taken when brought to the railroad cars and placed on the floor of the car. In this way it is brought to the city. Most of the gold and silver is coined here and shipped away by the firm of Wells, Fargo & Co., which has agents at every principal point on the railroads, whose duty it is to receive it and check it. On the car are a number of men armed with small arsenal shot-guns and navy revolvers. They accompany the treasure. When shipped East it is put up in little boxes of pine wood with screwed lids, each containing about \$20,000. Wells, Fargo & Co. have about 600 offices on the coast and employ about 1,050 men. The offices extend from here to the Missouri river, and they have regular agents in Liverpool, Hamburg, Bremen, etc. They have agents on all the trains. It takes fifteen men to run a treasure car through from here to Ogden, and there are from two to six or eight on all the same of the smaller lines, while on the days when there is any considerable amount of treasure they have an armed guard. In sending to Mexico, a treasure-room is engaged on the steamer, in which the treasure is packed in boxes or bags. These are put in a square safe, which will hold \$250,000. Silver is almost always shipped in bars. For the carriage of gold from Fort Shaw in Montana, near the boundary line of British Columbia, to this city the charge is 1.45 per cent.; for carrying silver it is 3½ per cent. on the value. For shorter distances there is, of course, a reduced scale of charges.

What becomes of all the Gold and Silver?

In the first place, \$1,034,537,245 has been sent away from San Francisco through regular mercantile channels during the last quarter of a century. Nearly all this went by sea, though the amount exported in that way has been growing smaller, being now only a small portion of what it was a few years ago, before the overland railroad was completed. The balance, about \$40,000,000, on the Pacific Coast; \$60,000,000 has 000,000 worth, exists in the shape of coin, jewelry sent East by express, post-office and drafts, while the balance has been shipped from Utah, Nevada, Montana, Idaho, Colorado, New Mexico, Arizona and Wyoming, Oregon, Washington and British Columbia on the railroad since its completion, or by other means of conveyance previously, and carried away by private hand. Of the whole amount more than \$1,100,000,000 has reached England, chiefly by way of New York. Of that exported by sea more than half has gone directly to New York, about \$200,000,000 direct to England, nearly \$120,000,000 to China and Japan, and the balance to various other countries.

One Noticeable Change.

Occurring of late years, is in the character of our bullion product. Formerly it was all gold, or nearly so. In 1859 we began to obtain silver, when the yield of the argentiferous lodes of Nevada astonished the world more than did the placers of California; and ever since, year by year, the quantity of silver has been increasing while that of gold has nearly all the time steadily decreased. Last year the yield of silver on the Pacific Coast slightly exceeded that of gold. We have furnished the world with gold; we shall furnish it with silver. That the silver is needed may be well understood, when it is known that India alone requires \$500,000,000 worth of silver to supply her wants in this re-

spect. As to the future prospects, the silver yield of Nevada, Utah and Colorado is continually increasing, and the gold yield of the Coast will increase as soon as the vast unworked and almost unknown resources of this State are developed. It, in fact, may be considered that the resources, auriferous and argentiferous, of this Coast have as yet only been tested, and that the development has yet to come. The Rocky Mountains, the backbone of the continent, the Sierra Nevada and the connecting ranges, have, as yet, been but partially prospected and may be considered the inexhaustible storehouse of the precious metals.

Abroad there exists a kind of a vague idea that one has but to come to California and stay a dozen years to go forth a millionaire; but as to the total yield since the first miner struck the first pick in the soil of the valley of the Sacramento—as to the annual yield, whether it is increasing or decreasing—as to what becomes of it when mined, where it goes to and the part that it afterward plays in government and commerce, comparatively few are aware. And notwithstanding the expanded ideas of California wealth that exist abroad and at home, it will surprise not a few to learn that one-third of all the gold and silver coined and uncoined in circulation in the world, and a half of that used in America, Europe and Australia, has been the product of the Pacific Coast from 1848 to 1874.

The Precious Metal Product of the Coast.

Says the *Chronicle*, has nearly equaled a value of \$1,000,000,000, the exact figures being \$1,583,644,934, of which \$1,347,509,503 was gold and \$236,135,431 silver. But for this immense product poured into the coffers of commerce it is difficult to imagine how the latter could have been carried on, enormous as its increase has been, without a general and corresponding depreciation in prices, or a vast expansion of the system of credits and paper money. To the United States in particular it has supplied nearly \$900,000,000 of all the precious metals used in coinage and the arts since the foundation of the government. The total amount coined up to the end of 1873 was nearly \$860,000,000, of which \$750,000,000 has been from California gold and silver. What would have been done without this, and how commerce could have been carried on with foreign nations, are questions that are puzzling. It seems, indeed, that the general progress of not only the Pacific Coast, but of the whole nation, would have been very sensibly retarded. England, since 1848, has loaned eight thousand million dollars to the nation, and this she has been enabled to do by means of the gold and silver product of America and Australia—mainly of the former. At least five thousand millions of this sum, bringing a yearly interest of two hundred and fifty millions of dollars, has been derived from the Pacific Coast. Nearly all that we have sent East, and \$190,000,000 more, has gone thither, and has been loaned some half a dozen times. England lends gold and silver obtained from the United States, in exchange for goods, to France. France pays it back again for merchandise. Then it is borrowed by Germany, and by that nation paid back for manufactures, when it is again loaned to Russia, and so on. By this system one dollar in coin is sometimes made to perform the work of a dozen, and hence it is that the capitalists of England grow rich on the handling of the product of our lodes and placers.

The Product of Each Section of the Slope.

Of the whole yield California has produced three-fourths, or \$1,094,919,098, nearly all gold, with a small sprinkling of silver. It is thought that there exist mammoth silver lodes in various parts of the State, but they all pale their ineffectual fire before the wondrous ores of Nevada. This State comes next, having produced since 1860 upwards of \$221,402,412 in gold and silver, three-fourths having come out of the wonderful mines of the Comstock. The greater portion of this has been silver, although in many mines the gold forms at least one-third of the precious metals yielded in the assay. Utah, though long known as a country rich in the precious metals, has only lately been a producer of them. The Territory has produced \$18,527,537, principally silver, and is increasing in production at a great rate. In fact, its resources in this way are simply inexhaustible. Montana first became known in 1862, and for two or three years its placers gave great promise, but they have lately ceased to yield much, and quartz mining is not being pushed with sufficient vigor to make amends for the failure of the placers. It has produced altogether up to the present time \$119,308,147. The same may be said of Idaho, which has produced \$57,249,197. Colorado, as a mining field, is just about being developed, and will make for itself, by and by, as great a name as Nevada or California. It has produced about \$30,000,000. Oregon and Washington have a history very similar to that of Idaho. They have produced \$25,501,250. British Columbia has added about \$9,000,000 to the riches of the coast, and Arizona a small sum; but that Territory is capable of being made to export a large mining population. Its being named at present as a mining Territory is a seeming misnomer, as its yield is very small, but it has great and undeveloped mining capacities.

For the last seven years the yield of the precious metals on this coast has been increasing steadily, last year having increased about fourteen per cent., being \$80,287,436 against \$70,236,914 in 1872. This was principally due to Nevada, the increase of which, last year, was unprecedentedly great. But the yield of Idaho and Montana has been for some years decreasing,

on account of their placers being worked out and their quartz lodes not being efficiently developed. With the modes of working placers, hydraulic diggings and quartz mines, it is presumed that most readers have more or less acquaintance.

Trustees and Stockholders.

At a meeting of the stockholders of the Globe Consolidated Mining Company, to take into consideration the propriety of building a mill to be used for their especial benefit, 32,827 shares were represented, the number of shares in the company being 37,200. The president, M. D. Townsend, opened the meeting by stating in a brief speech the call for the meeting, which was, as before stated, for the purpose of hearing an expression of the different stockholders upon the subject. In the course of his remarks he stated that he had just returned from Virginia, and had taken a good deal of pains to look into matters connected with the Globe Consolidated Company, and he found upon investigation that there were some 20,000 tons of ore in sight, which would mill from \$15 to \$19 per ton, taking the average working of ores extracted from the same levels as a guide. Also, that the mills where they were now sending ore were about to increase the rates of crushing to \$14; that by building a mill of their own, the cost of milling would not exceed \$7 per ton. The extraction costing only \$1.50, there would be enough ore in sight to pay for a mill of 20-stamps, costing, according to estimates, from \$40,000 to \$50,000; and in conclusion, for himself, thought it would be a profitable investment.

To bring the question up for discussion, Thomas J. Smiley made a motion that the trustees be authorized to make a contract for the construction of the mill under the lowest responsible bid. The subject was then generally discussed, a Mr. Hunt, who claimed to know the poverty of the mine; being about the only person opposed. (He, however, still held his shares in a stock-gambling proposition). After considerable talk, the question of mill or no mill was put, which resulted in there being 20,982 shares in favor of a mill, and 1,965 against. The trustees, therefore, are ordered to make a contract to build the mill. As the secretary stated, there was nearly \$12,000 on hand up to the first of the month, and the expense of working the mine per month does not exceed \$5,000. There will need be an assessment of \$1 per share to secure the desired property.

It is rather of unusual occurrence for the trustees of mines to call a meeting of stockholders for the purpose mentioned, but considering the interest of outside holders, and their general want of confidence in mine managers, it was decided upon by the trustees to go out of the old beaten track and give all of the stockholders an opportunity to express their opinion, which, by the way, is an act of justice not commonly met with in mining companies. —Post.

The Hungarian Hill Claim.

A correspondent of the *Post*, writing from Quincy, Plumas county, says: There are large hydraulic diggings three miles from Quincy. Mr. J. D. Goodwin invited me to visit his Hungarian Hill claims yesterday. The route was about a mile by the stage road, toward Meadow (Shannon's) valley, and then up a very steep and very often sidling wood road until the summit of Hungarian hill is reached—a distance of two miles. The immense artificial cavern, formed by the process of washing away, has its awe-inspiring effect upon a person not in constant or frequent proximity to such perpendicular banks. We made a circuit around the "ecoop" of at least a half mile, and guided by a boy, whose principal business seemed to be to gauge the water gate, we made the rough and often slippery descent to the sluice-boxes. Here we found C. Gurnee, Esq., of San Francisco, attorney and counselor at law. In half miner's garb, and smoking a meerschaum pipe, he sat by the edge of the sluice and told us of the claim. He owns six-eighths in the claim, Mr. Goodwin being proprietor of the remaining one-seventh. I witnessed the taking up of a pan of the dirt and the gradual washing out, until \$500 dollars in gold were collected and cuddled at the bottom. The claim was purchased a year ago for \$30,000. Gurnee and Goodwin took \$30,000 from the bed-rock scrapings before they moistened a particle of the banks. By their better appliances they are drawing an immense revenue from the hill. They have expended \$60,000 in new ditches, reservoirs and pipes. They clean up, on an average, every twelve days, and it is easy to estimate the gathering at \$1,000 a day. They employ between thirty and forty men, inclusive of the watchmen for the ditches and sluices. They have 280 feet of water pressure; and the play of the "Little Giants" upon the rich red bank of the mammoth excavation seems to make the mountain tremble. This is a sight worth seeing many times; it is three miles from Quincy.

SURVEY.—A survey has been recently made for a tunnel to run from the Yuba river to Chimney hill, situated about half a mile from Cherokee, in Nevada Co. The hydraulic gravel claims in that vicinity, which are very extensive, for want of an outlet can now only be worked to a depth of from 40 to 100 feet. When the prospect tunnel is completed, the same ground can be worked to a depth of 300 feet, and over two miles of surface will be opened which it is now impossible to develop.

How the Pulse of the State Beats.

The pulse of the whole Pacific Coast beats through San Francisco. It is the financial and commercial heart of the country as far east as the Missouri river. The state of trade and manufacturers in it therefore correctly gauges the general prosperity. If the country is prosperous its stores are crowded with buyers, and its factories are busy from morning till night—cheerful with the sounds of labor. If the country is depressed, then so is San Francisco, its business men stand listlessly at their doors, their clerks lounge idly in the stores, the factories are half deserted, and the workmen squaltering by idly and hopelessly about the streets. The best sign, therefore, for returning prosperity to the coast is the tone and temper of business and manufacturing managers of this city. Judged by the prospect for trade generally, the condition of the State never was better. Almost every merchant now reports business lively, and the prospect for the future exceedingly encouraging. So also the manufacturers. To begin with

The Iron Foundries.

The Union reports three hundred and forty now employed, with a first-rate prospect for the balance of the year. The Pacific Foundry has one hundred and twenty-five men at present employed. The Risdon Iron Works have three hundred men at work, and the balance of the foundries a proportionate number. The proprietors all state that the prospective demand for mining machinery is good, as the rains of the winter and early spring have supplied enough water for mining purposes. If the expected demand is realized, there will be fifty per cent. more men employed than there are at present, and of course the demand for Pig Iron will increase accordingly.

The Boot and Shoe Trade.

Is growing more and more exclusively Californian every day. At least two-thirds of the boots and shoes sold in San Francisco this year will be of home manufacture. All the large factories are now actively at work, and the trade for the next four months is expected to be excellent. Rosenstock's factory has over two hundred and fifty white men at work. The United Working Men's Co-operative factory have sixty to seventy hands. Einstein Bros. are employing four hundred, and in their new factory is completed they have put on two hundred more. Hecht Bros. employ five hundred and thirty-five hands, two hundred more than last year. Hobart, Wood & Co. employ three hundred and fifty hands, one hundred more than the previous year. All the others report an improvement more or less, marked with a good outlook. In

The Lumber Manufacturing Business

There is more activity than there has been for years past. This is caused by the unrivaled demand for manufactured lumber; that is, lumber made into moulding, doors, casings, blinds, etc., for the hundreds of new buildings now being erected in this city. And before the year has closed it is anticipated that the requirement will be at least fifty per cent. ahead of what it is now, and that the labor employed will have to be increased proportionately. The manufacture of

Furniture.

Not long since, promised to be one of the healthiest and most flourishing of all that had taken root amongst us, but the State Prison Contract system, by which the labor of a couple of hundred men was obtained for one-eighth or one-tenth of the wages of a free mechanic, or for one-half those of a Chinaman, struck a mortal blow at it, and one which has produced very undesirable effects. It has certainly thrown back the business very considerably, notwithstanding which the same hopefulness as among manufacturers in other departments is now observable in this also, though all in the trade are a little disheartened at the renewal of the contract. The manufacture of

Cane Goods

Is going to be one of the greatest that can be carried on in California. There is no other State in the Union that offers such facilities for fruit growing as this, and few, where in three or four years more fruit will be grown. Even this year the yield is anticipated to be enormous, in many places fully doubling that of last year. Of course, only a small portion will be needed for local consumption, most of it being packed in tins for sending abroad. The Eastern people have only just begun to acquire a taste for California fruit, and Europe has as yet hardly been tried, so that the future of this industry is bound to be most brilliant. This year there will be at least 2,000 hands employed in this city, as opposed to 1,500 employed during the packing months of 1873.

The Cigar Manufacture

Too, owing to the great Eastern demand will be fifty per cent. more than in 1873; and, of course, a proportionately larger number of men will have to be employed. The increase in the manufacture of Cigars will give a needed impetus to Tobacco cultivation on this coast. In all

Other Manufactures

The outlook is very favorable. The car and carriage makers will employ three hundred more men this year than they did last, and several hundred new men will be needed for the necessary repairs to the coming Wheat fleet. On the whole, not less than five thousand men, or fully fifteen thousand of population will be added to our city through manufactures and building, during the coming year.

Banking.

GRAND INDUSTRIAL EXHIBITION,

To be held under the auspices of the

MECHANICS' INSTITUTE

OF SAN FRANCISCO, CALIFORNIA.

Opening on August 18th, 1874.

The Board of Managers herewith announce that a grand Industrial Fair will be held in the city of San Francisco for 30 days, opening on August 18, 1874.

In view of the increasing commercial and manufacturing importance of San Francisco, its contiguity to and close connection with the various countries bordering on the Pacific, the managers have constructed a Pavilion having a floor area of 150,000 feet, and have invited to it all who are disposed to come and exhibit. All exhibitors will be placed on the same footing. Motive power will be furnished free.

The building will be open day and evening, and every facility will be extended to exhibitors and visitors.

Application for space must be made without delay to the Secretary of the Board of Managers, 27 Post street, San Francisco, and all inquiries will be answered and information extended promptly.

No space can be secured unless applied for before the 20th of July next. A. S. HALLIDIE, Pres.
13v28-3m J. H. CULVER, Sec'y.

The object of this school is to impart a thorough education in business affairs. It is open to persons of both sexes and of all ages. There is an English Department for those not sufficiently advanced for the Business Course. Sessions continue day and evening throughout the year. Students can enter at any time. All wishing to be successful should secure a practical education at this College. Send for "Heald's College Journal," and learn full particulars. Sent free to all by addressing E. P. HEALD, Pres. Business College, San Francisco, Cal. 2v27-ly

THE SECOND ANNUAL EXHIBITION

—OF THE—

Inter-State Industrial Exposition

OF CHICAGO.

Will Open September 8th, and Close October 10th, 1874.

SPECIAL FEATURES for this year are MACHINERY IN OPERATION, and PROCESSES OF MANUFACTURE. The largest and best Exhibition Building on the Continent. The most liberal arrangements for Exhibitors in every class, and the best and cheapest method of advertising for all Artisans, Manufacturers and Inventors. Space, Steam Power, and Shafting free. Applications should be made, as early as possible, to

JOHN P. REYNOLDS, Sec'y.

Chicago, May 25th, 1874.

ARE YOU GOING TO PAINT?

THEN USE THE BEST.

THE AVERILL CHEMICAL PAINT WILL LAST THREE TIMES AS LONG as the best lead and oil, without CHALKING; is of any desired color. It is prepared for immediate application, requiring no Oil, Thinner or Drier, and does not spoil by standing any length of time. It is equally as good for inside as outside work; over old work as well as new; in fact, where any paint can be used the AVERILL CHEMICAL PAINT will be found superior to any other. Any one can apply it who can use a brush, which truly makes it the FARMER'S FRIEND.

IT IS JUST THE PAINT FOR THE AGE.

IT IS SOLD BY THE GALLON ONLY.

One gallon covers 20 square yards 2 coats.

For further information send for sample card and price list.

MANUFACTURED BY

The California Chemical Paint Company.

PURCHASERS please say advertised in Scientific Press

General News.

THE CURRENCY QUESTION IN THE U. S. SENATE appears to be in very much of a muddle. The probable workings of the currency bill now before that body appears to be very differently understood. The bill fixes Jan. 1st, 1878, as the period for the beginning of the conversion of the United States notes into bonds of the three descriptions authorized by the Act of 1870. The theory of the bill, as understood by one party, is that a five-per cent. bond will be then at par in coin, and that United States notes, being convertible into them, will also be at par; that in the meantime United States notes will gradually appreciate to par, and that the appreciation will be gentle and slow, not exceeding three and a quarter per cent. per annum, so that specie payments may be brought about without oppression to the debtor class or the derangement of the business of the country. Others claim, on the contrary, that the bill is in favor of expansion; while still others hold that it is a fair compromise between the inflationists and resumptionists. Mr. Sherman says if the bill would settle the vexed financial question, if it would stop people talking about what kind of money they were going to have, and go to work to earn it, it would be a blessed thing; but he did not believe it would have any such effect. It is still doubtful what action the Senate will take upon the matter of the bill, if it passes as it stands.

ROYAL ENDORSEMENT.—It is said that Queen Victoria has sent an autograph letter to President Grant, fully endorsing Mr. Sartoris as one every way worthy the hand and heart of the daughter of a President of the United States. It is also hinted that the royal heart will probably be moved to give some special mark of approbation of this union, by inviting the couple to visit Windsor Castle and conferring some title of nobility upon the bridegroom. It is also said that this action has been prompted from the sincere personal attachment which the Queen formed for Miss Grant, during the brief visit which that young lady made to the palace on her former visit to Europe, and also for the esteem she feels for the President of this Republic in his official capacity.

BEET SUGAR IN FRANCE.—The amount of juice expressed in France from beets, for manufacturing into sugar, for the year ending in October, 1873, at which time the grinding for that year's crop is being prepared for, is represented to be 485,746,810 gallons, being less than that of the previous year, by 38,642,523 gallons. In 1872, the density of the juice was 3.9, while that of 1873, was 4. The sugar produced in 1873, was 224,268,210 pounds, less by nearly 20,000,000 pounds, than in 1872. French sugars are also stated to have become a formidable rival to Austrian sugars. It is not improbable that beet sugar will yet drive cane sugar from the market, unless the planters of cane devise some means to reduce the cost of cultivation.

SOUTH CAROLINA UNDER RULE OF CRIMINALS. A special correspondence from Charleston says South Carolina has more criminals in office than any other State, and that the official records show that one-third of the persons holding minor positions have been indicted for offences during their term of office, and a much larger proportion of offences committed prior to election or appointment. In Charleston county nearly every State officer, from the highest to the lowest, has been charged, and many convicted of one or more offences.

THE RAILROAD COMPANIES between this city and St. Louis have tendered the ladies of this State free transportation for 20 tons of provisions to St. Louis for relief of the Louisiana sufferers. The Mail Steamship Company has also made a similar tender of free transportation for the same amount. Forty tons of provisions may thus find free transit, if the people of this State who cannot afford the money, will thus furnish the substantial need.

CROPS ON THE TULE LAND.—Circumstances that have favored crops this season in the valley and the foothills, the latter especially, have been rather unfavorable to those on the tule land, though the average production of these lands, will, it is said, still be large. In some cases the estimate is placed as high as 70 bushels to the acre. The breadth of tule land sown to wheat and barley is greater than that of last year.

A GREAT storm visited the Eastern States, and particularly Rhode Island, on Monday of last week, which did an immense amount of damage in causing freshets throughout the central and southern portion of New England. Seven inches of rain fell at one locality on Sunday night, the 7th instant, the largest fall of water ever before recorded in that locality.

THE paper mill of S. P. Taylor & Co., on Paper Mill creek, Marin county, has four paper or rag engines propelled by a 100-horse power steam engine. Its capacity is one ton of white or newspaper per day, and 1,600 to 1,800 pounds of brown.

SUN STROKE.—Two cases of sun stroke have been noted in this State during the past week; one in this city and one in Petaluma. Such cases have heretofore been almost unknown in this State.

DEAD LOCK.—There is a dead lock in the election for United States Senators from Rhode Island.

The reported discovery of immense deposits of guano in Southern Peru is confirmed.

Arizona Mining Prospects.

Chas. O. Brown took out to the Oro Blanco mine this week a complete outfit to commence work on the northern extension of the Oro Blanco mine, which is owned by C. O. Brown, E. M. Pearce, J. W. Hopkins and Gov. Safford. The company have built four arastras and will at once commence reducing the ore. Careful tests warrant the belief that the ore will pay \$100 per ton in free gold, and the company have sent out animals and a good set of practical miners to commence the work, with sufficient supplies to last two or three months. The prospect is encouraging for good returns.

The original Oro Blanco mine owned by Messrs. Handy, Leatherwood, Hewitt, Bartlett, Hopkins, Brown and Ferguson, has been worked for several weeks, and arastras are now in successful operation on this mine. Several other valuable mines have been discovered in the vicinity, and more or less prospecting is being done on them.

Good reports continue to come in from the Sacaton and Quajata mines. Small lots of gold and silver are constantly being brought to town by prospectors, and these lots aggregate from \$500 to \$1,000 per week.

The miners are now thoroughly in earnest. They have waited long enough for capitalists to come and help them, and they find the mine extensive and rich enough so that they can with strong arms and willing labor help themselves.—*Citizen*.

THE FISHES FROM THE EAST, AND WHAT HAS BEEN DONE WITH THEM.—The aquarium car, as already announced, has this time made the transit of the continent, safe, and its assortment of fishes has been safely delivered at appropriate points throughout the State. Its first stopping place was at the Truckee river, where three cans of fish were safely transferred to that stream. Another lot was left at Summit Station, to be deposited in the head-waters of the Yuba. The Western bass and Mississippi catfish were dropped in the San Joaquin at the point where the railroad crosses that stream. Seven cans of horn pout and fresh-water eels were placed in the Sacramento river, near Sacramento city. The perch were sent to the lakes at Sutterville, and from thence they will find their way to the Sacramento. The lobsters were brought to this city, and deposited in the ocean, on Saturday of last week; while the salt-water eels and a few tautog were deposited in the waters of the bay. Another lot of bass has been sent to Napa creek. The catfish have been put into our waters, notwithstanding the urgent protests of many who feared they would become troublesome. This fish is very destructive to small fry, and has a mouth of wide capacity, to aid in its natural propensity; but it is a most excellent delicacy for the table, and Mr. Stone, the Fish Commissioner, says they can never injure the salmon.

VALUABLE MINERAL CABINET.—A very valuable cabinet of minerals, which has been on exhibition for some time at the office of the Grand Hotel, is now offered for sale. The collection is a very rich and choice one, and contains some specimens which we presume cannot be duplicated on this coast. Any person desirous of obtaining such a cabinet will do well to call upon the owner, Mr. Henry Truella, as above, who has spent some twenty years in collecting the same. It will be sold for much less than its actual value.

WATER from the Iowa Hill canal was introduced into Iowa Hill last week, and the event was the occasion of a grand celebration, by a salute of guns, fire-works, torch-light procession and a ball. The canal, when completed, will be 40 miles long, and will have cost \$500,000. A great mining revival in that section is expected.

THE Metropolitan mill near Hamilton, Nevada, has been leased for a custom mill, and the lessees are making a success of their operations.

HYDRAULIC mining on Cedar hill, north of Virginia City, is being resumed after a suspension of several years.

A WAGON road is at last opened into Yosemite and no more horseback riding is necessary, to get into the valley.

PROF. E. S. MORSE is delivering a course of lectures in this city, on natural history subjects.

NEVADA, with a population of 50,000 souls, boasts of 18 newspapers, seven weeklies and 11 dailies.

THE Live Oak quicksilver mine, situated on Carrie's ranch, was recently sold by its discoverers to I. P. Allen, of San Francisco.

THE coinage at the Carson Mint for May amounted to \$571,352 94.

WORK on the Livermore coal mine is to be immediately resumed.

THE quicksilver mines in the Pine Flat district are doing well.

THE Virginia Consolidated mining company is about putting up a new sixty-stamp mill.

THE Eureka and Palisade Railroad is being vigorously pushed ahead.

CINNABAR is still being discovered in Lake county.

ROCHESTER DISTRICT.—Mr. P. H. Meagher, of Rochester, was in town yesterday. He informs us that there are now sixty men working the quartz mines of the Rochester district. Oaks & Meagher's lode is turning out an abundance of rich ore. They have ten inches of very rich ore. Every lode in the district is looking well, and every body in the camp is contented. This camp had been entirely abandoned; for years not a man had been in it until last summer; but it is now, probably, the best quartz mining camp in the Territory. So much for development.—*Montanian*.

THE town of Murphy's, in Calaveras county, was visited by a disastrous conflagration, Friday, 30th ult. The fire originated in Doyle's fruit store, and destroyed every wooden building on that (south) side of the street, from Sperry & Perry's hotel to Rowland's store.

THERE are eleven woolen mills on the Pacific coast—eight in California and three in Oregon. They have in the aggregate 28,840 spindles and 232 broad looms.

PATENTS & INVENTIONS

A Weekly List of U. S. Patents Issued to Pacific Coast Inventors.

[FROM OFFICIAL REPORTS FOR THE MINING AND SCIENTIFIC PRESS, DEWEY & CO., PUBLISHERS AND U. S. AND FOREIGN PATENT AGENTS.]

By Special Dispatch, Dated Washington, D. C. June 16th, 1874.

FOR WEEK ENDING JUNE 2, 1874.

STENCH TRAP.—John P. Schmitz, S. F., Cal.
CHOPPING BLOCK.—Henry Anderson, S. F., Cal.

PROCESS IN THE MANUFACTURE OF ARTIFICIAL STONE.—Gilbert S. Dean, S. F., Cal.

PROCESS OF PRODUCING PHOTOGRAPHIC PICTURES.—James M. Pimental, S. F., Cal.

HYDRAULIC LIFTING JACK.—Anthony J. Ojeda, S. F., Cal.

UNLOADING HEADER WAGONS.—Henry Klehn, Crow's Landing, Cal.

HARROW.—William H. Wolfe, Santa Clara, Cal.

SCRAPER.—Edward H. Farmer, Chas. Remington and Joseph Dimmock, S. F., Cal.

STAGE SOENERY AND SHIFTING DEVICES.—Henry F. Parsons, Los Angeles, Cal.

The patents are not ready for delivery by the Patent Office until some 14 days after the date of issue. NOTE.—Copies of U. S. and Foreign Patents furnished by Dewey & Co., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest time possible.

The Mining & Scientific Press.

Started in 1860, is one of the oldest weekly journals now published in San Francisco. It has been conducted by its present proprietors for ten years, during which period it has been repeatedly enlarged and constantly improved. The active and steadfast efforts of its publishers have gained for its conduct an amount of practical experience greater than any other publishers have accumulated on this coast, of a weekly journal.

The sum paid by us for the best editorial talent obtainable for our special class journal; for engravings, for interesting news and correspondence, and for printing a large-sized, handsome sheet, is unequalled by that of any other American weekly west of the Mississippi. As a PRACTICAL MINING JOURNAL it has no rival on this Continent.

It is the only MECHANICAL, and the only SCIENTIFIC journal of the Pacific States.

Every Miner, Assayer, Millman, and Metallurgist in the United States should take it.

Every Pacific Coast Mechanic, Engineer, Inventor, Manufacturer, Professional Man, and Progressive and Industrial Student should patronize its columns of fresh and valuable information.

Every Mining Engineer, Superintendent, Metallurgist, Mine Owner and Mine Worker in the world should profit by its illustrations and descriptions of New Machinery, Processes, Discoveries and Record of Mining Events.

Every intelligent thinker in the land, in high or humble situation, who would avoid literary trash for genuine information, should SUBSCRIBE AT ONCE.

DEWEY & CO.,

No. 338 Montgomery street, S. F.

A Good Binder for \$1.50.

Subscribers for this journal can obtain our Patent Elastic Newspaper File Holder and Binder for \$1.50—containing gilt title of the paper on the cover. It preserves the papers completely and in such shape that they may be quickly fastened and retained in book form at the end of the volume, and the binder (which is very durable) need continuously for subsequent volumes. Post paid, 25 cts. extra. It can be used for Harper's Weekly and other papers of similar size. If not entirely pleased, purchasers may return them within 30 days. Just the thing for libraries and reading rooms, and all who wish to file the Press. Lamp

HINTS FOR INVENTORS. We will send on receipt of stamp for postage, FREE, our 52-page Circulars containing 112 Illustrated Mechanical Movements; a digest of PATENT LAWS; information how to obtain patents, and about the rights and privileges of inventors and patentees; list of Government fees, practical hints, etc. Address DEWEY & CO., Publishers and Patent Agents, San Francisco.

New Inventions!

Of real merit, if brought plainly before the public when fresh, are most likely to become profitable to the patentee. For this reason, patentees (of worthy devices) should have the best of Engravings Made, and published in the Press. Superior Engravings Made, at reasonable rates, by artists in this office. br-tf

THE NEW U. S. MINING LAWS.

The new Laws of 1872, governing the location and purchase of Placer and Quartz Mines and Agricultural Lands in Mining Districts of the U. S., printed in circular sheet, for sale at this office. Sample copies, 25 cts.

DEWEY & CO.

American & Foreign Patent Agents,

OFFICE, 338 MONTGOMERY STREET, S. F.

PATENTS obtained promptly; Caveats filed expeditiously; Patent reissues taken out; Assignments made and recorded in legal form; Copies of Patents and Assignments procured; Examinations of Patents made here and at Washington; Examinations made of Assignments recorded in Washington; Examinations ordered and reported by Telegraph; Rejected cases taken up and Patents obtained; Interferences prosecuted; Opinions rendered regarding the validity of Patents and Assignments; every legitimate branch of Patent Agency Business promptly and thoroughly conducted.

Our intimate knowledge of the various inventions of this coast, and long practice in patent business, enable us to abundantly satisfy our patrons; and our success and business are constantly increasing. The shrewdest and most experienced Inventors are found among our most steadfast friends and patrons, who fully appreciate our advantages in bringing valuable inventions to the notice of the public through the columns of our widely circulated, first-class journals—thereby facilitating their introduction, sale and popularity.

Foreign Patents.

In addition to American Patents, we secure with the assistance of co-operative agents, claims in all foreign countries which grant Patents, including Great Britain, France, Belgium, Prussia, Austria, Victoria, Peru, Russia, Spain, British India, Saxony, British Columbia, Canada, Norway, Sweden, Mexico, Victoria, Brazil, Bavaria, Holland, Denmark, Italy, Portugal, Cuba, Roman States, Wurtemberg, New Zealand, New South Wales, Queensland, Tasmania, Brazil, New Grenada, Chile, Argentine Republic, AND EVERY COUNTRY IN THE WORLD where Patents are obtainable.

No models are required in European countries, but the drawings and specifications should be prepared with thoroughness, by able persons who are familiar with the requirements and changes of foreign patent laws—agents who are reliable and permanently established.

Our schedule prices for obtaining foreign patents, in all cases, will always be as low, and in some instances lower, than those of any other responsible agency.

We can and do get foreign patents for inventors in the Pacific States from two to six months (according to the location of the country) sooner than any other agents.

Home Counsel.

Our long experience in obtaining patents for inventors on this Coast has familiarized us with the character of most of the inventions already patented; hence we are frequently able to save our patrons the cost of a fruitless application by pointing them to the same thing already covered by a patent. We are always free to advise applicants of any knowledge we have of previous applications which will interfere with their obtaining a patent.

We invite the acquaintance of all parties connected with inventions and patent right business, believing that the mutual conference of legitimate business and professional men is mutual gain. Parties in doubt in regard to their rights as assignees of patents, or purchasers of patented articles, can often receive advice of importance to them from a short call at our office.

Remittances of money, made by individual inventors to the Government, sometimes miscarry, and it has repeatedly happened that applicants have not only lost their money, but their inventions also, from this cause and consequent delay. We hold ourselves responsible for all fees entrusted to our agency. The principal portion of the patent business of this coast has been done, and is still being done, through our agency. We are familiar with, and have full records of, all former cases, and can more directly judge of the value and patentability of inventions discovered here than any other agents.

Situated so remote from the seat of government, delays are even more dangerous to the inventors of the Pacific Coast than to applicants in the Eastern States. Valuable patents may be lost by the extra time consumed in transmitting specifications from Eastern agencies back to this coast for the signature of the inventor.

Confidential.

We take great pains to preserve secrecy in all confidential matters, and applicants for patents can rest assured that their communications and business transactions will be held strictly confidential by us. Circulars free.

Engravings.

We have superior artists in our own office, and all facilities for producing fine and satisfactory illustrations of inventions and machinery, for newspaper, book, circular and other printed illustrations, and are always ready to assist patrons in bringing their valuable discoveries into practical and profitable use.

THE

AMERICAN TURBINE WATER WHEEL.

Recently improved and submitted to thorough scientific tests by James Emerson, showing the following useful effect of the power of the water utilized, being

THE HIGHEST RESULTS EVER KNOWN.

Percentage of part gate, $\frac{1}{2}$ 50.03; $\frac{3}{4}$ 59.64; $\frac{5}{8}$ 78.73; $\frac{3}{8}$ 82.53; $\frac{1}{4}$ 82.90. Percentage of whole gate, 83.14.

Mr. Emmerson says: "These are the best average results ever given by any Turbine Wheel in my experience."

A splendidly illustrated descriptive catalogue, or any further information desired, furnished on application to

TREADWELL & CO.'S UPRIGHT SAFETY ENGINES,

2 to 10 Horse Power.

MADE BY THE N. Y. SAFETY STEAM POWER CO.

Has tubular boiler, and therefore is secure against the dangers common to shell boilers. Power is taken from near the base, which avoids vibration or top-heaviness. Occupies but two feet square of floor space and is so simple a boy can run it. All its parts are easily accessible—a great advantage. Is complete in itself as a Portable Engine and Boiler, or the engine can be detached from the boiler and run independently, if required. Its main points are simplicity, safety, and economy. For printing offices, landries, factories, ranches, small repair and machine shops, or for hoisting wherever a small and safe power is required, they are peculiarly adapted.

Refer to the following parties who have them in use
E. DETTRICH & CO., Bag Factory, San Francisco;
PACIFIC CHEMICAL WORKS, San Francisco;
ST. IGNATIUS COLLEGE, San Francisco;
STEAMER "PELICAN";
STEAMER "COQUILLE";

TO HYDRAULIC MINERS.

I warn Hydraulic Miners not to be misled by the advertisement of Mr. F. H. Fisher. Said Fisher has been beaten in every suit to which he has been a party (respecting Patent Rights on Hydraulic Machines), whether as plaintiff or defendant.

His patrons have already paid over Five Thousand Dollars for license to use machines purchased of the self styled

"Only Reliable Party in the Business Who Protects His Customers."

Fisher's Machine is worthless unless the discharge pipe is furnished with appliances, the patent for which is owned by Messrs. CRAIG, and which Fisher is enjoined from making.

The Machine itself is also an infringement on another patent owned by the same parties.

All persons infringing on either of these patents

WILL BE PROMPTLY PROSECUTED.

I am sole LICENSEE to sell Machines manufactured under Craig's, Rice's, Macey's and Hoskin's patents.

I Guarantee Full Indemnity to all my Customers.

Machines of all sizes always on hand.

If you want a Machine that will give satisfaction, and do not want to pay for it twice over, buy an Improved LITTLE GIANT.

For further particulars apply to

R. HOSKIN, Dutch Flat,

Or R. R. & J. CRAIG,

Room 8, 240 Montgomery st., S. F.

WILLIAMSON & CORY, Marysville. Agents

CAST STEEL SHOE AND DIE COMPANY,

OFFICE—Room 28, Hayward's Building, 419 California St., S. F.
Patented CAST STEEL SHOES & DIES for Quartz Mills.

Price, 20 cents per Pound.

CAST STEEL DIE.

An improvement greatly needed—being Stronger, more Durable and Economical than Cast Iron; as the Dies, when worn down, can be welded to the Shoes as easily as bar steel; never break, keep their full striking surface. Battery of five shoes crushes one-ton more ore in 24 hours than Cast Iron Shoes, will wear as long as four set of Cast Iron Shoes, and can be worn down to 1/2 inch in thickness. The stubs can be welded into Picks, Hammers, etc.

—ALSO—

Cast-Steel Tappets, Cams, Hammers,

Gearing and Castings

OF ALL KINDS, A SPECIALTY.

It takes forty days to fill orders.

CAST STEEL SHOE.

THE SELDEN DIRECT-ACTING STEAM PUMP,

Mechanics' Mills, Cor. Mission & Fremont Streets, 3v28-3m-sa

Metallurgy and Ores.

Varney's Patent Amalgamator.

These Machines Stand Unrivaled.

For rapidity pulverizing and amalgamating ores, they have no equal. No effort has been, or will be spared to have them constructed in the most perfect manner and of the great number now in operation, not one has ever required repairs. The constant and increasing demand for them is sufficient evidence of their merits. They are constructed so as to apply steam directly into the pulp, or with steam bottoms, as desired.

This Amalgamator Operates as Follows:

The pan being filled, the motion of the muller forces the pulp to the center, where it is drawn down through the aperture and between the grinding surfaces. Thence it is thrown to the periphery into the quicksilver. The curved plates again draw it to the center, where it passes down, and to the circumference as before. Thus it is constantly passing a regular flow between the grinding surfaces and into the quicksilver, until the ore is reduced to an impalpable powder, and the metal amalgamated.

Settlers made on the same principle excel all others. They bring the pulp so constantly and perfectly in contact with quicksilver, that the particles are rapidly and completely absorbed.

Mill-men are invited to examine these pans and settlers for themselves, at the office, 229 Fremont Street, San Francisco.

Morris' Settler and Amalgamator.

PATENTED MARCH 25, 1873.

An important improvement in milling. Cheap, light, efficient and durable. Gains Quicksilver on working tailings. Is discharged from the surface in the center instead of the side, by means of a Siphon which extends to near the center of the Settler. Hardest casting weighs only 135 pounds. The sides and bottom of the Settler are made of wood, as also Mullers, placed vertically—the friction of which brightens the quicksilver. One of these machines is in daily operation at No. 616 Merchant street, (basement), San Francisco. Parties desiring information as to rights of use, purchase, etc., can address, FREDERICK MORRIS, 616 Merchant St., S. F.

STATE OF CALIFORNIA,)
CITY AND COUNTY OF SAN FRANCISCO,)

On this June 3d, 1874, before me, F. O. WEGENER, a Notary Public in and for said City and County, personally appeared Warren B. Ewer, George H. Strong, John L. Boone and Alfred T. Dewey, known to me to be the persons whose names are subscribed to the within instrument, and acknowledged to me that they executed the same.

Filed June 5.
W. HARNEY, County Clerk,
By W. STEVENSON, Deputy.
In witness whereof I have hereunto set my hand and affixed my official seal, the day and year first above written.
jnb-4t F. O. WEGENER, Notary Public.

THE ONE-PLUNGER JIG,

Delivered on R. R. Car at Denver, Col., or St. Louis, Mo.,

CONTAINING SIX SIEVES, END TO END,

Separates in one and the same operation—1. galena and sulphide of silver; 2. pyrites or blende; 3. tailings, containing no valuable parts; or, 1. gold; 2. pyrites; 3. tailings (quartz, etc.) containing no valuable parts; or, 1. copper; 2. tailings, containing no valuable parts. The One-Plunger Jig can be combined with existing stamp-mills with highly important advantages, as after amalgamation it will recover completely all fine metals and all base ores and all mercury out of tailings. It concentrates all fine metal ores to such cleanliness that low grade ores can be shipped, after concentration, as first-class ores. Its feed and discharge are automatic. Its construction offers better guarantee against loss and repairs than any other apparatus in use. For particulars, apply to the inventor.

F. CAZIN,
Mining and Civil Engineer, Denver City, Col.

Number 26.

Improved Mechanical Movement.

Messrs. E. Duffy and R. Swarbrick, of Oakland, Alameda county, California, have recently patented through the agency connected with this office, an improvement in the mechanical movement which is known as a substitute for crank motion, in which a continuous rotary motion in one direction is obtained from a reciprocating, rectilinear or pedal motion. The improvement consists in the employment of a bow-lathe, similar to the implement which is known as a watchmaker's lathe, for giving alternate rotary motion to the case, and pawl or pawls which move outside of the ratchet wheels, instead of the rack and pinion heretofore used.

In the present instance the invention is represented in the engraving as adapted for driving a sewing machine, but it will be readily seen that it can be applied in all cases where a crank is ordinarily used to produce rotary motion of a shaft. On the shaft (as shown in the engraving) are placed two ratchet wheels. Outside of each ratchet wheel is placed a loosely revolving case or drum, *d*, which carries one or more pawls inside of the case. The pawl or pawls engage with the ratchet wheel when the case is turned in one direction, and carry the ratchet wheels and shaft with it, while the wheel moves freely in the opposite direction without engagement.

To give to the cases, *d*, reciprocating or alternate semi-rotary motion, the inventors employ for each case a metallic box, *g*, which has an arm, *h*, extending from its middle as shown. This arm has a hole through it so that it can be placed upon a journal or shaft, *H*, at a point opposite the shaft which is to be driven. When thus secured, one-half of the bow extends above, and the other half below the case. A flat spring or cord, *i*, is then wrapped once around the case, *d*, and its opposite ends secured to the opposite ends of the bow, then forming what is known as a "watchmaker's lathe;" or, as in the present arrangement, two pieces of spring, *i*, *i*, can be used, one end of each piece being fastened to the case and then carried partially around the case in opposite directions, and thence carried to the ends of the bow to which their opposite ends are secured.

Now by giving the bow a reciprocating or semi-rotary motion about the shaft, *H*, the spring or cord, *i*, will cause the case to make a semi-rotation each way alternately. This alternate rotation of the case will cause the pawl or pawls to act upon the ratchet in one direction and rotate the shaft, while it moves freely in the opposite direction. When, as in the illustration, two ratchet wheels and two cases are employed upon one shaft, the pawls of each case will act upon these ratchets alternately so as to produce a continuous rotary motion of the shaft.

The treadle, *l*, is provided with a short arm, *j*, at one side of the toe, and another, *m*, at one side of the heel. The arm, *j*, is then connected with one of the bows and the other arm, *m*, with the other bow, by means of connecting rods, so that the motion of the treadle will give to the bows an alternate reciprocating motion, such as is required to produce a continuous rotary motion of the shaft.

Each of the pawls which engage with the ratchet wheels is suspended upon a short pin, which projects inside of the case from its side, and the end which is opposite the engaging point passes out through a hole in the rim of the case. This rim is placed loosely upon the case, so that the pull of the bands, as they are alternately drawn upon, will cause the rim to move slightly back and forth, independent of the case, and thus raise and lower the point of the pawl, so that it will draw back noiselessly after each engagement, without raking upon the teeth of the ratchet.

Fig. 2 shows the interior arrangement of the ratchet-wheel, pawl and case, and the manner of applying the band, *l*, and bow, *g*.

By this arrangement the inventors much improve the ordinary mechanical movement which is used as a substitute for the crank, and render it applicable for driving light machinery by treadle power. Having no dead point, it can be started from any position, and when used for driving sewing machines, it possesses the additional advantage of driving the shaft in one direction only, so that a stop or reverse brake is unnecessary.

Congress and the Mining Laws.

Congress has adjourned, and for the present miners may rest easy on the subject of mining laws, since our legislators cannot "tinker" with them again until December. Several of the bills relating to the mining interests failed to finally pass both houses, and, consequently, go over to the next session. The Ward bill, providing for the compulsory patenting of mining claims, was referred to the Senate Committee on Mines and Mining, and that committee hold it yet, never having reported on it one way or

for certain annual expenditures on mining claims. On the 1st of March, 1873, an amendment to the original Act was approved, which extended the time for the first annual expenditure on claims located prior to the Act of May 10th, 1872, to the 10th day of June, 1874. Early in May of this year a bill was introduced in Congress extending this time again to January 1st, 1875. Although the time as first extended—June 10th, 1874—was close at hand, it was not until late in May that it passed the Senate, after being favorably reported on by the Committee on Mines and Mining. About the first of June the bill finally passed the House; but it was not until within a few days of the 10th of June that the bill became a law by re-

FIG. 1.—IMPROVED TREADLE FOR SEWING MACHINES.

another. The Negley Amendment, which provided that the productive mines on the Comstock lode should take out patents for their ground, was reported on adversely by the Senate Judiciary Committee, to whom it was referred by the Senate Committee on Mines and Mining. Pratt's bill, which provided that all quartz lodes which had produced minerals to the gross value of \$5,000 should file applications for patents within one year, was not acted on by either house.

The bill providing for the admission of quicksilver free of duty failed with the Tariff bill, which hangs between the House and Senate on amendments. The bill allowing work done on tunnels to be reckoned as expended on the claims, under the provisions of the Act of May 10th, 1872, passed the House, but did not reach the Senate. This makes little difference, however, as, since this bill was introduced, the Acting Commissioner of the Land Office has reversed a decision of a former Commissioner, and rules that work done on tunnels, intended to develop a claim, is tantamount to expenditure on the claim. The bill abolishing the charge on gold coinage passed the House, but was not acted on by the Senate. Final action will not be taken on any of these bills until Congress convenes again in December.

The action of Congress, with reference to mining laws, this session, has been such as to keep the mining community in a continual state of anxiety. The miners did not know what Congress was going to do any more than Congress did itself; but Congress showed such an astonishing amount of ignorance about mining matters that the miners themselves did not feel very safe. The action taken with reference to the extension of time for the first annual expenditure on claims located prior to the Act of May 10th, 1874, showed such a disregard for the convenience of the miners that they were very much disgusted—not that they were displeased with the final conclusion of Congress, but that that body was so provokingly slow in making up its mind what to do.

The original law of May 10th, 1872, provides

ceiving the signature of the President.

This dilatory action caused great inconvenience to the mining community. A matter of so much importance, involving so much money, should have received immediate attention. Many miners did the required work, being afraid the bill would not pass and they would lose their claims. Others were at the expense of sending men to their locations to be ready in case the bill did not pass; and even after the bill did pass, some men commenced work for fear if the President did not sign it in time, some one would jump their claims and hold them by a technicality of the law. Another feature was, that there was great indecision as to the date of the extension of time. We were dependent entirely on newspaper dispatches

HARROW AND CLOD BREAKER.

for information on this subject, and these dispatches were very contradictory, some setting it at one day and some at another. If the members of Congress could have heard all the "growls" against them by the miners of this coast, they might have hurried up this business a little faster. However, Congress has done with mining, as well as other laws, for a few months, and the mining community can work ahead without any fear of obnoxious mining laws being passed at present.

JAMES THOMAS, of the Golden Gate mine, near Sonora, has invented a simple, yet ingenious, method of splicing wire rope, or attaching the end to any desired place, without tying the same. Splicing by this contrivance can be accomplished by one man in fifteen minutes, which now takes four men about six hours.

The forty-stamp mill for Lincoln mine, Sutter creek, was, on Tuesday, being loaded upon the cars at the Sacramento Valley depot.

Harrow and Clod-Breaker.

We give herewith a representation of a new Clod-Breaker, recently introduced into Oregon where it is said to be giving good satisfaction. This instrument has been devised with the view of meeting an urgent want of the tillers of the soil everywhere, but more especially soils of a heavy character, like the adobe soils of California. Referring to the accompanying cut, it will be seen that the implement is composed of two parallel bars or boards, united at each end so as to form a conveniently shaped frame. The boards or bars are curved upwards, at the forward end like the runners of a sled, so that they will not push the earth before them. Transversely across the frame, is a series of iron bars or stout iron wire stretched parallel with each other, thus forming one or more inclined drops which will so ride upon the clods as to cut or crush them into pieces. To further aid in this work, a double row of teeth, something like harrow teeth, are arranged in front, as shown, and slightly curved near the point, so as to give them a lifting action, by which the clods are brought to the surface, and thus within the action of the parallel bars which subsequently pass over them. A seat may be mounted upon the top, as shown, for the driver, whose weight may be added when needed, for the greater effectiveness of the machine.

This implement, we are informed, has been duly tested by those who are well qualified to judge of its merits; and the claims of the inventor, Addo Borchers, of Salem, Oregon, have been fully endorsed. The invention was patented through the MINING AND SCIENTIFIC PRESS Patent Agency. As Mr. Borchers is about to change his residence to this city, any letters in relation to the above will reach him if forwarded to this office.

Our Great National Anniversary.

Judging from present indications, our nation will celebrate the approaching anniversary of its independence with unusual heartiness and zeal. From all quarters reports are received of active preparations, and unity and harmony seem to prevail generally. In San Francisco arrangements are nearly perfected by means of which a celebration will be secured worthy of the occasion; while in other cities and villages, so far as heard from, similar preparations are being made.

An increased interest in holidays generally, and a disposition to keep and to enjoy them is one of the perceptible changes in the habits and inclinations of the American people. And especially since the war of the rebellion has the nation manifested an increased enthusiasm in celebrating those of a national character. This apparent change in regard to the keeping of holidays is commendable, even in connection with those of a social and festive character; but as manifested in an increased enthusiasm in keeping our national holidays it becomes a hopeful sign of growing patriotism.

THE WEATHER IN SAN FRANCISCO.—Our readers may possibly give a thought to the climate of San Francisco once in a while, and feel disposed to ask the always in-order question—"How's the weather?" In reply to such inquiries we would say that San Francisco is now enjoying delightful weather. The nights are perhaps a little too cold for the growing corn or the corner loafers, even; but San Francisco does not need to grow any of the former while of the latter she grows more than she needs under any and every dispensation of the weather. To the tourist now visiting this city, any splenic complaints against the weather now prevailing appear decidedly unreasonable. They declare that people who are not satisfied with our present standard of weather must be hard to please.

The following is the average yield per acre of the crops of Arizona Territory for 1873: Barley, 1,344½ pounds; wheat, 1,213 pounds; corn, 1,579½ pounds; potatoes, 7,853½ pounds; rye, 1,500 pounds; oats, 1,200 pounds; sugarcane, 24,000 pounds; tobacco, 800 pounds; vegetables, 5,875 pounds; and alfalfa, 20,000 pounds.

The Tuolumne Reunion.

One of the largest re-unions of the former residents of Tuolumne county, ever had in this State, assembled at Badger's Grand Central Park, East Oakland, on Wednesday of last week, June 17th, on the occasion of the seventh anniversary of that association. There were between 2,500 and 3,000 men, women and children present; and at least 1,500 of that number were former residents of "Old Tuolumne." The entire arrangements were complete in every particular, and for which great credit is due the entire management, but especially their retiring President, Mr. L. P. McCarty, who labored ardently for weeks previous to make it a success. It was a financial as well as a social success. Although their expenses were very large, they will net some \$200 from this last gathering.

The music, both instrumental and vocal, would have done credit to our first-class concert—for none but first-class artists participated. Among them were the entire members comprising Walcott's band; and of vocalists, Miss Fannie Marston, soprano; Mrs. Julia A. Cameron, contralto; Prof. Carmini Morley, tenor; Mr. C. Makin, baritone. The programme of dances was elaborately arranged, and the dances themselves sustained with zest.

At 12 o'clock the floor was cleared and the large assemblage was called to order by the President, and the programme carried out in full, with some additions. First a quartette, "Nights Shade no Longer," was sung by Miss Fannie Marston, Mrs. Julia A. Cameron, Prof. Morley and Mr. Makin. The song, "The Sword of Bunker Hill," by Mr. Makin, followed, which, taking into consideration the disadvantages of the Pavilion he had to sing in, was the best rendered we have ever heard it; after which came the poem by Hon. Walter Murray, who was received with immense applause, and proceeded to deliver the following poem, which at frequent intervals was received with enthusiastic demonstrations of approbation:

Hail Tuolumne.

The weary exile, heart sick and distressed,
Who deems of every land his own the best,
Strains at the chords which bind him to that home
From whence in luckless hour he chanced to roam,
And while his body weak and trembling stands,
Alone and friendless, within foreign lands,
Oasts back his soul, on spirit-wings to greet
Affection's smile, a kindred's fond heart beat,
His Nation's flag, and all those ties of earth
Which sanctify to him the country of his birth.

Not these the feelings that we hold for thee,
Our early choice, thou fair Tuolumne.
No Mother thou to us; our baby knees
Ne'er knelt before thee, and our infant teaze
Ne'er brought the flush of anger to thy brow—
Thou wert not Young Men then, as now,
Thou wert our glorious Mistress, in that time
When youth (not yet attained to manhood's prime)
Revels in Nature's hesitancies and adores
Far more the creature than the Great First Cause.
We wandered in thy palaces of pines,
We drank thy mountain air as richest wines,
We loved within thy happy mountain streams,
And, though not poets, shared the poet's dreams.
We delved beneath thy bosom, and drew thence
Thy hounteous treasures, rich in pounds and pence,
But richer still in those ambitions hopes
That soar beyond the poet's rhymes and tropes.
Some toiled to gain the mastery of men,
Some to woo Fickle Fortune's back again;
Some thought of father, mother, loved ones dear,
And planned to brush aside affliction's tear.
Some thought of one behind them, dearer far,
Their life's fond object and its guiding star,
For whom they dared to leave the toil and care
Which dog the wanderer's footsteps everywhere,
And counted all their perils cheaply bought
Could they but live in the lost dear one's thought;
Rich in the hope, oft groundless and frustrate,
To achieve at some long day a heart's home and a mate.

Ah! many a sacred hope was lost of old
In that wild, feverish, toilsome hunt for gold,
And far from home to stamp as sordid those
Who thus went forth to battle with the foes
Of youth, and strength, and high emprise, and health,
Nor hold them to blame, should the poet's vesith,
Perish the cynic who can only see
Mean impulse, where, perchance, divine may be.
Rather do I rejoice to know and see
So many friends of Old Tuolumne—
So many playmates of her younger hours,
So many comrades, dear to us and ours,
Whose life's long struggle whether lost or won,
Deserves the praise of each and every one.
Let us remember with an honest pride
All those who, battling 'gainst the adverse tide
Of Fate and Fortune, have impressed a name
On California's pregnant roll of fame.
And what if no o'er-mastering spirit stands,
A beacon light to this and other lands,
To speak of the high worth of that age,
Thou fairest country, proud Tuolumne!
Yet in the humbler record of brave hearts,
Of honest name, and sound, enduring parts,
Thou wilt mayst challenge all thy sisters fair
To meet with thee in emulous compare.
And you, my friends, who, whether you have part
In the record, or hold it to your heart,
Bear with me while from memory I recall
Some names that from our roll we can't let fall.]

Tis much I expect that those rattle, reckless, times
Could wed a churchman from my ruder rhymes;
And yet the very ground on which we stand
Tells of a Hamilton, whose hold, firm hand,
And free, fair record, speaks of mountain air
Inhaled of old in our Columbia's air.
And Harmon, too, whose useful life bears fruit
In teaching young ideas how to shoot,
Once, in Sonora's bright and early day,
"Pointed to brighter worlds, and lead the way."
Yolo has borrowed in our David Deal
A great deal more than we can from her Steel.

After the Church, the Law comes close behind,
And here a richer record we shall find.
For our Dwinelle, with just an equal way,
Dispenses justice to both side the bay;
Quint, the great champion of the Fair—her foe—
(Take either side you will), is ours, you know;
Martin, McGowery, Cavis, Elkins, Ford,
Each in his turn has wielded Justice's sword,
And Jeremy Letford, last of the old race,
Remains our Justice of the "Pace."
McNeill's bright ermine, brighter still appears
When horn upon our roll of Pioneers.

Congress sends back the names, still unforget,
Of Brave Ned Marshall and of Charles Scott;
Dorsey adorns Sonora, Walcott halls
From Contra Costa's land of pleasant valleys;
And Farrell, today's Orator, whose time
This State employs in prosecuting crime,
With forceful words our heart-beat quickens when
He mounts the rostrum or wields the pen.

And let us not forget the honored dead—
Green springs the turf on Barbour's resting head,
Whose polished speech once warmed the civic strife
And to forensic lore gave newer life.
And poor Ben Moore, the trusty friend of old,
Whose honest voice was never bought or sold,
May he enjoy a peace he never knew—
In the life-fervee he so well passed through.
And Coffroth, too, the eloquent, the sage,
The poet-orator, whose ripper age,
If spared, had brought to him a higher fame,
A greater labor done, a fuller name.

Pass we to living names: From San Joaquin
Hark to the drum that beats the march of King;
Evans, the statesman-warrior—the word
Recalls the flashing of the hero's sword;
List to the rifle-blast, the dismal cry
Of the fierce Indian's death agony—
Such he the messengers of peace we send
To woo the red man to a righteous end.

The clang of war, the thought of duty done,
Recalls the bright and honored name of Gunn,
Whose "mighty weapon," always in the right,
Ne'er faltered in the journalistic fight.
His son, a Douglas, is true son of thee,
And worthy of thy name, and ready hand,
And hold McCarthy, hero of the "Flag,"
The first in combat, and the last to lag,
In San Diego's hopeful land of "rail!"
His war-cry shouts, "There's no such word as fail!"
Washburne, the "Pilgrim" and the Pioneer,
His "otium cum dignitate" passes here,
And half forgets, in his Athenian air,
The time when Lopez had him by the hair.

And while I speak of comrades who have stood
In public service for the public good,
I call to mind our Mandeville, whose fate
Was to survey the Senate and the State;
Our Sedgwick, with his occupation gone—
For Local Option's cry is "Good-by, John!"
Our Chamberlain, whose proper place should be
Dispensing verse to duty, instead of me:
Who, long in office, yet ('tis past belief),
Although Receiver, never was a thief;
And Paul K. Hubbs, the Nestor of our hand,
Him of the silvery tongue and ready hand,
Who shining in the Senate, next was found
Suppressing smugglers in far Puget Sound;
And Charles F. Dodge, and Luckless J. S. Hoff—
And here comes the hearty name of "Thof."

A host of meed parade before my eye:
Radcliff, the high priest of the mystic tie;
Todd and Bertine, the founders of "Expressa";
Street, who brought lightning through the wilderness;
Herr Alexander, with us as I hope to-day,
And Taylor, from the village 'cross the bay;
And Long Tom Murphy, and Alonzo Green,
(Less green than some whom you and I have seen);
And classic Horner, and ready hand,
But one whose inspiration ne'er grows cold;
And last, not least, the Rutherford, whose art
Adorned our cities, acting well their part;
They helped to build the old-time mountain home.
May health attend them where'er they roam.

'Twas a good thought, from time to time, to bring
To social union and sweet communion,
So many comrades scattered far and near
To spend one pleasant day in all the year.
It rightly sprang from a fair lady's heart;
Therefore let Mrs. Sedgwick take part
To our remembrance, and let us remember, too,
Her worthy coadjutor, her true friend,
Their effort, small at first, commenced a tide
Which kindly thought and honest country pride,
Man's hearty impulse, woman's smiling eye,
The general sympathy, have swelled so high
That the huge wave, defying Time and Fate,
Sweeps from Sierra to the Golden Gate.

McCarty, too, deserves his meed of praise—
Our Active President, whose nights and days
Were freely given, and who, hand in hand
With Cunningham, McCusker and a hand
Of kindred spirits from our mountain heights,
Has helped to swell to-day the sum of our delights.

And let us hope that when again we meet
In this fair spot our loving friends to greet,
All those now present may be here to see,
And swell the cry—All hail, Tuolumne!

At this point of the exercises, by request,
Mrs. Julia A. Cameron sang (as a solo) "The
Days of Auld Lang Syne," which by many
was considered the gem of the day, not only
for its appropriateness, but as well the way
it was rendered.

Miss Fanny Marston next sang "Three Cheers
for the Red, White and Blue" with much
patriotic feeling, and was followed by Prof. C.
Morley, who received a shower of applause
(equal to an encore) for so feelingly singing
the simple ballad, "Thou Art so Near, and yet
so Far." Then followed

The Oration.

This, although an extempore effort, was exceedingly appropriate to such an occasion. The allusions to the distinguished dead pioneers of "Tuolumne" were exceedingly affecting. The eulogies of Coffroth, Solomon, Barber and others produced a profound sensation. The orator, Robert Fernal, of San Francisco, was vociferously applauded at the close of his admirable production, which stamps him as one of the rising orators of our State. In closing his remarks, he very happily referred to that day, June 17th, being the 99th anniversary of the "Battle of Bunker Hill," when he fairly aroused his audience to a pitch of frenzy, referring to the scenes enacted following that battle in our country's history.

"The Star Spangled Banner" was then sung by Miss Marston, Mrs. Cameron, Prof. Morley and Mr. C. Makin, and could not well have been rendered better. The solos performed by E. Schlott, on the French horn, and Signor Caspari on the clarinet, were the great features of the day. Prof. Gustave Scott accompanied the soloist on the piano.

The Collation.

The literary exercises concluded with the solo of E. Schlott on the French horn. Immediately thereafter came two hundred ladies and gentlemen, on invitation of the managers, repaired to the long howling alley adjoining, which had been gracefully decorated with flowers and evergreens for the collation. Tables

extending the length of the apartment, beside a shorter table in a side room, were spread with a feast of good things. President McCarty presided, with W. G. Dinmore, Treasner, on the right, and Mrs. Soderer, one of the founders of the association, on the left. There was no formal speech-making at the banquet, but the President proposed "To Our Guests, the Poet, Orator, Music and the Press," which was responded to by the reporter of the *Alto*, in this wise: "To the President of the day," etc.

Election of Officers.

After the inner man had been satisfied, the dancers repaired to the Pavilion, and the members of the association to the grove, where an election of officers for the ensuing year was had. Here several speeches were made, and sentiments proposed by retiring and newly elected officers. Mr. Dinmore especially paid a handsome compliment to the press, for the frequent, timely, and liberal notices made of this festival in their columns.

The following named were duly elected officers of the Tuolumne Re-union Association for the ensuing year: President, Jas. L. Homer; Vice-President, Hon. Stephen Wing; Secretary, Hon. P. B. Bacon; Treasurer, Wm. G. Dinmore; Executive Committee—Z. H. Cunningham, H. Jacobi, H. M. Rosekrantz, A. Sharp.

Smelting Operations at White Pine.

From reliable information received during the week, says the *White Pine News*, we are gratified to learn that smelting operations will soon be commenced in this district. We are also pleased to note the generally expressed desire to aid in forwarding this material interest, and feel confident in the result of the proposed experiment, believing that all engaged in the same will be amply remunerated. Mr. Prescott, a gentleman whom we have known as a practical and successful smelter at Enreka, has been spending some days looking at our mines and talking with our miners, having in view the feasibility of working our ores, preparatory to commencing operations on their reduction, and has decided to make a start as soon as possible. One thousand tons of rock have been engaged from different parties, and the Mattison furnace will be at once repaired sufficiently to allow of running through the lot in order to demonstrate the fact that our base-metal ores are susceptible of successful treatment by the smelting process. We regard this movement as the initial point from which to date our future prosperity and success as a bullion-producing district. A new incentive will be given the miner for the development of his locations, and new and valuable discoveries will result from the encouragement held out in the shape of certainty of profit to be derived from their labor.

It will indeed be a happy awakening from the lethargy which has been a characteristic of White Pine for the last few years, and all should be thankful that our deliverance seems so near at hand. Once made manifest that we possess the means of producing untold wealth in the shape of precious metals, and no other indolent need be held out to men of means to invest capital in our country. With the now certain fact that good, merchantable coal exists in large quantities, within a distance of fifteen miles, from which a superior article of coke can be made, the introduction of which will materially lessen the cost of smelting, united with the advantages to be derived from the experience of our neighbors at Enreka, no doubt can exist that an additional profit will accrue. We confidently believe that before another winter makes its unwelcome appearance among us we shall have occasion to welcome many former residents of Hamilton back again to their old home. Our faith in White Pine is, as ever, unbounded, and we say to all unbelievers—wait a little longer and see if our earnest predictions are not more than verified. It shall be henceforth, as it has always been, our constant aim to advocate every and all measures having a tendency to advance the interests of our country, without fear or favor, and to this end we earnestly request all to supply us with whatever information may be in their possession. In conclusion, we urge upon our people the imperative necessity that exists of doing all in their power to make the trial about to be commenced by Mr. Prescott a perfect success, as on this attempt rests much of our future prosperity.

THE WAGON-ROAD IN YOSEMITE VALLEY COMPLETE.—After years of promise and years of delay, we are at length in a position to announce that a wagon-road has been completed into the Yosemite Valley, and that it is, therefore, no longer necessary to use the saddle in making the trip to it. The road was built by private enterprise, without State aid, the privilege of collecting toll being the only remuneration. The new road is available by two of the four routes to the valley, viz: that by Coulterville, and that by the Calaveras Big Tree Grove and Chinese Camp. The time of starting from the city has been changed and the time consumed in reaching the valley greatly shortened. Tourists now leave at 7 A. M. instead of 4 P. M. They reach Merced at 4.30 and take dinner there; thence to Snelling's on odd days of the month only; stop overnight at Snelling's and leave at 5 A. M. next day, and arrive in the valley the same night at 7 P. M. Returning, leave the valley hotels at 5 A. M. and arrive at Merced the same night and stay over there; leave the next morning at 5.20 A. M. and reach the city at 12.40 P. M. the same day. Those who have heretofore been deterred from visiting Yosemite, because of the necessity of using the saddle-horse, have now that prohibition removed.

Mining Development.

Notwithstanding the decline of the mining interests in Tuolumne and Calaveras counties, caused by the exhaustion of the shallow placer diggings, there is good reason to believe that the mineral wealth of those regions is but partially developed, and that rich strikes will be there made for many years to come. There are immense deposits of gold-bearing gravel which will be eventually worked by the hydraulic process, and the return will be equal to that received from the famous hill digging in Placer and Nevada counties. The quartz mines have not yet been thoroughly tested, and although many have been successfully worked for a time and have yielded large sums of bullion, yet at present there are few claims that have been opened to the depth that mines of a similar nature in other portions of the State were worked before their value was fully demonstrated. The Gwin mine, in Calaveras, is now probably one of the best in the State, yet its enterprising proprietors have several times met with discouragements that would have caused less persevering men to have abandoned the claim. The mine is now worked to a depth of over seven hundred feet, and the prospect for the future is better than ever before. It is not reasonable to suppose that this is the only mine in that portion of the State, and without doubt, other claims if worked as systematically and intelligently as that has been, might be shown to be equally valuable.

The great difficulty thus far has been that persons were more willing to invest their capital to develop mines in Nevada, or at some distant point, rather than in our own vicinity, although the prospect of securing a paying mine has been generally better in California than elsewhere. There is, however, apparently a change in sentiment in this respect, and mining experts and prospectors are now giving more attention to the mines of Tuolumne and Calaveras. Among the encouraging signs of development may be mentioned the late discovery of several promising quartz lodes, and the construction of the necessary machinery to thoroughly test their value. Several companies have also been formed to work gravel deposits. A company of this kind, which has lately been organized to test the richness of the well known Table Mountain gravel range, east of Murphy's, in Calaveras county, is deserving of success, for the reason that it has commenced operations on a scale that shows confidence in the undertaking. This company uses 400 inches of water, which is forced through a six-inch nozzle under a pressure of 250 feet. The appointments for working are complete, and the immense quantities of gravel that can thus be worked will undoubtedly render the enterprise a profitable one. Similar enterprises are about to be inaugurated in other portions of these mining districts, and should they be successful (and there is great reason to believe that they will be) the gold yield from these two counties will be greatly increased and a new era of prosperity will be commenced.—*Stockton Independent*.

Colusa Quicksilver Mines.

We took a little run out to the mines the first of the week, but as our trip was one strictly on business, and as we had to return in a short time, we did not have an opportunity to examine all the mines. We went out to the Abbott mine to assist in locating a furnace and in surveying the necessary roads to and from the mine and the furnace location. Both the Abbott and Buckeye have contracted for brick, and have ordered the castings for a furnace each. They each expect to have their furnace in operation by the middle of September. In the meanwhile they are taking out rich ore. The Abbott has out now about one hundred and thirty tons of ore that will run on a low estimate three per cent., and another hundred tons of low grade ore. The Buckeye has out none of their richest ore, from the fact that they have been assorting and retorting as they have taken it out; but they have out over two thousand tons of low grade ore. What they have out is worth at least fifty thousand dollars, besides the expense of running it through a furnace. The Abbott has two tunnels about two thousand feet apart, and out of each they are taking rich ore, and on the ledge five or six "prospect holes" have been made, in each of which the cincharr is found, so it is a tolerably certain proposition that they have a ledge the entire length of their claim. It is situated on the top of a high and steep hill, and they can, when necessary, see a tunnel fully five hundred feet below the present workings. The Buckeye has one tunnel five hundred feet long, out of which they have taken and worked up a great deal of very rich ore, but they have simply taken it out of the tunnel and have not worked on the ledge above and below it. They are now running a branch of the same tunnel in another direction. These are the two best developed mines in that region, but there are others without doubt equally as good when better developed. We were very sorry that we did not have an opportunity of visiting the Elgin, the Colusa and Etna, but after finishing work at the Abbott, we had only time to make a short visit to the Buckeye, which was immediately on our road home. We intend, however, to make another trip very soon and will then take a look at several others. From all we could gather, we are satisfied that the Elgin has prospects enough to warrant putting up a furnace, and it is more than probable that one will be put up before the rainy season.—*Sun*.

SCIENTIFIC PROGRESS.

Heat.

From the reports of a lecture by Prof. F. Guthrie, we learn that heat is now generally supposed not to be a distinct thing, hot an agitation of the particles of matter. According to this notion, particles of matter are moving amongst one another like gulls in a swarm, or like the heavenly bodies.

The intensity of heat of a body or its temperature, is the rate of motion of its particles amongst one another, and this is independent of their number, that is, the size of the body, and also of the weight of each individual particle. Whatever be the mass or weight of a moving particle, it can never, by one or more impacts, give a greater velocity than its own to another particle. So the temperature of one body can never be raised above the temperature of the body whence it gets its heat. And hence, also, any two bodies of unlike temperature acquire the same temperature when in contact.

The quantity of heat in a body, on the other hand, depends upon the size of this body, and both upon the velocity and mass of its particles (that is, on their momentum). Heat quantity, apart from size of matter, is molecular momentum. A blow with a hammer may drive a nail farther into a board than the impact of a pistol ball. So there may be as much or more heat in a heavy particle moving slowly (cold) than in a lighter particle moving more rapidly (hotter). Capacity for heat is molecular inertia. Specific heat is the ratio of molecular inertia.

When a body receives heat, its particles are thrown into more violent motion. Most frequently this is followed by an increase in the orbits of the particles, which results in an increase in the general size of the body. Such is expansion by heat. Sometimes, however, as with water below four degrees C., the body shrinks as it gets heat, showing that the increased rate of vibration is not accompanied by increased orbit size. Conduction of heat is the spreading of molecular motion like agitation in a crowd. When heat is produced by burning, the particles of oxygen unite with those of carbon, and form compound particles; the greater the attraction between the two, the closer they get together, and the more rapid is their motion, just as those planets move fastest around the sun which are nearest to it. On rubbing two pieces of solid matter together, the particles of both are set in vibration, and heat is produced. Such is heat of friction. The same amount of work spent in overcoming friction always produces the same amount of heat. Accordingly we can measure the quantity of heat which corresponds to a given quantity of work exhausted.

If a force of a kilogram acts upon a kilogram weight for one second of time; in other words, if a kilogram weight be let fall for a second, it is found to fall through 16 feet, and then to have a velocity of 32 feet per second. If the weight be then stopped, the labor of stopping it is just equal to the labor required to lift it 16 feet. If the weight fall upon a hard body, so as to be quickly stopped, it becomes hot (witness the heating of bullets, against a target). The work which was accumulated in it (called kinetic energy) is suddenly transformed into molecular motion. The collection of particles, stopped in their onward motion as a whole, begin to move individually amongst one another with a greater velocity; in other words, the temperature is raised.

Whether we raise a mass of matter quickly or slowly, whether we raise it as a whole or piece by piece, we do the same amount of work, provided that at last the same weight is lifted to the same height. This work is stored up (potential) in the raised mass, and is given out as work done when the mass falls and overcomes obstacles. Whether the mass falls quickly or slowly, the amount of work due to its descent through the same space is always the same.

It is found that when 430 kilograms fall slowly through one meter, and in doing so overcome friction, the heat produced by the friction is sufficient to raise one gramme of water one degree centigrade. This is the mechanical equivalent of heat.

THE SUN.—According to Kirchhoff, the sun consists of a solid or partially liquid nucleus in the highest state of incandescence, which emits, like all solids or liquids raised to a white heat, every possible kind of light, and therefore would of itself give a continuous spectrum without any dark lines. The incandescent central nucleus is surrounded by an atmosphere of lower temperature, containing on account of the extreme heat of the nucleus, the vapors of many of the substances of which this body is composed. The rays of light therefore emitted by the nucleus must pass through this atmosphere before reaching the earth, and each vapor extinguishes from the white light those rays which it would itself emit in a glowing state.

PROFESSOR EYERSMAN has had occasion to examine at Kasan haillstones containing crystallized iron pyrites. The cause of this rare phenomenon, no doubt, was that small crystals of pyrites proceeding from the disintegration of a rock had been transported by a tempest into the clouds, where they were iced and converted into haillstones.

Spirit Photographs.

The mental effect which we term light is supposed to be produced by the beating of waves of ether against the retina of the eye. These waves enter the eye with an average velocity of about 186,000 miles in a second, the length of the waves being variable, from the one twenty-seven thousandth part of an inch to one seventy-five thousandth part of an inch. The retina therefore receives many billions of impressions in a second, and it is supposed that it is the difference in the number and velocity of these impressions that produces in the mind the sensations of the colors. If the waves which enter the eye have a much greater or a much less velocity than the limits above stated, they do not, it is supposed, produce the sensation of light; and the objects from which such rays come, although they may really stand before the eye, are, as we say, invisible. But although they do not effect the eye, they may impress the photographic plate, which has no such constitution as the eye.

One of the most successful methods of producing "spirit" photographs is to place, in front of the sensitive plate, within the plate shield, a clear sheet of glass, having nothing upon it except a thin positive of the "spirit" that is to be produced on the negative. The portrait of the sitter is taken in the usual manner. The light which enters the camera lens prints the sitter and also the "spirit" which is on the thin positive upon the negative. This is a very convenient method, as it requires no manipulations likely to be detected; and, as we think, the favorite plan practiced by the best "spirit" photographers. Prints made in this manner pass current among the believers for genuine ghosts of the departed, directly descended from heaven.

But a more new, interesting and scientific method of producing "spirit" photographs is as follows: The plain background screen, before which the sitter is placed in order to have his portrait taken, is to be painted beforehand with the form of the desired "spirit," the paint being composed of some fluorescent substance, such as a solution of sulphate of quinine. When this painting dries on the screen, it is invisible to the eye; but it sends out rays that have power to impress the photographic plate; and thus the image of the person together with the quinine ghost are simultaneously developed upon the negative. This is a very beautiful and remarkable method.—*Scientific American*.

TELEGRAPHIC PROGRESS.—When Franklin so arranged his wire across the Schuylkill river, near Philadelphia, that he ignited combustibles on one side of the stream by a charge sent from the other, he transmitted the first telegraphic message, and that too, in characters of fire. When Wheatstone so arranged his wires that he caused a magnetic needle in a distant city to point, at his will, to certain letters painted on a board, and thus to spell out the words of the message he transmitted, he first rendered the telegraph practically available for the purposes of business. When Morse caused a style attached to the armature of an electro-magnet to puncture, at will, an unruled hand of paper, and invented his system of short-hand, by which dots and lines were converted into words and phrases, he gave the telegraph to the people as a cheap means of rapidly communicating thought at distances however long. When House made the keys of his instrument the representatives of the articulate sounds, known to all languages, and when by touching the keys he printed at the other end of the line the letters expressing those sounds, he gave that precision to the process which seemed alone necessary to render telegraphy complete and perfect. And now, according to *Engineering*, M. Mayer, of the administration of telegraph lines, Paris, has an instrument by which he can send a message in his own chirography, and certify to its authenticity by appealing to it a fac simile of his autograph. We have already alluded to the telegraphing of sound, as explained at the last meeting of the California Academy of Sciences.

An alloy, to be used as a substitute in many cases for gold, is described in the French journals, and has already been successfully introduced. It is said to be capable of being cast, rolled, drawn, stamped, chased, beaten into a powder or leaves, and to be absolutely indistinguishable from gold, except by practiced experts. The article consists of one hundred parts pure copper, seventeen parts zinc or tin, six parts magnesia, nine parts tartar of commerce, one half part sal-ammoniac, and one-eighth part quicklime. The copper is first melted, then the magnesia, sal-ammoniac, lime in powder, are added little by little, and thoroughly mixed by a brisk stirring for half an hour, after which zinc is thrown on the surface in small grains, stirring it until entirely fused. The crucible is then covered, and the fusion maintained about half an hour, when the dross is skimmed off, and the beautiful material is ready for use.

ARTIFICIAL MANURE.—A new invention consists in obtaining soluble fertilizers from phosphates by treating them with the fumes of burning pyrites, or othersulphurous ores.

White crystal barrels have been introduced for various purposes in Europe.

MECHANICAL PROGRESS.

Manufacture of Gold Leaf.

The process of gold-beating is exceedingly interesting in its various details, and is one which requires the exercise of much judgment, physical force, and mechanical skill. The coin is first reduced in thickness by being rolled through what is known as a "mill," a machine consisting of iron rollers operated by steam-power. It is then annealed by being subjected to intense heat, which softens the metal. It is next cut up and placed in jars containing nitromuriatic acid, which dissolves the gold, and reduces it to a mass resembling Indian pudding, both in color and form. This solution is next placed in a jar with copperas, which separates the gold from the other components of the mass.

The next process is to properly alloy the now pure gold, after which it is placed in crucibles and melted, from which it is poured into iron molds called ingots, which measure ten inches in length by one inch in breadth and thickness. When cooled it is taken out in the shape of bars. These bars are then rolled into what are called "ribbons," usually measuring about eight yards in length, of the thickness of ordinary paper, and retaining their original width. These ribbons are then cut into pieces $1\frac{1}{4}$ inches square, and placed into what is called a "cutch," which consists of a pack of French paper leaves resembling parchment, each leaf $\frac{3}{4}$ inches square, and the pack measuring from $\frac{3}{4}$ of an inch to 1 inch in thickness. They are then beaten for half an hour upon a granite block, with hammers weighing from twelve to fifteen pounds, after which they are taken out and placed in another pack of leaves called a "shoder." These leaves are four and a half inches square, and the gold in the "shoder" is beaten for four hours with hammers weighing about nine pounds. After being beaten in this manner, the gold leaves are taken out of the "shoders" and placed in what are called "molds." These "molds" consist of packs of leaves similar to the other packs, and made of the stomach of an ox. After being made ready in the "molds" the gold is beaten for four hours more with hammers weighing six or seven pounds each.

The thinner the leaf becomes, the lighter are the hammers used, and it is also necessary in beating the gold, especially in striking the "mold," that the blow should be given with the full flat of the hammer and directly in the center of the "mold." The leaf, after being taken out of the "mold," is cut into squares of three and three-eighths inches, and placed in "books" of common paper. Each "book" consists of twenty-five leaves, and there are twenty "books" in what is known as a "pack."—*Iron Age*.

NEW GAS-ENGINE.—Messrs. Otto & Langen's machine consists of an upright cylinder, open at the top, in which plays vertically a piston having a ratcheted rod, so arranged as in the down stroke to engage a cog-wheel, attached to the axle of the fly-wheel of the machine. The piston, during a small portion of its upward course, takes in the rightly-proportioned mixture of gas and air, which is exploded at the point of the piston's course, where the mixture is shut off. Explosion of the mixture carries the piston upward until the pressure of the external atmosphere stops it. The explosion, depending on expansion of gases by heat at the instant of combination, is immediately followed by a condensation and partial vacuum in the cylinder. The pressure of the atmosphere upon the piston forces it downward, and the ratcheted rod, engaging the cog-wheel, imparts this force to the fly-wheel. It is claimed for this machine that it is much more economical of gas than M. Lenoir's. The complications incident to the ratchet and cog-wheel arrangement are objectionable; but it is spoken of as having quite an extended use. The consumption of gas is about a cubic meter (39.31 cubic feet) per horse-power per hour. With gas at \$3.50 per thousand, this would give ninety-six cents per day for horse-power.—*American Artisan*.

IMPROVED HEATING STOVE.—Thomas H. Salmon, Brooklyn, New York, patents an invention relating to stoves which have a draught through the fuel, consisting in the arrangement of a plate to form that side of the hanging grate which is opposite the smoke-pipe. Through a hollow standard a pipe passes upwardly into the combustion chamber. In the latter is hung the basket grate that is provided with a removable cover, through whose holes the air is drawn to produce the down-draught. One side of the basket grate is a broad plate, which comes directly between the smoke-pipe and the other part of the grate. By this construction, when there is sufficient heat to create a vacuum in the chimney, a current of air rushes into holes through fuel in the grate, under the plate, and into the chimney. In order to moderate the strong draught which is thus produced, slides in the ash-pan are moved so as to admit air.

A patent has been issued in France for surfacing and polishing mill rolls, by means of vulcanized emery wheel or mill with automatic rotation and to-and-fro motion, and which, placed in face of the roll to be surfaced or polished, performs the operation in a few minutes.

Gas Burning Locomotive.

The greatly increased cost of coal in England has called scientific attention to the economizing of fuel, and as an outcome of all the discussion and agitation, we have the numerous inventions for making and using gas that we have already noticed in this column. The latest invention brought out is designed to combine both gas making and using in one engine and at the same time. The locomotive is of the ordinary clumsy and awkward type used in England, except that there is no fire-box and that the tubes are quite large. Inside each tube is a gas pipe, with numerous jets on its upper side, and from these the gas escapes and burns in the tubes. Air is supplied at the rear end, and the product of combustion escapes into the stack in front. The gas is made by forcing atmospheric air into naphtha, petroleum or any other hydrocarbon, and collecting it in a reservoir or tank from which it may be pressed into the pipes precisely as pressure is given to ordinary street gas. The gas machine, oil tanks, reservoir, etc., are placed on the tender, and the air pump that supplies the air is connected with the cylinder at the front of the engine. The engine thus makes its own gas while running, and supplies its own fuel till the hydrocarbons are exhausted in the tanks. To get up steam and start the engine, manual power must be given to the air pumps till enough gas has been made to fill the reservoir. Another way, would be to supply the reservoir with gas from a stationary reservoir beside the track till steam was up. We have no data concerning the speed or hauling power of Mr. Walker's engine. We doubt if the experiment has gone beyond the wood-cut stage, but it is highly spoken of by the best English authorities, and very great things are expected of the invention. It can be also applied to all other kinds of engines, both marine and stationary, at a very great saving of expense and a great gain in storage capacity. Whatever the final results of this gas problem, Mr. Walker's patents will give the matter a great impetus in a new and unexpected direction.—*Boston Journal*.

IRON DAMS.—The Elmira, N. Y., *Gazette* urges a new departure in the method of constructing dams, saying: Masonry is but a little better than earthwork when opposed by rushing water. What is needed, it seems to us, is material which will not crumble or break up when attacked by rushing water. A dam might be constructed with a frame work of iron held by subterranean guys anchored beyond the reach of the water. The foundation could be planted in a rock bed, or in the absence of rock, against a system of piling, so as to be absolutely immovable. Thus strength would be attained. By planking the iron frame and covering the latter with earth or cement, tightness would be secured. This system would achieve one end at least. In case of a break in the dam, no disaster could follow to the region below, because only a small portion would give way and the water would escape comparatively slowly. The anchor could be so disposed as to render a complete giving way impossible, or at least improbable. The matter of cost and the process of rendering the iron durable as against rust, are matters for engineers and iron makers to consider. We believe that for dams as well as bridges, iron is destined to come into use.

FURNACES.—A new invention consists in making the furnace frame, a plate attached thereto, or the mouthpiece of the furnace dip down into the water contained in the evaporating or ash-pan, whereby access of air to the furnace in the ordinary direction is cut off. The air necessary to support combustion is admitted and regulated on each side of the furnace-door through openings which extend partially through the cheeks of the furnace and are carried down just below the fire-bars. The ordinary air way being closed, the cold air is compelled to enter the openings or air flues before mentioned, and in its passage abstracts the heat from the sides or cheeks of the furnace, thereby keeping them comparatively cool and increasing their durability.

WHAT is called the traveler's bed is an ingenious and useful article, manufactured in Germany. The article can be conveniently rolled up like a shawl, in a cylindrical form, twenty-three to twenty-seven and a half inches long, and from seven to nine and a half inches in diameter, the prices ranging according to size and quality. The bed consists of a light hair mattress, including single or double air pillows, a fine woolen coverlet, a camp stool, attachment and cords for adapting the mattress as a hammock, and apparatus for filling the pillows with air.

IMPROVED HOG TRAP.—This invention has for its object to furnish an improved device for catching hogs and holding them securely while being ringed, marked, etc. The hog, in seeking to escape through a gap in the trap, steps upon a tilted board, the tilting of which pitches him forward so that his neck may be between levers. The levers, by suitable mechanism, then close and clasp the hog around his neck, and around his body in the rear of his fore legs, where he may be held securely by hooking the straps upon pins.

EXPERIMENTS with a single track elevated railway have been made in Philadelphia, and pronounced successful by a number of railroad officials present.

ing finely, and the recent strike in the Original Amador gives promise of permanency, and the rock is of excellent quality. The Keystone, under the formanship of Mr. Parks, is looking as well as usual and is one of the best mines in the State.

CALAVERAS COUNTY.

QUARTZ LOSE LOCATED.—*Chronicle*, June 20: Messrs Peek and Cook of this place have recently located a claim on the celebrated Lefoy quartz lead, in the Jesus Maria district. The surface rock shows rich in free gold, and there is every indication that the ledge is a permanent one. The Lefoy mine is developing splendidly. Three shafts are being sunk, a depth of 40 ft. having already been reached. Good judges estimate that the rock will yield an average of \$25 per ton. Work is being pushed forward with unremitting energy.

EL DORADO COUNTY.

NEW MINING DISTRICT.—*Republican*, June 18: A new mining district, with C. M. Johnson as Recorder, has been formed in Kelsey township, this county, to be known as Onion Valley Mining district, and is bounded as follows: Commencing at the Reservoir and Pilot creek, thence running in a southerly direction to Saddle mountain, thence in an easterly direction along Silver creek to Onion valley road, thence in a northerly direction to the head of Pilot creek, thence in a westerly direction to the place of beginning.

INYO COUNTY.

BARTON.—*Cor. Independent*, June 13: Albert Mack's mill is running as regular as clock work. The completion of A. B. Williams' mill is fast drawing nigh. Mr. J. Wickland, foreman of the construction, informed me that "the mill in all probability will be ready to commence crushing a week from next Monday." Although there is no very elaborate work about the mill, it is substantial.

PROSPECTING.—An unusual number of persons are engaged in the Inyo and White mountain ranges east and north of this place, and we are told, with very encouraging results.

ARASTAS.—Dr. Griswold and others are erecting an arastra at Pinte district, the material for construction being procured at Bishop. The prospects of this district are very fair, and we hope this arastra may soon develop into a mill.

NAPA COUNTY.

THE MINES.—*Reporter*, June 20: W. C. Watson, on his late trip to the Geysers, passed through the mining region in which are located the Annie Belcher, Geyser, Kentucky, Georgia, Missouri, Flagstaff, and other mines. He brought with him specimens of ore from the above named mines, which afford abundant proof of their richness.

NEW MILL.—The Oalistoga Gold and Silver mining company are erecting a 10-stamp mill on their mine on Mount St. Helena. The site chosen for the mill is about 100 yards below the Lawly toll road, on the left hand side at the first water trough, about half way up the mountain. They have 25 men at work and expect to have the mill in running order by the first of August.

NEVADA COUNTY.

BUCKEYE MINE.—*Grass Valley Union*, June 21: The Buckeye mine, at Sweetland, is under the superintendency of George D. McLean. They are washing through the lower end of their tunnel, with 1,500 inches of water, while the upper part is being driven ahead. They are working three faces, one from the front and two from a shaft, and have had such favorable rock of late that they have made 60 ft. a week from all of them. But they have now struck a very hard slate rock in which it will be difficult to make more than six or seven feet a week in each face. After they run about 340 feet more they will raise a shaft to the surface, which will be reached in about 30 ft. The ground in front of this "raise" be all washed into the flume, thus forming an open cut. From the mouth of the tunnel to the Middle Yuba there is an ample fall, allowing them to have two falls of 100 ft. each, besides several smaller ones. These falls have an effect to break up the clods of clay, so that the water can wash it. Quite a large force is now employed, which will be increased when the tunnel is in.

MAGENTA.—*Tidings*, June 20: The run of the Larimer mill on Magenta rock for the month or so past has been a very satisfactory one, judging from reports, which say the rock is paying on an average about \$23 per ton, sulphurets yet to be worked. They are said to have a strong ledge of good ore in the third level, lately entered upon, and altogether the prospects are very encouraging.

THE Occidental mine on Brnsh creek promises well. The shaft is now down about 120 ft. and at this point the ledge is three feet thick and shows free gold with galena and sulphurets. Hundreds of mines are lying idle around here that only require work to bring them out to paying properties.

\$500 a week is being taken out of the California mine near Nevada, working a small force. This mine is proving a good one and under good management.

PLACER COUNTY.

OUR MINES.—*Placer Argus*, June 20: A good deal of activity is shown in working the mines around Auburn and we are glad to be able to state that the prospects for all of them may be considered good. One day last week we made a brief visit to Ophir and inspected the mines in that vicinity. Work on Bellevue is being prosecuted vigorously. Thirty-five men are at work now, and the connection between shaft numbers 1 and 2 has just been made.

About the 25th, stoping will begin, and the mill of the St. Patrick Co., which crushes the rock, will be constantly supplied with a good grade of ore. Fifteen men are employed on the St. Patrick mine, and though they are now in low grade ore, a prospect for a better quality is good. The stamps of the St. Patrick mill are rattling away at a lively rate, night and day, and several weighty bars of bullion showed that they had not been working in vain.

THE Orleans mine is $1\frac{1}{2}$ miles from Auburn. The ledge averages 4 ft. in width. The developments consist of 2 shafts, one 85 ft. deep and the other 75, and 104 ft. apart. The shafts are connected by a drift at 75 ft. The drift is now in 153 ft. The pay rock commenced at \$25 to the ton and constantly increased to \$100 per ton at the east shaft, since which it has steadily continued at that figure. Five hundred and eighty tons of the ore first extracted have been milled, paying an average of \$25 to the ton. There are now 200 tons of rock on the dumps that will mill \$100 to the ton of free gold, besides the sulphurets, which after being extracted assay \$1,000 to the ton. As the rock can be mined at a cost of \$2.50 per ton, it only requires a mill to make this one of the best paying mines in the State.

FOREST HILL DISTRICT.—Owing to the scarcity of water, a very small proportion of the richest claims in the district have been worked by the hydraulic process. The Dardanelles & Oro, owned by James, Dougherty and others, having the advantage of a full ditch of water belonging to this claims, have been enabled to keep three pipes running, working from 15 to 20 men, getting good pay. Young America, belonging to W. A. Freeman, is worked by hydraulic, the bed of the gravel which lies above the cement, and which will run from 20 to 40 ft. in depth. This claim is working eight men and is paying well. Washington claim, on Smith's Point, owned by Bernhard & Adams, is being worked both by hydraulic and drifting. It is working from six to eight men, and is paying well. Dardanelles cañon, owned by Cahill & Farrell, takes up the tailings from Dardanelles & Oro, by bed-rock flumes. Dardanelles bed-rock is being worked by a large company of Chinamen, supposed to be making good pay. Uncle Sam belongs to Fox, Fallon and others, who are getting good pay, drifting and crushing cement gravel.

The Jersey, owned by Reamer & Brown, continues to sustain its reputation as one of the best paying claims in the district.

BIG SPRING, owned by Newman, Pecht and others, is working from 6 to 8 men, regular pay and good prospects.

THE Emily, owned by Langstaff, Harper, Wilson and Lawler. During the past fall and winter they have run a bed-rock tunnel about 500 ft. in order to get fall, and are now taking good pay. Dr. Smith's claim, situated about half a mile southeast of Forest Hill, known as Seam or Vein diggings, which has not been worked on account of the scarcity of water, has recently been leased to Shorkey and Lathrop, who will work it on the shares. This claim prospects well.

LEWIS CASS COMPANY.—This company has recently commenced work on their quartz lode, situated about two miles west of Yankee Jim's. They have sunk a shaft 7 by 9 feet in depth, and have a ledge $6\frac{1}{2}$ feet wide, which carries a very large amount of sulphurets, and shows considerable free gold.

THE Pioneer Flume Company, of San Francisco, will put up two flumes of a mile in length during the present season. One of the flumes will be 8 feet wide, and the other half that size.

BEAR RIVER TUNNEL.—*Placer Herald*, June 20: We have read the following notice in not less than three papers this last week:

The enterprise originated by S. N. Stranahan and others, about a year since, to tunnel through from American to Bear river, Placer county, and thereby open up a section of mining country, to develop which would otherwise be impossible, has been incorporated under the name of the Bear River Tunnel, Fluming and Mining Company. Capital stock, \$10,000,000.

This may be true, and then again—there was much talk of this gigantic undertaking some time ago, but of late it seems to have died out. The above is the first sign of resurrection. We hope the company has been incorporated on a sure footing, and that it will prove successful, for there is nothing more certain, and we speak the opinions of men who ought to know, that the completion of such a tunnel would open up one of the richest and most extensive gold fields ever known to the world.

THE Crater No. 1 shaft has reached a depth, on the inclination of the lode, of 422 feet. Vein is found about fifteen inches thick, well defined and mineralized. At a depth of 372 feet, the vein made regular, and prospects well, the barren zone having been passed, and pay ore came in again, giving assurance of increased riches as depth is attained. The best gold mines in the State have had the same disturbance. What our mines require is deep working, of which we have notable instances in Amador and Grass Valley. Ore, of good quality, is being extracted from the topes above the 312-ft. level. The mill has just cleaned up and returned from 165 tons of ore \$4,100, about \$25 per ton.

THE BELLEVUE.—Connection has been made with shaft No. 2, 240-ft. level. Vein strong and ore rich. This portion of the mine will, within ten days, be ready for the extraction of high grade ore, at No. 4 and 5 shafts on the 100-ft. level. The stopers are at work extracting ore which speaks for itself.

PLUMAS COUNTY.

12-MILE BAR.—*Plumas National*, June 20: Capt. Corser, of Rich Gulch, is piping, and will have water until the last of July. His ground prospects for "big money" and Cap. Fred. Lewis, in the old McNeely claims, has discovered a new channel, or body of gravel, under a thick layer of serpentine, which is very rich and extensive. He will drift it during the summer. C. W. Hyde is working on the old bar, having brought a new ditch from Sebastopol creek. He is working a large lot of ground, has already made a good clean-up, and will have water for some time to come yet. The Rush Creek Flat claims have worked considerable ground, and the gravel is looking first-rate. They use a large-sized giant, have more water than they can use, and will have plenty all summer. The Halstead Bros., whose claim is directly back of Kingsbury's Ferry, have had a short run of water, with good pay for the work. They have a very deep and extensive bank of gravel, and when the water from Soda creek, now owned by the company, is brought to it, it will be one of the best gravel mining claims in the State. A number of small mining operations are running successfully, and the season in that section bids fair to be a very prosperous one.

SAN LUIS OBISPO COUNTY.

THE SANTA CRUZ.—*Tribune*, June 20: Mr. W. J. Lockhart, superintendent of the Santa Cruz quicksilver mine, broke ground this week, with a view of erecting a furnace at the mine.

SAN BERNARDINO COUNTY.

QUICKSILVER.—*Press*, June 20: A notice of the location of 1,500 linear ft. of cinnabar-bearing rock, in the Santa Ynez mining district, was filed in the County Clerk's office, Monday, by O. L. Abbott, also a similar notice by V. Cutter. These newly discovered mines have awakened a great interest here.

THE PIRU MINES.—*Index*, June 18: Mr. James H. Swift has returned from the Piru mines, where he has valuable interests in ledges of gold-bearing quartz. He reports active operations on the Piru. Messrs. Dyer & Wheeler, of Los Angeles, have about 30 Chinamen at work in their placer mines in the west branch of the Piru. Besides their usual work in the washings, they are putting in the flume, and otherwise preparing to carry on extensive placer mining operations. Treadwell & Co., on another branch of the Piru, are working their gold-bearing quartz vein at a profit of over \$20 per ton.

SIERRA COUNTY.

OAK RANCH.—*Mountain Messenger*, June 20: The company at Oak Ranch are working 8 men, in 4 shifts, and pushing their tunnel ahead as fast as it can be done. Less than 1,000 ft. will bring them to gravel, the richness of which they demonstrated by shafts.

HYDRAULICING.—McNaughton & Co. are slashing away at their bank in their claim at the City of Six. During the past year they purchased of Thos. Redman all the mining ground at that place, procured a "monitor," and fixed the diggings up in good shape, and now have 8 or 10 men at work.

MAGNOLIA MINE.—Work has again been commenced on the Magnolia mine. It always, when worked, paid about \$2.50 to the man.

The Smith Bros. are taking out about an ounce a day to the pick, at their diggings in Hog cañon.

WILBOURN & BURTON'S diggings at Woodchuck, near Gold lake, are paying better than ever this year.

INCORPORATION.—The old Mt. Vernon claim (the new name we forget), between Downieville and Forest City, is to be incorporated immediately, when its owners will proceed to develop it more extensively.

ST. CHARLES HILL.—Work has been recommenced at St. Charles Hill, in the claim from which some Frenchmen took a large nugget a few years ago.

PROSPECTS.—Good prospects have been obtained in the old "Higgins Claims," below Goodyear bar. A tunnel is in about 130 ft., where it taps a bed of gravel which prospects well.

NUGGET.—The Bald Mountain Co. took out a 30-ounce piece one day last week. This claim has yielded since it was opened about \$350,000, and has been in working order less than two years. It is pretty hard to beat.

Nevada.

WASHOE DISTRICT.

CONSOLIDATED VIRGINIA.—*Gold Hill News*, June 18: Daily yield, 300 tons of ore. The ore breasts on the 1,300-ft. level continue to yield splendidly, and promise a rich return for the future. The ore breasts on the 1,400-ft. level have been opened out 45 ft. in width in splendid ore. This does not comprise the width of the ore body, the vein on the east of this opening is still ore of a rich quality. At a distance of 65 ft. from the station, the south drift on the 1,500-ft. level has reached the ledge, showing the ore to be of rich quality. Arrangements are being rapidly completed.

ORPHE.—The extraction of ore from the 1,300-ft. level is still continued, the ore breasts opening out better than has heretofore been expected. The face of the south drift from the winze in cross-cut No. 1, on 1,300-ft. level is still in ore of a fine quality. It is expected that everything will be in complete readiness for the extraction of ore from 1,465-ft. level in a very few days. The dumps are all kept full, with a large reserve of ore on hand.

GOULD & CURRY.—Much better progress is being made with the north drift of the 1,700-ft.

level. This is caused by the use of the Burleigh drills, 28 ft. per week being now made where not more than half that distance could be accomplished in the same time by hand drills. The east cross-cut at the fourth station has penetrated a large body of quartz and low grade ore, but has not yet developed anything that will pay for the extraction.

SIERRA NEVADA.—The frame of the new hoisting works building is up and is being inclosed and the roof put on. The hoisting engine is being placed in position. The pumping engine will also be ready to place in position in a day or two more. The hydraulic is just fairly getting to work, and will soon begin to do some telling work. It is working with the utmost perfection. The ore breast throughout the upper portions of the mine are all looking and yielding well. The mill is kept steadily running on ore from the mine. Daily yield, 60 tons of ore.

GLONE CONSOLIDATED.—The ore at the north drift at the head of the incline is 1 ft. in width and of good quality. About 25 tons of ore per day is being extracted, which is being sent to the Excelsior mill for reduction. There is a large amount of ore in sight, and the future prospects are looking quite flattering. The machinery for a 20-stamp quartz mill is being manufactured to order in San Francisco. This mill will be erected at the mine and will save all cost of the transportation of ores. It is intended to run the mill with a compound engine.

HALE & NONCROSS.—The ledge on the 1,900-ft. level has been cross-cut and prospected for 200 ft. in width near the south line without yet finding the west wall. Some considerable streaks and seams of excellent ore have been encountered, all of which are wider and better at the bottom than they are at the top, seeming to indicate a fair prospect of widening out as they go downward.

BELECHER.—Daily yield, 550 tons of ore. The ore breasts throughout the entire mine are looking well and yielding splendidly as usual. The south drift from the Crown Point, on the 1,300-ft. level, is in 475 ft., the face in west country rock. The ore track from the ore body, on the 1,400-ft. level, is completed to the incline, enabling the hoisting of the ore through the company's shaft from that level, instead of through the Yellow Jacket, as heretofore.

CROWN POINT.—Daily yield, 550 tons of ore, which is being extracted from the 900, 1,200, 1,300 and 1,400-ft. levels. The ore breasts throughout the mine are yielding splendidly. The middle winze, from the 1,400-ft. level, is down 70 ft. vertically, the bottom in rich ore. The entire face of the north cross-cut on the 1,500-ft. level is in rich ore and improving almost every day. The main south drift on the 1,500-ft. level is being driven vigorously ahead to connect with the middle winze and the north drift on the same level from the Belcher. The main incline is down 82 ft. below the 1,500-ft. level in hard blasting ground.

JULIA.—The pits for the pump-bob, and the foundation for the new hoisting engine is about completed. The engine is calculated to be of 200-horse power, and the pumps, five in number, are to have 8-inch plungers, with a 6-ft. stroke each. Raising upon the third compartment of the shaft is making good progress.

DATON.—Day before yesterday a perfect flood of water was encountered in the south drift at the second station, driving the men out of the mine and stopping all work on the lower levels for the present. This flow of water is supposed to come from a portion of the ledge that is yet unprospected, and cannot certainly be of any very great duration. Fortunately the large supply of ore in the dumps will enable the mills to continue crushing until the water can in all probability be drained.

CHOLLAR-POTOSI.—Daily yield, 100 tons of ore, the assay value of which is \$30 per ton. This ore is mostly being extracted from the ore breasts in the old upper workings. On the fifth station level cross-cuts have been run both east and west on the ore body cut by the main south drift, in both of which the ore has almost entirely pinched out. An up-raise has also been made on the ore with no better success, showing thus far that the whole is nothing more than a bunch.

UTAH.—Sinking the shaft is making excellent progress. The south drift, on the 400-ft. level, is still pushed vigorously ahead, the face in quartz giving low assays, but the general appearance of the ground looking much more favorable for an ore development than at any time in the past.

OVERMAN.—The main west drift on the 1,200-ft. level is making $3\frac{1}{2}$ feet per day without change of interest to report. Sinking the winze from the 1,000-ft. level is progressing at the rate of three feet per day.

Occidental.—A new engine is being erected at the mouth of the north winze, nearly 2,000 ft. from the mouth of the old adit tunnel. The erection of the new machinery will now enable the draining of the water and a thorough development of the ore prospects.

BALTIMORE CONSOLIDATED.—The machinery has been repaired and started into full operation this morning. The erection of the new hoisting and pumping machinery is making good progress.

KNICKERBOCKER.—A heavy flow of water was struck a few days ago in the main west drift on the 450-ft. level, creating some delay, but which is again nearly drained, and the work in the face resumed.

CALIFORNIA.—The drifts are being run, one from the 1,400 and the other from the 1,500-ft. level stations of the Consolidated Virginia, to open and prospect those levels.

The Local Option Law.

In view of the large interest which has recently attached to the question of Local Option, and the importance that it should be carefully considered and fully understood, we give the law in full. Thus far, we believe, somewhere between forty and fifty elections have been held under the law, about thirty of which have resulted in favor of Local Option. By reference to another column it will be seen that the preliminary steps are being taken to call an election for this city. The law reads as follows:

SECTION 1. From and after the passage of this Act, whenever one-fourth of the legal voters of any township, incorporated city, or town, shall petition the Board of Supervisors of such county, or the county wherein such township, incorporated city, or town is situated, to call a special election, to vote upon the question of "Liquor License," or "No Liquor License," the Board of Supervisors of the county receiving said petition, shall within one month after said petition is filed with the clerk of said Board, make proclamation for the holding of said election in the township, incorporated city, or town, as may be asked for in such petition.

SEC. 2. The Board of Supervisors shall, by such proclamation, require an election to be held within each township, incorporated city, or town, as the case may be, on a day to be designated by such Board, and within thirty days from and after the day of issuance of said proclamation. Such proclamation shall be published in a newspaper printed in the township, city, or town in which said election is to be held, if there be one published therein, otherwise in a newspaper to be designated by such Board of Supervisors. Such a proclamation shall be published once a week for at least three weeks previous to said election.

SEC. 3. Said election shall be conducted and governed by the General Election Law of this State, so far as the same are applicable thereto, provided that copies of the Great Register need not be used, and section 1,056 of the Political Code shall not apply to or affect such elections. [Concerning proclamation by the Supervisors.]

SEC. 4. The tickets to be voted at such election shall contain the words "For License," or "Against License." If a majority of the votes cast at such election "For License" or "Against License," shall contain the words "Against License," then it shall not be lawful for any Court, Board or officer to issue any license for the sale of any spirituous, vinous, malt or intoxicating liquors in said township, city or town, wherein said election may have been held, at any time after the determination of the result of said election, provided that nothing contained in the provisions of this Act shall prevent the issuing of license to druggists for the sale of liquors for medicinal and manufacturing purposes.

SEC. 5. The Board of Supervisors shall meet as a Board within ten days after such election, for the purpose of canvassing the returns and determining the results.

SEC. 6. If at any such elections the majority of the votes cast "For License" and "Against License" shall be "Against License," then from and after the result of said election shall have been determined by the Board of Supervisors, it shall be unlawful for any person to sell or dispose of any spirituous, vinous, malt, or other intoxicating liquors in such township, incorporated city, or town at any time thereafter, until at any election, as above provided, a majority vote in favor of such license.

SEC. 7. No election shall be held under this Act oftener than once in two years.

SEC. 8. Any person who shall sell or give, or offer to sell or give, any spirituous, vinous, malt, or intoxicating liquors, in quantities less than five gallons, within any township, incorporated city, or town, contrary to the provisions of this Act, shall be guilty of misdemeanor, and for every such offense shall pay a fine not exceeding twenty-five dollars for the first offense, and not less than fifty or more than one hundred dollars for each subsequent offense, and be imprisoned in the county jail until such fine shall be paid at the rate of one day's imprisonment for each dollar fine.

SEC. 9. All fines collected under this Act shall be paid into the County School Fund of the county wherein collected.

SEC. 10. It shall be the duty of the County Judge to call the attention of every Grand Jury to the provisions of this Act.

SEC. 11. This Act shall take effect immediately.

TANNING OF TIMBER.—A communication on the important subject of timber preservation was made to the Academy of Sciences of Paris at its last sitting. The methods employed generally for railway sleepers in France are injection of sulphate of copper, or carbonization, the former probably to the larger extent; the quantity of sulphate employed for an ordinary sleeper of about 150 pounds weight, is from one to one and half pounds. The correspondent of the Academy proposes to substitute acid tannate of protoxide of iron, which impregnates the wood perfectly, and forms a true ink which preserves the timber admirably. The idea is not new, but we are not aware whether the process of tanning timber has ever been put in practice; perhaps the tanners might add it to their ordinary business.

APPLICATIONS are pouring in the Patent Office at a rate of over 600 a week.

Cheese as an Article of Food.

The claims of cheese as a wholesome, nutritious and economical article of food, have been ably and persistently urged upon the American people for a period of several years. Dairymen's associations have awarded ample prizes for the best essays on this subject, with a view to increase the home consumption of cheese; and physicians and writers on hygiene have rendered assistance that was at the time unopposed to be valuable. But the American people, to the evident disgust of the dairymen and their zealous champions, did not take to the cheese which was set before them, or rather to the cheese which was not set before them. There was a reason, however, at the bottom of the subject, or at the bottom of the pockets of the expected cheese-eating public, which the dairymen and essayist did not fathom—the public could not afford to eat cheese.

The cheese had been scientifically analyzed, and its component parts exhibited in due order; but the would-be consumers were more interested in the analysis of the contents of their purses. There were good reasons presented by the dairymen, showing that the people ought to buy more cheese; but the latter presented a counter reason which there was no getting around—they had nothing to buy with. These prize essayists will find no difficulty in convincing the masses that cheese is both wholesome

and nutritious; but they will earn their prizes before they convince the working people of this country that 25 cents paid for a pound of cheese is as economically expended as in bread, beef or bacon.

It was our good fortune, a few years since, to be present at the annual meeting of the American Dairymen's Association, before which a one-hundred dollar prize essay, on the subject—"Cheese as a wholesome, nutritive and economical article of food," was read by Prof. L. B. Arnold, of Ithaca, N. Y.; and an able essay it was too. This was followed by an address, by H. A. Willard, of Herkimer county, on the commercial aspects of the dairy. His great point was to induce the dairymen to use every effort to keep up the high price of cheese. He took the position that the higher the prices the greater would be the consumption; declaring that a "higher price for cheese would whet the public appetite for cheese." This "brought down the house;" but these same orators, and their applauding friends, would retire and meditate on the unaccountable backwardness of the people in adopting cheese as an article of food.

If a convention of manufacturers of dairy implements should offer a good paying prize for the best essay on the value of their wares, and have another party hired to get up at the

THE CALIFORNIA WATER THRUSH.

close of this advertisement and urge upon the assembled manufacturers the propriety of keeping up the prices of their wares, assuring them that the higher the prices the greater would be the demand for cheese-vats, cans, etc., how would the dairymen take it?

It is not expected that dairymen are going to make any material sacrifice for the sake of placing cheese, as a standard article of food, on the tables of the masses; nor should they expect that these masses will endure pecuniary martyrdom for the glory of American cheese. Their appetite for cheese does not need any whetting; it is already sufficiently sharp; but they are otherwise too sharp to pay as much for one pound of cheese as they pay for two pounds of choice beef, for ten pounds of flour, or for twenty pounds of potatoes.

This deprivation in regard to cheese extends through all portions of the country. Even the cheese-makers themselves, in the most prosperous dairying districts, use it only as a luxury. We may possibly be accused of going to the opposite extreme of the analytical and statistical champions of cheese alluded to above; nevertheless we venture the declaration that ten times the amount of cheese now consumed would find ready and regular purchasers if it could be brought down to the level of economical articles of food.

This is a matter worthy of serious consideration. In regard to some of our productions the question is continually arising—how shall we dispose of them? but with butter and cheese it is—how shall we multiply their production and diminish their cost?

During the year 1873 there were exported from Boston nearly \$200,000 worth of sewing machines, \$350,000 worth of agricultural implements, \$106,000 worth of carriages and parts, and \$1,274,800 worth of metal manufactures, machinery, hardware, etc., making a total of nearly two million dollars.

EXPERIMENTS are being made by an English railroad company to ascertain whether steel tubes can profitably replace those of copper and brass in locomotives.

The whole production of the precious metals throughout the world during 1873 is estimated to have been worth nearly \$220,000,000.

The Human Frame.

The Heart.

In this article we propose to take up the human organization and learn something of it; leaving comparative anatomy and physiology to future papers. First, then, let us get a correct idea of the position and functions of some of the more important organs of our bodies. The heart lies partly behind and to the left of the sternum, or "breast bone;" extending from the level of the third rib downward to a point an inch to the right of, and an inch below the left nipple; and never, under any circumstances, "coming up in the throat," or wandering around anywhere else. It is almost, if not entirely, destitute of nerve of ordinary sensation; its movements being regulated by means of motor nerves and the great sympathetic system, and so can not be felt under ordinary conditions at all. It can suffer violent inflammation without the possessor being aware of it, or feeling any sensation of pain; the increased frequency and power of the palpitations against the parietes of the chest first calling attention to it by means of the nerves in those parts. In rare diseases it becomes the actual seat of pain; but most of the sensations referred to it come from other parts—usually the stomach. "Heart-burn," a fair case in point, being a burning sensation at the pyloric orifice of the stomach, caused by a species of dyspepsia. It is diseased much less frequently than is generally supposed, being guarded by every means of protection it was possible for Nature to throw around it. Being a muscular organ, it of course must be subject to the general laws of muscular nutrition; hence in feeble or wasted conditions of the body it partakes of the general weakness and struggles violently or palpitates under muscular efforts which require increased action of it, but such palpitations are no evidence of disease. Dyspepsia is peculiarly subject to palpitations and heart-burns, and imagine they are suffering under some disease of the heart, when properly restored nutrition is all that is required to remove their unpleasant symptoms. Still the heart is not invulnerable to disease, and we should avoid any unnecessary taxation of its powers. All extremely violent or long continued exertion taxes its powers very much, and ought never to be indulged in unnecessarily. It is said that the Cornwall miners, who are accustomed to climb long series of ladders after a fatiguing day's work, are very subject to an insufficiency, or "leaking," as they term it, of the valves of the heart. And inflammatory rheumatism, if treated harshly, may fly to the heart, causing quick death, or leaving inflammatory deposits which ever after obstruct the proper working of the valves. Remember in rheumatism as in all other diseases, the nearer the surface you keep your trouble, the more easily handled and harmless it is. Wounds of the heart of any magnitude are necessarily fatal.

California Birds.

Water Thrush or American Dipper—(Cinclus Americanus.)

This California bird is remarkable for its partiality to brooks, rivers, shores, ponds and streams of water; wading in the shallows in search of aquatic insects, wagging the tail almost continually, chattering as it flies; and in short, possesses many strong traits of the Water Wagtail. It is also exceedingly shy, darting away on the least attempt to approach it, and uttering a sharp chirp repeatedly, as if greatly alarmed. It breeds in the higher mountainous districts, as do many of our spring visitants that regularly pass a week or two with us in the lower parts, and then retire to the mountains and inland forests to breed.

The voice of this little bird appears so exquisitely sweet and expressive, that one is never tired of listening to it.

The Water Thrush is six inches long and nine and a half in extent; the whole upper parts are of a uniform and very dark olive; the lower parts are white, tinged with yellow ochre; the whole breast and sides are marked with pointed spots, or streaks of black or deep brown; bill, dusky brown; legs, flesh-colored; tail, nearly even; formed almost like the golden-crowned thrush, except in frequenting the water, much resembling it in manners. Male and female nearly alike.

OLD MINING CLAIMS.—Captain Clark, with Mr. Higbie, Dr. Hays and several others, making up a surveying party, have returned to Los Angeles from a trip to the El Paso mining district. The object of the expedition was to survey some old silver mining claims which were worked a number of years ago, and abandoned on account of the Indians becoming troublesome. The El Paso regions lie south of Cerro Gordo and on the proposed line of the Los Angeles and Independence railroad. With the increased facilities for working, and the good indications, there is little doubt but there is wealth in the El Paso mines. Captain Clark has been instructed by the company, of which he is a member, to let contracts at once for working the claims, and operations will doubtless be commenced upon them before long.

The original patent for metallic tips for shoes was sold for \$100, and the company which bought it became wealthy. Now, upon its expiration, the inventor has obtained its renewal, and compels the company to pay him \$60,000.

USEFUL INFORMATION.

How Thermometers are Made.

The *Polytechnic Bulletin* thus describes the manufacture of thermometers at the Tower Manufacturing company's establishment, Chester, Pa.: The glass tubes, as received, are about a yard long. A boy nicks them with a hard steel knife, and breaks them into the lengths required. The bores, which are flat, are compared, by means of a lens, with those of ten standard sizes, and the tubes assorted accordingly. They are then passed to the blow-pipe table. Each glass blower has a foot bellows, and uses an oil lamp. Melting the glass at one end of a tube, he blows it into a bulb by pressing the sides of a hollow India rubber ball attached at the other, proportioning the size of his bulb to the bore of the tube, and ascertaining the size by using a pair of callipers. While the bulb is yet hot, the tube is inverted in mercury, which as the bulb cools, rises and partially fills it. The tube is then withdrawn and a short India rubber tube attached at its open end. Into this mercury is poured; that in the bulb is boiled to expel the air, which rises up through the mercury in the India rubber tube, and an atmosphere of the vapor of mercury now fills the glass tube and bulb. As this condenses, the mercury in the India rubber tube takes its place, when this tube, with any mercury remaining in it, is removed. The bulb is now warmed, and the open end of the glass tube hermetically sealed.

The bulb and a portion of the tube are immersed in melting ice, and the height of the mercury marked; they are then transferred to a bath at 62° Fahr., and the height marked; next to a bath at 92° Fahr., and the height again marked. The lengths of the three spaces of 30 degrees each are now carefully measured. If they are exactly equal, the bore of the tube is assumed to be uniform, and the degrees laid off on the brass scale of the thermometer are all made of the same length. If the spaces of 30 degrees each are not found to be exactly equal, then, by means of a highly ingenious dividing engine, the degrees on the scale are made to increase in length as the calibre of the tube diminishes. When the plate has been divided, and the figures and letters punched, it is passed, laterally, between rollers, to remove the burr left by the tools. Were it rolled lengthwise, the accuracy of the dividing would be impaired. The plate is then silvered and lacquered, the glass tube attached, and the whole slid into the well-known japanned tin case. The establishment turns out two hundred dozen thermometers a week.

WINE AND FERMENTED FRUIT JUICES.—The detection of malic acid is not sufficient to prove a sample of wine to be adulterated. The most certain procedure is to filter and add ammonia in excess. The fruit wines, when this has been done, deposit crystals, which adhere to the sides of the test glass. Genuine grape wine, on the other hand, deposits a powder, much less in quantity, not adhering to the sides of the glass; and, to the naked eye, devoid of crystalline structure. Dissolved in dilute acetic acid, the deposit from cider and perry contains lime and phosphoric acid. In grape wine lime is also present, but in smaller quantity. In this case, if the precipitate given by oxalate of ammonia is filtered off a fresh addition of ammonia gives a further precipitate. This is not the case with cider and perry. If perry and wine are mixed in equal proportions, a deposit of crystal is found on the sides of the test glass on adding ammonia. In cider and perry the phosphoric acid is present in combination with lime, while in wine it is combined with magnesia. The most characteristic reaction is that with ammonia.—*Mechanics' Magazine*.

GRAINING.—In describing the methods of imitating the grain of wood, we will mention only the simplest, that the miniated in the art may readily execute a fair specimen, without the array of tools employed by the professional grainer. The colors used in graining may be mixed in oil or distemper, the latter being preferable, for if not satisfied with the first attempt, it is easily washed off with water, and the work done over again. Surfaces to be grained should be painted with at least two coats of paint, tinted as follows: For light-colored oak, tint the white paint with yellow ochre, to a nice cream color. For medium shade oak, add a little number to the cream color. For dark shade oak, add umber and a little Venetian red to the cream color. The last coat, or ground color, should be made to dry with an "egg-shell gloss," not flat, that the graining mixture will not be absorbed, and thereby make the graining appear dirty.—*Am. Homestead*.

WINOWS FOR DARK ROOMS.—To light a dark room looking out on a narrow yard or street, let the glass be roughly ground on the outside, and set flush with the outer wall. The light from the whole of the visible sky, and from the remotest parts of the opposite wall, will be introduced into the apartment, reflected from the innumerable faces or facets, which the rough grinding has produced. The whole window will appear as if the sky were behind it, and from every point of this luminous surface light will radiate the room. The common window let into the wall takes only the reflection from opposite buildings.

Danger of Using Shot for Cleaning Bottles.

Fordos has recently directed attention to the dangers of lead poisoning where shot are used for cleaning bottles that are to be used for wine and other beverages. When shot are placed in a glass with water, carbonates of lead are at once formed, a portion of it being noticed as a precipitate in the water, while another portion of it attaches itself as a thin film to the sides of the vessel. This film adheres so firmly to the glass that it cannot be removed by rinsing with water alone, an acid being required to move it. When shot are used for cleaning bottles which are afterwards well rinsed out, the carbonate of lead suspended in the water will be removed, but that portion which is attached to the sides of the bottle remains, and is afterwards dissolved by the liquid placed in the bottle, if it possesses a sufficient solvent power. If the shot are only shaken up with water for a short time, it is scarcely possible for the carbonate of lead to become attached to the sides of the bottle, but oftentimes the shot are left in the bottle with the water for some time. Besides, the rinsing is not always done so carefully as it should be, and the carbonate of lead suspended in the water is not all removed. Fordos took four half-pint medicine glasses that had been cleaned with shot, and in one he placed white wine, in another red wine, in the third quinine wine, and in the fourth vinegar. After standing two days each was found to contain a considerable quantity of lead.

Another danger might also arise from shot getting lodged in the narrow creases at the bottom of certain bottles, when the action of an acid upon it would dissolve not only the lead but the arsenic which is always present in shot in sufficient quantity to render the liquids poisonous.—*Journal of Applied Chemistry*.

COAL.—An average Atlantic steamer consumes fifty tons of coal in twenty-four hours. Therefore, if five tons of coal are sufficient to feed an ordinary grate in our dwellings during the entire year, the coal consumed on board a steamer in one day will last a small family burning a good fire, ten years. If a load of coal be left out doors, exposed to the weather, until it is burned up in one grate, say a month, it loses one-third of its heating quality. If a ton of coal is placed on the ground, and left there, and another is placed under a shed, the latter loses about twenty per cent. of its heating power and the former about forty-seven per cent. The softer the coal the more it loses, because the most volatile and valuable constituents undergo a slow combustion.—*Iron*.

A CAR-LOAD.—Below we give a statement of what is in nearly all localities regarded as a car-load of transportation. As a general rule, 20,000 pounds or 70 barrels of salt, 70 of lime, 70 of flour, 60 of whisky, 200 sacks of flour, six cords of hard wood, seven of soft wood, 18 to 20 head of cattle, 50 to 60 head of hogs, 80 to 100 head of sheep, 9,000 feet of solid boards, 17,000 feet of siding, 13,000 feet of flooring, 40,000 shingles, one-half less of hard lumber, one-fourth less of green lumber, one-tenth less of joists, scantling, and all other large timber, 340 bushels of wheat, 360 of corn, 680 of oats, 400 of barley, 360 of flax seed, 360 of apples, 430 of Irish potatoes, 356 of sweet potatoes, 1,000 bushels of bran.

THE WASTE OF COTTON SEED.—Mr. Aikin, of South Carolina, says that the loss by neglecting to save cotton seed is immense; piles of seed are allowed to decompose and waste at nearly every gin house, and yet the seed is a valuable manure. For cultivating crops, 30 bushels of cotton seed in the drill, or 50 bushels broadcast, to the acre, will increase the crop considerably. Seed can be rotted by composting it in alternate layers of leaves, straw, and stable manure; 100 bushels of green cotton seed, mixed in bulk with a ton of soluble phosphate and allowed to remain a fortnight, will make a capital compost for 10 acres of any cultivated crop.

LITHOFRACURE appears to have been occasionally used by the German military engineers during the war in 1870, and its employment during the siege of Paris was specially referred to by the military correspondent of the *Times*. The composition of these several substances is now so universally known that it is perhaps unnecessary to give it. Lithofracure is, practically, dynamite under another name. It generally consists of nitro-glycerine, sandy earth, powdered coal, sulphur, sawdust, and nitrate of soda or nitrate of baryta.

PAINT FOR WOOD.—Wash the wood first with a solution of 1 lb. blue vitrol in 4 quarts water, then with $\frac{1}{2}$ lb. of yellow prussiate of potash in 4 quarts water. The resulting brown ferrocyanide of copper withstands the weather, and is not attacked by insects. It may be covered, if desired, with a coat of linseed oil varnish.

The following is commended as the best process of bronzing articles made of iron wire: Clean the wire perfectly and then immerse it in a solution of sulphate of copper until covered with a coating of metallic copper. Immerse the article in the following solution: Verdigris, 2 oz.; ea-ammoniac, 1 oz.; vinegar, 1 pint, diluted with water until it tastes only slightly metallic, then boiled for a few minutes and filtered. The articles are steeped in this liquor at the boiling point, until the desired effect is produced. Wash carefully in hot water and dry.

GOOD HEALTH.

Liebig's Extract.

In a letter to Joseph Bennet, Dr. Pettenkofer enters into an elaborate exposition, or rather vindication, of Liebig's extract. Like all alimentary novelties, that renowned preparation has had to fight its way into popular acceptance through at least two initial prejudices: first, a suspicion as to its wholesomeness, to use no stronger phrase; next, a scepticism as to its possessing any specific virtue whatever. Both these barriers the extractum carnis has at length surmounted, though three-and-twenty years have elapsed since its discoverer first produced it in the Royal Laboratory at Munich. How little its assailants understood the object of their attack may be inferred from the charges they brought against it. "The extract," said they, "containing as it does neither albuminoids, nor fat, nor hydrates of carbon, is not an alimentary substance." Of course it is not. It was precisely on the principle of eliminating from the extract every particle of albumen, of fat, even of gelatine, that Liebig proceeded. And with what result? To produce, not an alimentary substance strictly so called, but a condiment which has a distinct and unique place in dietetics. The role of condiments in the complex action of nutrition is but partially appreciated, and the most natural condiments are usually neglected for others much coarser, more stimulating, but really less efficacious. Voit, the most recent experimenter in dietetics, confirmed the popular impression that the flow of gastric juice to the walls of the stomach may be accelerated even by the sight of meat, as when he witnessed in a fasting dog, in which he had established a stomacic fistula, the immediate rise of the juice when he offered, without giving, the animal a bit of meat. Bouillon, he further maintained—warm and well-boiled bouillon—is the simplest and best digestive, and it is from this premise that Pettenkofer vindicates for the extract its paramount claims as a condiment. These it owes to the mixture of salts, different, indeed, but combined in definite proportions in a ratio which the organism imperatively demands, and the slightest deviation from which would constitute a veritable impurity. No amount of the best meat can take the role of the extract, any more than milk can play the part of cheese or butter. The product of Liebig is neither a nutrient nor an alimentary substance capable of economizing the albumen, the fat, or the carbo-hydrates; it is simply a condiment, but one of such efficacy that Pettenkofer does not hesitate to anticipate for it the chief place among such aids to digestion, not only in the sick-room, but in common every-day life. It has served him as a text for a very instructive essay on nutrition in general, and though much that he says is recapitulation, it is recapitulation of a kind that has a novelty of its own, from the clear and discriminating eye he passes along the series of discoveries bearing on the physiology and application of food.—*London Lancet*.

Food.

No more important questions can occupy the attention of the student of social science than those relating to human food. The advancement and development of the race depend primarily upon its aliment. And as man is the ultimate of all created earthly beings, so his food should be combined of the most progressed elements in earthly production. Vegetables contain all the elements composing the bodies of animals, but in a lower state of organization.

The muscles, nerves and brain power of man must be supported by nitrogenous food, and the more progressed and highly organized this food is, the more perfect will be the muscular power, the more delicate the nervous sensations, the keener and more profound the mental penetration.

Our ideas of digestion and nutrition become much simplified as we progress in chemical knowledge. It was once thought that the animal stomach possessed the power of metamorphosing its food into such elements as the system required, and therefore it was not material of what elements the food was composed, so that it be eaten with relish. But later science has demonstrated that the animal has no power of changing one element into another, and can merely use what it finds ready formed in its food. The vegetable elaborates—the animal appropriates. It then becomes of the highest moment that one should understand the elements of the food we use, and learn so to combine these as to produce the highest development of health, strength and personal beauty; thus attaining mental and moral culture.—*Ec.*

GYMNASTICS, while increasing the power and activity of the muscles, are of little advantage in warding off phthisis. Many erstwhile gymnasts have been victims to consumption. The swinging of heavy clubs about the head cannot be recommended. Less exercise than that with the arms causes hemorrhage in those consumptively inclined. Boxing puts almost too much strain on the heart and lungs, and it is questionable whether severe blows on the chest are ever of use. Bowling should be avoided by consumptives. Rowing tends to expand the chest, and, if no racing be undertaken, may prove of great value. Swimming should be used with great caution, as too long a stop in the water is apt by itself to bring on consumption.

Ozone.

Doctors differ widely as to the physiological effects of ozone upon the human body. That it acts upon the blood in some way is probable, but what special disease it causes, or what special disease it heals, is not yet ascertained. Some say that in an air which lacks ozone rheumatism may be expected; and it is asserted, and with great confidence, that the cholera is likely to come where ozone is wanting. There is reason for that assertion, which we shall presently mention, but it has not been fully proved by observation. Others say, on the contrary, that the irritation of this pungent gas will show itself in skin disorders, will send out blotches, eruptions and fire on the cheek and forehead; that ozone poisons the blood while it stimulates, and is to be classed with gin and whisky. Not enough is yet known of its medicinal effects to bring it fairly into the pharmacopoeia; and happily it cannot be kept on hand by the druggist, cannot be rolled into pills, or bottled for future use. Sunshine may be stored away in coal beds, but ozone is slippery, and disappears mysteriously, like the ice of carbonic acid. Only general assertion can be made concerning ozone in pathology, that on the whole, other things being equal, a lack of this influence in the air weakens the constitution, takes force out of nerve and muscle, and so predisposes the system to take on disease, and makes contagion more dangerous. More certain is the effect of ozone as a purifier in the air. No fluid acts more positively in decomposing and dispersing offensive substances. If its own smell is positive, it speedily drowns other more disgusting odors, and substitutes what is comparatively sweet and clean. It puts ammonia and sulphureted hydrogen, the odor of the stable and pit, out of the way more effectually than the chlorides. No disinfecting substance works so swiftly and so thoroughly as this attenuated shade of a substance. Dr. Fox quotes Schoenlein as saying that "air containing one three million two hundred and forty thousandths of ozone is capable of disinfecting its own volume of air filled with the effluvia evolved in one minute from four ounces of highly putrid flesh!" Surely no marvel of homeopathic theory or practice can match this statement. It goes beyond the fiftieth or the one-hundredth dilution.—*Herald of Health*.

Poisonous Wall-Papers.

The poisonous effects upon the air of rooms of arsenical pigments on wall-paper have been generally ascribed to the inhalation of the dust, which was found to contain arsenic and copper; but cases of arsenical poisoning of this kind have occurred in which, on account of the moisture still present in the wall and the effectual fixing of the colors, this explanation will not answer. Upon these a recent series of experiments by Fleck throws some light. Air in glass receivers was subjected to the action of Schweinfurth green and arsenious acid by simply placing these substances beneath some bodies in a moist condition, and by applying them as a coating to others, with and without paper, potato and wheat starch being employed as pastes. After from eight days to three weeks, in different cases, the presence of arseniureted hydrogen in the air was unmistakably revealed by tests; and left no doubt that cases of chronic arsenical poisoning must be attributed not only to the mechanical mixture of arsenical compounds with the air of rooms in the form of dust, but also to the presence of this gas, resulting from the decomposition of free arsenious acid in Schweinfurth green. It was also found that the development of the gas is favored by moisture in the air and the presence of organic matter, especially that in the paste. Mold appeared on the paper in some cases, showing that arsenic is not a preventative of its formation, as often stated.—*Technologist*.

The symptoms of asphyxia by illuminating gas are discomfort, inclination to vomit, convulsive movements of the muscles, especially those of the breast, the skin is cold, the breathing and pulse irregular. The remedies recommended are exposure to free air, even if cold, irritation of the skin by vinegar, and the palms of the hands, soles of the feet, and the spine with a stiff hair brush, blowing air into the lungs. When consciousness returns, place the patient in a heated bed in a room with the windows open, and administer a few spoonfuls of Malaga, Madeira or cherry wine. A mixture of tartar emetic and Hoffman's liquor, flavored with honey-water and orange-flower syrup, is spoken of as an efficacious after the return of consciousness.

VENTILATION AND WARMING.—In a lecture on ventilation, lately delivered before the Franklin Institute, Mr. L. W. Leede gives the following practical directions concerning provisions for ventilation and warming in the construction of buildings: First, never have long underground fresh-air ducts. Second, never allow a sewer, soil-pipe, foul-air flue or smoke flue to come near the fresh-air supply-flue, for fear of some connection being made between them by carelessness or accident. Third, never heat a building exclusively by currents of warm air. Fourth, always put the heating-flues on the outside walls instead of on the inside walls. Fifth, endeavor strenuously to avoid the fresh-air chambers becoming a common receptacle for all the rubbish of a filthy cellar.

MINING SCIENTIFIC PRESS

W. B. EWER..... SENIOR EDITOR.

DEWEY & CO., Publishers.

A. T. DEWEY, OEO. H. STRONO.

San Francisco:

Saturday Morning, June 27, 1874.

TABLE OF CONTENTS.

GENERAL EDITORIALS.—Improved Mechanical Movement; Congress and the Mining Laws; Harrow and Clod-Breaker; Our Great National Anniversary, 401. California Birds, 406. Our Gravel Mines; Personal Notice Must be Sent to Every Shareholder! 408. Ore Concentration; Early Method of Crushing Quartz; Placer Mining in Mexico; Recent Patents; General News, 409. Ground or Underground; Patents and Inventions, 412.

ILLUSTRATIONS.—Improved Treadle for Sewing Machines; Harrow and Clod-Breaker, 401. The California Water Thrush, 406. Crushing Ore by the Old Mexican Process, 409.

SCIENTIFIC PROGRESS.—Heat; The Sun; Spirit Photographs; Telegraphic Progress; Artificial Manure, 403.

MECHANICAL PROGRESS.—Manufacture of Gold Leaf; New Gas-Engine; Improved Heating Stove; Gas-Burning Locomotive; Iron Dams; Furnaces; Improved Hop Trip, 403.

MINING STOCK MARKET.—Table of Daily Sales and Prices and Comparative Prices for the Week; Notices of Assessments; Meetings and Dividends; Review of Stock Market for the Week, 404.

MINING SUMMARY from various counties in California and Nevada, 404-5.

GOOD HEALTH.—Lisby's Extract; Food; Ozone; Poisonous Wall-Papers; Ventilation and Warming, 407.

USEFUL INFORMATION.—How Thermometers are Made; Wine and Fermented Fruit Juices; Grainings; Windows for Dark Rooms; Danger of Using Shot for Cleaning Bottles; Coal; A Car-load; The Waste of Cotton Seed; Paint for Wood, 403.

MISCELLANEOUS.—The Two-time Reunion; Smelting Operations at White Pine; The Wagon-road in Yosemite Valley Complete; Mining Development; Colusa Quicksilver Mines, 402. The Local Option Law; Tanning of Timber; Cheese as an Article of Food; The Human Frame, 406. The Comstock; Quicksilver in Santa Barbara County; Smelting at White Pine; The K K Mine; Lead Refining; The Industrial Exhibition; Coal Bay Coal; How to Kill Tobacco Worms; The Elastic Air Hammer, 410.

Removal.

July 6th, 1874, the business office of this Journal will be removed just one block east of our present location, to No. 224 Sansome Street, southeast corner of California, over the Bank of British Columbia, where we have secured large and elegant quarters. This removal is made in consequence of the sale of the building in which we are now located, to parties who will proceed immediately to demolish the present structure, and erect a new and magnificent block in its place.

OURSELVES.—With this issue, the MINING AND SCIENTIFIC PRESS completes its sixteenth year, and this number closes volume XXVIII. The copious Index in the last page in itself speaks of what we have accomplished for the past half year.

OUR ROOT CROPS.—We hear no more of the potato blight, but this, with other root crops, is reported to be suffering severely in some quarters from the ravages of the grasshoppers. In Santa Maria valley this pest has been particularly active; potatoes, turnips, and even some fields of corn and beans that were very promising, have been seriously damaged.

The legislature of Massachusetts has lately passed a law making it necessary that a dozen eggs weigh one and one-half pounds. This is a move in the right direction, and we hope all the other States may speedily follow the good example set by Massachusetts.

WON'T PATRONIZE LIQUOR SELLERS.—Marshall Grange, of Michigan, numbering 200 members, has resolved not to trade with or patronize in any way persons engaged in liquor selling.

L. LANDECKER, of Placerville, has a contract to supply 20,000 pounds of soap-root this season, and has put a large force of Chinamen at work digging it.

WILLIE CASWELL, of Los Angeles, has been appointed a cadet at West Point.

The Los Angeles honey crop is expected to amount to 200,000 pounds.

Our Gravel Mines.

Ever since the shallow placers of California began to fail, our people have been running after big things at a distance. The stampede to Nevada began in 1859, after the discovery of the Comstock lode. That and the succeeding few years drained our State of thousands of its hardy and enterprising population. Virginia grew into a flourishing city in a few months. The tide across Washoe overflowed Southern and Eastern Nevada; Aurora and Austin sprang into being; Utah, Arizona, Idaho, Montana, and every other accessible place on the Pacific Slope, was overrun by the eager searchers for that mythical mountain of solid silver, always nearly within grasp, but somehow never reached. Hundreds of lives were sacrificed, and many millions more of money spent than has been realized in those wild hunts after wealth. A few, a very few, were benefited, while the masses suffered the loss. All this while right at home, at their very doors, lay heaps of treasure inviting labor and capital to uncover it; which, if that capital and labor had been expended in opening our deep gravel beds and supplying them with water, would today have vastly exceeded the present gold product.

The remnant of this great army of prospectors come straggling back to their deserted claims, poor in pocket, with shattered constitutions and wrecked hopes, wondering why they ever should have been so foolish as to have left them to pursue a distant shadow. But the wonderful changes that have taken place in many localities strike them with astonishment. Where the surface ground was being washed when they left, by the two or three inch nozzle of the rude and imperfect machines, and the fifty inches of water, the Little Giant is hurling its four or six hundred inches under a heavy pressure against a bank that is crumbling away before it, and disappearing through the broad sluice-way and long tail flume, tumbling down the drops, and gliding over the undercurrents to the wonder and admiration of those gold miners of long ago. A new class of men have taken their places, and are using those great improvements with startling effect. Long and costly tunnels have been run into the channel, new ditches have been constructed on a higher level, and old ones improved and enlarged. Capital and labor is everywhere throughout our mines engaged conjointly in bringing about these wonderful results.

The writer has lately visited some of these locations, after some years' absence, and noted the changes. Plumas and Sierra counties seem to be in the van of improvements. Here the "Great Blue Lead" has been opened at numerous points, and activity prevails all along this section of this wonderful deposit. Near Scales' Digging, in the western portion of Sierra county, are several prominent hydraulic mines; among them is the Cleveland & Sierra Hydraulic Mining Company's mines, a corporate company, and managed by R. N. Williams, Esq., and yielding well. The company own a large body of gravel, and a fine water system; and it is believed that when the channel is fully reached it will pay the shareholders large returns. One mile south is situated the Fairplay Consolidated, which five years ago was broken up into a dozen or more segregated claims, and worked separately in the rude manner then prevalent, but is now one of the most completely arranged and promising hydraulic mines in the State. Up to June 1st, by partial clean-ups, it had yielded about \$20,000, and the owners are confident that this result would be doubled at the end of the season. They have adopted all the modern improvements, have spared no expense in opening and developing their mine, and supplying it with water; but evidently have made one mistake, in adhering to an old custom of running it during the daytime only. At night the washings cease, and water for ten or twelve hours is allowed to run to waste, when it ought to be kept employed, thereby proportionally increasing the yield; and by the expenditure of some \$30,000, two additional outlets could be made, and a ditch constructed from Canon creek that would supply double their present volume of water, which would render it one of the most productive properties of its class in the State. We understand this valuable property is being negotiated for by some parties in London; who, it is presumed, if the sale is consummated, will carry out those suggested improvements, and run the mine to its fullest capacity.

Going south from the Fairplay mine, along this great gravel range, we pass Council Hill, Brandy City, Camptonville, etc., to Park's Bar, on the main Yuba river. Here on the north bank of that stream is situated the Union Hydraulic Mining Company's mine. It is incorporated with \$3,000,000 capital, and is now being vigorously worked. Their possessions comprise over two miles of the dead river channel, and distant some four miles from Timbuctoo, Smartsville and Sucker Flat, so famous for their valuable hydraulic mines. The mine is opened by two outlets, which dump into the river; the length of the tail flumes is one-half and one mile in length, both of which are constructed in the most substantial manner, through which is flowing fifteen hundred inches of water, day and night, from four of Craig's Little Giants, under a pressure of 130 and 160 feet. The gravel bed at the point where the present washing is progressing is perhaps 100 feet in depth, which gradually increases

towards the center of the ridge, and is composed of a very fine looking "river wash," remarkably free from pipe clay and large boulders. The property owns two ditches, one of seven and the other of ten miles in length, with an aggregate capacity of 1,500 inches of water, which they draw from Dry creek. This water runs about six months of the year; but an additional supply is obtained from the Forbestown Ditch Company, who discharge their waste water into Dry creek above the head of the company's ditches, and sell it to the Union company at a very low figure. By this means the Union mine is enabled to continue washing with a full head, usually up to the first of September, or for nine or ten months of the twelve. Estimating from partial clean-ups to April 15th, the net yield of the mine for the year will be at least \$40,000. This mine, like the Fairplay, however, is susceptible of extended improvements, whereby its annual yield could be largely increased.

The mines in and around Timbuctoo and Smartsville are all running to their fullest capacity, and turning out more gold dust than ever before. So also with the mines at San Juan and Sweetland. At the latter place, Mr. G. D. McLean is driving ahead the Sweetland creek hydraulic mine with renewed vigor, and sending the English shareholders the wherewith to pay dividends. This was one of the first hydraulic mines purchased by an English company, and it has paid regular and satisfactory dividends for a number of years, and promises to continue this for a long time to come. This mine and the Birdseye creek, at Von Bet, Nevada county, and the Cedar creek, near Dutch Flat, have created a good feeling with English investors, for they have all been remunerative, which induced some of the shareholders to purchase the Blue Tent mine, Nevada City. This is the first season it has been worked under the new management, and so far has exceeded their expectations, and presents as fine a prospect for future profits as can be desired. The Little York mine, in Nevada, and the North America in Sierra are also owned in London, but as yet have not made a very good record; nevertheless strong hopes are entertained of their beginning to make good returns this season. If so, there will be a demand for good gravel mines in the English market next winter.

But these men have learned a sad lesson from the numerous American transactions, not of the most praiseworthy character, perpetrated in London within the last few years, and will be exceedingly cautious in their selections and negotiations with us; and it should be the sincere desire of every honest man in California, that our State does not fall into the same disgraceful category as Nevada and Utah. It is our best policy, if no higher feeling actuates us, to deal honestly with the representatives of foreign capital who seek an investment in our mines, for it is capital properly applied that we most need to develop and work the deep gravel beds which are now lying idle, and to extend, enlarge and improve those that are already being worked.

YAKIMA MINES.—F. M. Thorp, of Kittitas valley, arrived in Seattle last week, having made the trip via the Snoqualmie in three days. Mr. Thorp reports little doing in the Swauk mines—the Discovery company's claims and one other being the only ones worked. On the bare of the Yakima, prospects of a cent to the bucket have been obtained; and it is thought that profitable employment for a limited number of men may be had, during the summer months, on the stream.

The people of Dacotah have an abiding faith in the reported stories about the fabulous wealth of the Black hill region, and each year the desire to unveil the mysteries surrounding that enchanted spot grows stronger. An expedition is now fitting out to explore this region and ascertain whether this reputed El Dorado is a myth or not.

BRITISH COLUMBIA MINES.—A private letter from Kootenay states that what are supposed to be rich diggings have been discovered in a locality about eighty miles from French creek, in the Big Bend country. A crowd has started out from Victoria to prospect.

A GENTLEMAN of long experience in mining camps, who has been spending several days in Bingham, Utah, expressed it as his belief that the mines of that district will turn out from \$4,000,000 to \$6,000,000 worth of ore this season.

The California Pioneer Societies will celebrate the 25th Pioneer anniversary on the 9th of September. It is proposed to make an excursion around the harbor on the old pioneer steamer, "Senator."

The Santa Barbara Index reports active operations in the Piru placer and quartz mines. Treadwell & Co. are working their gold-bearing quartz vein at a profit of over \$20 per ton.

The Tenino (Washington Territory) Coal Company are pushing their mining operations vigorously. They have some 37 men in their employ.

The Chollar mine shipped \$13,000 last week; over 600 tons of ore were hoisted last week, assaying \$29 per ton.

It is reported that Charles Crocker will shortly supersede Governor Stanford as President of the Central Pacific Railroad company.

Personal Notice Must be Sent to Every Shareholder!

An amendment to the California Code imposes extra expense and labor upon corporations levying and collecting assessments, which, in nine cases out of ten, is useless. It takes effect July 1st, 1874, and provides that, in addition to the regular publication of the assessment and sale notices as heretofore, personal notice must also be served as provided in the following quotation from the law:

"The notice must be personally served upon each stockholder, or in lieu of personal service, must be sent through the mail, addressed to each stockholder at his place of residence, if known, and if not known, at the place where the principal office of the Corporation is situated."

In addition to this; the assessment and sale notices must be published in some (daily or weekly) newspaper devoted to general news.

No matter for whose interest this change was intended, it certainly will not tend to the business welfare of the publishers of daily papers.

After being put to the trouble and expense of sending a personal notice to every stockholder, we opine that judicious managers of mining and other corporations will choose a less expensive publication than that of a daily paper, to comply merely with the form of the law.

That the patrons of the MINING AND SCIENTIFIC PRESS may be perfectly assured that our paper is absolutely a legal journal for the publication of all corporation notices under the provisions of the amended law, we have consulted with some of the sonndest lawyers of the State who have invariably and unhesitatingly declared the Press to be entirely a legal sheet for such publications, as it is most certainly the most appropriate journal for publishing all mining assessments. A glance at the heading and contents of the Press will show that it is devoted to general news in part, while no paper on the coast is devoted exclusively to that subject.

We expect from this date to receive an increased amount of corporation advertising, as our charges for the same are less than one-half the prices charged by daily publications. We ask shareholders and officers of all corporations to canvass this matter, and order their advertising in a journal which circulates widely over our whole Coast, and extensively among miners and shareholders.

The other sections of the law remain as before; including the following wise and important provisions:

"No action must be sustained to recover stock sold for delinquent assessments, upon the ground of irregularity in the assessment, irregularity or defect of the notice of sale, or defect or irregularity in the sale, unless the party seeking to maintain such action first pays or tenders to the corporation or the party holding the stock sold, the sum for which the same was sold, together with all subsequent assessments which may have been paid thereon and interest on such sums from the time they were paid; and no such action must be sustained unless the same is commenced by the filing of a complaint and the issuing of a summons thereon within six months after such sale was made."

Free copies of the Amended Assessment Law will be furnished at our office. Legal information regarding the publication of notices will be freely given at our office, or our agent will call on secretaries if requested.

Blank notices will be furnished free for serving personal notices to shareholders. Printed notices will be issued on short notice, at a low price.

The Consolidated Virginia company are completing their arrangements for the erection of a large, powerful mill at the mine, which will save the great expense of transportation of ores, and be a vast benefit to the shareholders. The mills are all kept steadily running, and the future prospects of the mine are evidently growing more favorable.

CHARITABLE FUNDS.—The Louisiana relief fund now amounts to \$40,273.11; the Young Men's Christian Association Building fund to \$131,000; the Agassiz Museum fund to \$154,000; the Mill river relief fund to \$14,473; the Sumner Memorial fund to \$15,000, and more is wanted all round.

The Currency Bill has been signed by the President. This bill fixes the greenback circulation at \$382,000,000—adding to the present circulation \$26,000,000.

The Diegneno mine, southeast of Julian City, between the Carlot and Stonewall mines, cleaned up a crushing of 17 tons of rock last week, realizing \$575.

It is reported that a disease is prevalent in the vicinity of Antioch which is destroying cattle. The animal becomes dizzy, staggers about, and drops dead.

W. B. Ogden, of Sutter, brought into Marysville, on Tuesday, the first load of new barley of the season.

The Globe Consolidated mine, on the Comstock, is going to use a compound engine in the new mill to be built at the mine.

Several old copper mines at Oopper City, Shasta county, have been relocated and will be immediately reworked.

ANTIMONY reduction works have been established in this city.

A SARDINE packing establishment has been started in this city.

Ore Concentration.

We have frequently stated that the salvation of many of the mining districts of this coast, where low grade ores were this rule, would depend on cheap methods of concentration. In all localities remote from railroad facilities and where labor and fuel are high, and the ores of low grade, the miners can do better by concentrating their ores before reduction. Thus they get rid of the gangue, and by reducing 100 tons into ten, save materially in transportation and reduction. Of course the concentration must be done at a rate that will leave a good margin for profit. They have turned more attention to this subject in Utah, probably, than anywhere else, but in Colorado also it is attracting considerable notice.

We see by the *Rocky Mountain News* that a company has been formed in Denver, Colorado, for the purpose of concentrating ores. They propose to erect works at which the hitherto valueless low grade ore may be concentrated to a point where it may be smelted to the profit of the mine owner. The circumstance that heretofore low grade ores could not be worked profitably, has in various ways operated as a disadvantage to the prosecution of the mining interests in Colorado. Low grade ore mines have remained a dead capital, and the working of high grade ore mines has been impeded and often prevented by the accumulation of the poorer class of ores, resulting from hand-dressing of first-class ore, so that to-day many dumps are capable of furnishing thousands of tons of mineral, which present facilities afford no means to work to any advantage. This company claims by a method, which is no longer an experiment, having been demonstrated a success in European and eastern establishments of a similar character to work ore, assaying no more than \$15 a ton, so as to derive a profit from its concentration themselves, give a large margin to the smelter on its reduction, and leave a profit to the mine owner to an extent to render the mining of the ore profitable to him.

In Colorado the ores running under forty ounces of silver in most of the mining districts are nearly worthless, there being no market for them. Ores containing forty ounces are salable at about forty cents per ounce, but ores containing two hundred ounces per ton are bought by the smelters at about \$1.10 per ounce. Concentrating only five tons of ore will enhance the value of every ounce of silver in the crude ore from 40 to 110 cents, and thus make every crude ton worth \$25 more; or what is even more important, provide a market for low grade ores entirely worthless up to the time that concentration works are erected. The \$28 mentioned will be of course reduced by the cost of concentration. The charge for concentration by the company to which we refer will be about \$5 to \$8 a ton, and the miner can well afford to pay that charge, because there will remain a margin of \$20 under this operation in advance of the usual rates paid now.

The company, as stated in the *News*, has some peculiar features. The capital stock is \$100,000, divided into 1,000 shares. The stock is divided into "cash stock" and "premium stock." The "cash stock" is subscribed and paid for in cash; the "premium stock" is subscribed and paid for in low grade ore, assaying not less than \$15 per ton, and may be subscribed for only by mine owners of the district where the works are located. By a provision in the articles, no works are to be erected until the premium stock is subscribed for; then the cash subscribers are to pay their money. When the works are completed the subscribed ore is taken to the works, concentrated, and sold on account of the company, and the proceeds, as soon as possible, divided among the cash subscribers until they are reimbursed in their subscription. Until then no dividend can be declared. So that at the end of a short period the cash subscribers own their stock without any cost, and the ore subscribers have invested only their cheap ore; after which time both share in the profits of the works.

The Trustees of this company are E. P. Jacobson, President; J. Marshall Paul, President of the Miners' Association of Colorado; J. F. L. Sobirner, Superintendent of U. S. Mint, Denver; F. D. Hager (banker), Treasurer; F. M. F. Cazin, M. E. Secretary. Cazin's system of concentration is to be adopted in the company's works.

Early Method of Crushing Quartz.

For crushing ore, perhaps the first step above breaking it with hammers was that method shown in the accompanying engraving. This rude machine was used in Spanish countries before *arastras* came in vogue. It is used occasionally now as a temporary affair to test rock, but is laborious and slow. Usually the rock was burned and plunged in cold water so that it would crumble, before submitting it to this machine; but a spring-pole and mortar makes a much more efficient machine to test ore with than this old rude Mexican arrangement. No doubt the man who invented this apparatus thought he had made a long step in advance; and probably the *arastra* would have surprised him as much as a modern quartz mill would surprise the inventor of the *arastra*. The method of working by this rude machine is easily seen by referring to the cut.

Coke, for smelting purposes, is being imported largely into Eureka.

Placer Mining in Mexico.

In our issue of June 6th we made mention of the fact that the placers of La Cienega and Los Llanos, in Altar district, State of Sonora, Mexico, were about to be worked in accordance with the method employed in this State. The company who have become possessed of the large tracts of land in which these placers are situated, will, however, make practical working tests before taking steps toward bringing in a plentiful supply of water. This week, Capt. Samuel Tyler, Charles Tyler and Mr. Sewell left this city for these mines, with a suitable outfit, to test the value of the ground. They took with them a large-sized Knowles pump, a mile and a half of wrought-iron pipe, and all the materials necessary to thoroughly test the ground. The undertaking is a bold one, for the water they are to use, being lower than the placers, will have to be pumped up so as to get fall for sluicing.

They propose to raise the water by means of the steam pump, and then wash the dirt in sluices. The water is to be forced from an adjacent lake, but it is only necessary to raise it a short distance to get the required fall. These placers have yielded fabulous sums by "dry washing," but have never been worked with water. If the ground produces half the amount it promises, the owners will proceed to bring in water and hydraulic the banks, which are from 10 to 50 feet high. The mines are about 55 miles inland from the Gulf of California, but at an elevation of only a few hundred feet, and it will be practicable to bring the water from the gulf. The gentlemen owning these mines have put none of the stock on the

CRUSHING ORE BY THE OLD MEXICAN PROCESS.

market; and will thoroughly test the ground practically before procuring extensive machinery. The placers of La Cienega are to be tried first, as it is easier to let water upon that part of the ground. If successful, the owners will then test the placers of Los Llanos. Capt. Tyler, who recently returned from an extended trip to that section of country, tells us that there are many large tracts of rich placer ground thereabouts, but the scarcity of water prevents their being worked. It would take large capital to bring water upon them, and without it they are of no value. If the company now testing the placers of La Cienega should be successful in their undertaking, it will probably be the means of inducing others to take hold of these mines. Capt. Tyler does not entertain the slightest doubt that the ground will pay magnificently with water upon it, and expects to pay all the expenses already incurred, in a few days after he commences operations. Labor there is very cheap, and it will not be long before the pipe will be laid and washing begun.

MINERAL KING DISTRICT.—A dispatch from Visalia, dated June 22d, says: "Intense excitement prevails here to-day, owing to the recent discovery of reported fabulous wealth in the Mineral King district, sixty miles east of here. Returns received this morning of an assay of the croppings made for John J. Valentine, Superintendent of Wells, Fargo & Co., show \$135 per ton in silver and gold. The ledge is plainly in sight for six or seven miles and forty or fifty feet in width. An immense quantity of the rock from which the assay was made is above ground. The discoverers calculate millions of tons. There is an abundance of wood and water on the ground. A large party leave here to-morrow for the scene." This sounds like the reports made of the famous Barro mines in New Mexico, where there were millions of tons with thousands of dollars above ground, and instead of hoisting from below, the ledges cropped out so high that the ore would have to be thrown down into the quartz wagons. These mines never made any extra work for the miners, however. Mineral King miners had better be a little more modest in their reports at first, or the great public will scent "Arizona diamonds," or schemes of like character, and refuse to have anything to do with the district.

The Consolidated Virginia mine sent down \$90,300 on Saturday last.

Recent Patents.

Among the patents recently obtained through Dewey & Co.'s, MINING AND SCIENTIFIC PRESS, American and Foreign Patent Agency, the following are worthy of mention:

MACHINE FOR RIVING SHINGLES.—Daniel Shankland, Watsonville, Cal. This invention relates to a machine for splitting or riving shingles or shingles. The block of wood is secured in a carriage which feeds it uniformly to the saw or splitting knife. An arrangement for giving the knife a twist when it has entered the block splits the shingle off, and throws it clear of the machine.

ORE CONCENTRATOR AND WASHER.—Jonas B. Wilder, Sonora, Cal. Relates to a sluice section which is mounted on springs and given a peculiar motion and jar. The section has inclined diagonal grooves or channels passing across it which extend through the sides of the sluice. The tailings from the main sluice must pass through this mounted section. The peculiar motion and jar which are given to the section cause the sulphurets and heavy particles to travel up the inclined channels and through the sides of the sluice, where they are discharged.

PRUNING IMPLEMENT.—Rufus E. Farriington, Anaheim, Cal. This patent covers an improved handle for pruning instruments by which they can be more easily handled and operated while trimming the higher branches of a tree. It also covers improvements in the construction of the pruning instrument.

AIR COMPRESSOR.—Wm. H. Fanninley,

Eureka, Cal. Mr. Fanninley proposes to compress air by hydraulic pressure so as to produce either light, heat or force, and describes a system of connections with proper reservoirs by which the air may be transmitted from one point to another for the purpose of providing power or force for various purposes.

STAGE SHIP FOR THEATERS.—Samuel H. Chapman, Sacramento, Cal. This invention relates to an extension ship for spectacular effects upon the stage of a theater. The ship is so constructed that when first seen by the audience it is quite small and seemingly in the distance; gradually the hull of the vessel extends in length; gradually the masts rise; nearer and nearer the ship seems to approach, until, finally, it stands before the audience a full rigged ship, filling the entire space upon the stage. All this is done by men in the hull of the ship, who by turning a crank operate slides which lengthen the ship.

PACKAGE FOR AXLE GREASE.—J. G. Hucks, S. F., Cal. This invention relates to an open top metal can, which Mr. Hucks provides with a wooden cover, the edge of which is bevelled. This cover is crowded into the upper open end of the can so as to fit tightly. When the cover is removed the entire top of the can is open, so that its contents can be easily removed.

MECHANISM FOR MOVING LUMBER.—Tothammer & Osborne, S. F., Cal. This patent relates to a machine for moving lumber from one place to another; but its principal use is for unloading lumber from ships and depositing it upon the wharf or in the lumber yard, as desired. It consists of a series of jointed sections, having rollers mounted transversely across them. The rollers are rotated by a belt or gearing, and are provided with spurs or projections, so that the lumber is moved along from one to the other until it arrives at its destination.

BOTTOM HOLE SEWING MACHINE.—J. J. Graff, S. F., Cal. An improvement upon the Humphrey Bottom Hole Sewing Machine, by which the button hole is finished without taking the cloth from the machine, thus saving the trouble of finishing them by hand, as heretofore. The improvement is very simple, and accomplishes the finishing neatly and perfectly.

General News.

BILLS WHICH HAVE FAILED TO PASS.—The following are among the bills which failed to pass both houses of Congress at the late session: Hager's bill, granting right of way to the Sierra Iron company's railroad, and Joues' bill, for the cointage of 20 cent pieces.

The various measures for imposing an extra duty on imitation champagnes; the bill providing for the free admission of jute cloth, and returned grain bags and quicksilver, all failed with the tariff bill.

Tha bill abolishing the government charge for gold coinage.

The admission of New Mexico and Colorado as States.

Repealing the Pre-emption, and amendatory of the Homestead laws.

For the construction and repair of the Mississippi river levees.

McCrory's bill for the regulation of charges for railroad transportation.

All the land grant bills, and many hundred bills for the relief of individuals.

PACIFIC COAST APPROPRIATIONS.—The Civil Appropriation Bill, as passed, contains the following among other appropriations for the Pacific Coast: For life-saving stations, \$342,304; for statistics in relation to mines and mining, \$10,000; survey of public lands in Arizona, \$20,000; California, \$30,000; Utah, \$20,000; Nevada, \$40,000; Oregon, \$60,000; survey of Indian reservations, \$150,000; work at the Navy Yard, Mare Island, \$250,000; machinery and fitting up the new Mint, \$18,000; refinery in the new Mint, \$35,000; for fitting up the old Mint for a sub-treasury, etc., \$35,000.

The River and Harbor bill contains the following appropriations: For removing rocks and wrecks off the harbor of San Francisco, \$25,000; improvement of Oakland harbor, \$100,000. The Secretary of War is directed to have surveys made of the Sacramento river below Tehama, Feather river below Marysville, estuary in Santa Barbara channel, about two miles north of Point Muger, and the San Joaquin below Stockton.

TERRIBLE ACCIDENT.—A terrible accident occurred at the Central Baptist Church, in Syracuse, New York, a few days since. The floor of a room in the church gave way and fell into another room below, which was also crowded, killing some 14 persons, and more or less seriously wounding about 150 others. Cause, defective construction. A church festival was in progress at the time. The excitement in the community is very great.

THE GENEVA AWARD BILL has finally passed Congress, and a Commission has been appointed to distribute the awards. The Commission consists of Hezekiah Wells, of Michigan; Martin Ryerson, of New Jersey; Kenneth Rayner, of Mississippi; William A. Porter, of Pennsylvania, and Caleb Baldwin, of Ohio, at salaries of \$6,000 each—to continue for one year only, unless extended by order of the President.

A NATIONAL GRANGE FIRE INSURANCE CO.—An act to incorporate the National Grange Fire Insurance Co. has been introduced into Congress, which provides for the incorporation of a company with a capital of \$1,000,000. One of the provisions of the bill is that the company shall make full annual reports of its affairs to the officers of the National Grange of the Patrons of Husbandry.

PROHIBITION IN MASSACHUSETTS.—According to the telegraph, Massachusetts appears to be going back on prohibition. The Senate of that State has passed a License Bill, by a vote of 27 to 14. This vote is said to have been brought out on account of the damaging report with regard to the working of the Prohibition Law, made to the Legislature by the Police Court Commissioners of Boston.

THE POPE AND THE UNITED STATES.—The Pope is said to have remarked recently: "The United States is the only country where I am really Pope in the eyes of the Government. I am always afraid lest European governments shall oppose my acts; whereas I can freely send Pontifical documents to the United States without fear of opposition on the part of its government."

THE VALLEJO ELEVATOR.—The stockholders of the Elevator Company held a meeting in this city the past week, and directed the Secretary to take steps for legally dissolving the company, and distributing \$2,500 now in the hands of the Treasurer. The company sank about \$150,000 in the enterprise.

THE LOCAL OPTION WAR has fairly opened in Nevada county. Public meetings are being held in Grass Valley, Nevada, Forest Springs, etc. Mrs. Wm. K. Spencer, of Grass Valley, delivered an address on the question, which was a model of its kind—temperate and well conceived. It has been printed.

LOCAL OPTION ELECTIONS have been held in 69 townships, 49 of which have decided against license and 20 for license.

ROBERT WATT has had a patent issued for 10,000 acres of land in the Big Meadows, Plumas county.

THE RAILROAD is in running condition for a distance of five miles from Saucelito.

Mrs. WOODHULL spoke her piece at Stockton, on Wednesday evening last.

The Comstock.

In the introduction to the last weekly mining review of the *Virginia Enterprise* that paper says: The gradual increase of ore in the lower levels of our paying mines and the constant development in mines wherein prospecting is in progress of more and more favorable indications, must at some time arrive at a point and assume proportions to produce effects. Therefore, it is probable that it may be considered that the general outlook is at the present time sufficiently favorable to warrant some advance in the price of stocks. We have had no sensation in the way of a big strike in many months, yet there has been that which is better; we have had in the ore-producing mines such a widening and expanding in all directions of the ore-bodies, as they are followed downward, as has astonished all mining men. Of the Consolidated Virginia this is particularly true. The developments made in the lower levels of that mine are astonishing, and almost beyond belief. In the lower levels of the Belcher and Crown Point it seems that the more explorations are made the more ore is found; and in all these mines the ore is of wonderful richness. In other mines not now producing ore, the developments made are such as to induce the belief in the minds of not a few persons who are closely observing the mining situation, that ore might be found at almost any time at very short notice.

Our people would not be surprised any day to hear it announced that rich ore had been encountered in any one of half a dozen or so of our mines where we now hear only of what seems aimless and endless drifting—drifting on lower levels, on upper levels, and on all kinds of levels, but always along some wall. They cannot thus drift on forever; there must be some cross-cutting done one of these days. We are therefore safe in saying that at least half a dozen important mines along the Comstock are just now in such a situation that none of our people who keep any kind of track of mining matters would be astonished to hear to-day or to-morrow that rich ore had been developed in this one or that one of the number—for they are all in an "interesting situation." When drifts that are run along walls keep dipping into ore, it is a very good sign that there is something out of the main "stream" of the lead. Machinery of all kinds continues to arrive almost daily, and in all directions we hear of new works being erected. In the early days of Washoe, when a mining company had erected hoisting works, the starting them up for the first time was made the occasion of a grand jubilee. A grand collation was provided and spread in the new works, from half a dozen to a dozen baskets of champagne were furnished, and whisky and brandy were there by the gallon; half the people of the town—merchants, lawyers, physicians, preachers of the gospel, as well as mining men—were present. Now, new works are erected and are in operation a week before half a dozen persons outside of those directly interested know anything of the matter, and not even so much as the corks of a soda-bottle pops when the huge engines make their first stroke. The starting up of new works is now becoming a sort of every-day matter.

Quicksilver in Santa Barbara County.

The Santa Barbara Press says: One thing seems to be definitely settled. Our "back country" is rich in very valuable and available mineral products. A paying spot has been struck in the great "cinnabar channel," which is more or less quick with precious ore through a long extent of our coast range. The fact that in the rear of Santa Barbara a vein of unusual richness exists, has recently been confirmed by the testimony of the most accomplished mining experts, and by actual tests of the ore. These mines are not, in one sense, a new discovery; but the present state of the quicksilver market renders their development quite inevitable. Unless through the results of some monopoly in mercury these mines are subsidized, their ores will, before very long, be in process of reduction. The question of title may, as in some other places in California, embarrass the speedy occupation of this mining region by the most effective workers. A certain grant, not unknown to fame in this locality, is asserting its elastic claim to these cinnabar ledges. D. E. Jones holds, as we understand, a 10 years' lease from the owners of this grant, and is removing ore having from 10 to 50 per cent. of quicksilver. A San Francisco company has claims yielding from two and a half to 10 per cent. The latter percentage is considered a good paying one.

These mines are situated from 18 to 20 miles in the mountains at the rear of Santa Barbara. The region has a sufficient supply of wood and water to render a reduction of the ores feasible. A road from this city can be made at a moderate expense. There is reason to believe that the product of these mines may, at no distant date, rival those of the New Almaden and New Idria district.

Wm. D. Brown, Esq., who has recently explored this cinnabar region, finds confirmation of the most favorable reports heretofore circulated in regard to the probable wealth that will be unfolded. Mr. Brown's opinion is based upon thorough geological knowledge and an extensive acquaintance with mining matters which has made him a reliable expert.

A New York Central special train, carrying several officials of the road, ran the 81 miles between Syracuse and Rochester in 90 minutes.

Smelting at White Pine.

The White Pine News says: We have promised ourselves the pleasure of recording an apparently impracticable enterprise for several weeks, but have refrained from so doing through fear that a premature description might be a detriment to parties interested. However, now that no doubt can exist of a complete and perfect success, we are permitted to make the matter public. Some weeks ago a company of practical men, composed of miners, mill-men and engineers, thought they could make a success where others had failed, and accordingly lessened the Metropolitan mill, near this city, and commenced operations. Their capital was limited, composed principally of honest endeavors and practical knowledge, coin being an article sadly deficient, but they went manfully to work, with firm faith in the future of their enterprise. The institution on which their efforts have been directed was in a most dilapidated condition, and looked as though no amount of ingenuity could ever bring order out of the chaos that reigned, but, at this writing, a complete quartz mill is running and turning out bullion in quantities sufficient to ensure a rich return for their labor. The company is now prepared to purchase ore and give the market value for the same, or work rock for those desiring to live by rates, as announced in another column.

What a commentary is this upon the unsuccessful efforts of would-be manipulators of the precious metals! Four men, without capital, take an old, abandoned mill, and with nothing but practical knowledge and indomitable energy make a complete and paying success where scientists, even those from the classic shades of Freiberg, have ignominiously failed! So will it always be; so may our country, rich in minerals, be brought to a perfect and lasting prominence among the bullion producing sections of Nevada, and to such men as compose the company in question, and to such only, must we look for the future prosperity of our district. We earnestly trust our people may see in this enterprise a lesson which will teach them to forward by every and all means, the desires of those willing and competent to bring our country out from the "slough of despond" wherein she seems now to be laboring. Another company, composed of similar material, is soon to be formed for the purpose of smelting our base ores, and it is to be hoped that no obstacle coming from "a penny-wise and pound-foolish" policy will interfere with its success. Remember that the matter has come down to a question of necessity, and that we must do something to aid in the development of the district before another tedious winter shall be at our door, and that we need expect no aid from wealthy outsiders to assist us in our regeneration. Demonstrate, as we have often said, the simple fact, beyond a doubt, that our ore-bearing mines are extensive and that the ores can be worked as readily as those of our flourishing neighbor—Eureka—and no other efforts need be made to induce capital to come to us, as moneyed men will surely want to invest where a certainty of profit exists. We are in dead earnest about this thing, and shall do all in our power to arouse the people to a realizing sense of the situation. Let us not mope and mourn over the present dullness of matters generally, but be up and doing, remembering always that "God helps those who help themselves."

The K K Mine.

The Eureka Sentinel of the 14th has the following to say of the strike in the northwest drift of the 3d level of the K K mine:

This strike is one of the most valuable and important which has ever been made on Ruby Hill. It demonstrates to a certainty the brilliant future now opening before the K K, which, henceforth, must take rank among the leading mines of the district. We have heretofore remarked of the K K that, if ore was ever struck in sufficient quantities on the third level, the future of the mine would then become too assured a fact to be reasonably doubted. The ore body has already been penetrated several feet from the point where first uncovered, without exhibiting the least signs of giving out. The whole face of the drift is in it. The ore is also much richer than that which is found on the other levels—a fact which is worthy of notice as being in keeping with the data obtained from the deep in the Eureka Consolidated and Richmond mines. It has assayed as high as \$115 per ton, of 2,000 pounds. We will visit the mine again next week, when we hope to be able to throw additional light upon this magnificent development. The character of the ore bodies in the other quarters of the mine noted last Sunday has not undergone any other change since, than the most agreeable one of expansion.

Particularly is this the case with the stupendous body which has been recently opened up on the northeastern workings of the second level. We say stupendous, because its vast proportions are such as to entitle it to all the praise and wonder which the word carries with it. Considerable ground has been stoped and breasted out in this quarter during the past ten or eleven days, without any apparent diminution of the ore having taken place. The ore bodies in the neighborhood of the shaft are all doing finely, for the product maintains the same uniformity in measure. The teams haul to the furnaces the usual amount of 35 to 45 tons per diem. From the vicinity of the Cunningham shaft, Marcelina West, there are very

flattering accounts, indeed, the ore having become richer and more extensive than it has been found to be at any preceding period since its discovery. That the ore bodies are both descending and expanding in the K K, are facts now too well proven to admit of assertions doubt on the part of those who have each week seen and examined them so closely as we are certain we have.

Lead Refining.

[By the processes usually employed for refining lead, a considerable waste occurs, and the separation of the lead from other metals and impurities is rarely perfect. A new system, devised by MM. Payen & Renx, of Marseilles, France, is said to admit of refining lead without the formation of oxides, and has, according to the *Chronique de l'Industrie*, the particular advantage of permitting the collection of all foreign metals of which the value may be worth considering. The process is founded on the property which a bath of caustic hydrated melted alkali possesses in dissolving, or, at least, oxidizing successfully all the metals except three, by drawing them into a soluble scoria, in a state of igneous fusion. The three exceptions are lead, silver and gold. The metals united with the lead are, one after the other, removed by melted soda, the action of the bath being maintained first by a jet of steam, designed to restore constantly the water of the hydrate from which the metals gain oxygen, and urged, according as the metals are in a less degree oxidizable, either by blast of air, or, finally, by carefully measured additions of nitrate of soda. The theory of the reaction is as follows: By simple solution in water, soda abandons all the oxides which it holds in solution or suspension, and is evaporated and dried for use in the operation, almost without loss. The metals oxidize in the melted alkaline bath in the order of their affinity for oxygen, an order modified, however—1, by their particular affinity for soda; 2, by the action of affinity exercised by the largest mass present. Thus tin and the metals of platinum, although much less oxidizable than lead or copper, are attacked very rapidly, and before the latter in the soda bath, by reason of their propensity to act as electro-negative elements. Hence, also, in an alloy very rich in lead, the copper oxidizes first. Another phenomenon of not less importance is that the solutions of the oxides in the soda bath act chemically in presence of the reagents exactly as do the metallic salts dissolved in water. It is thus in this igneous solution—all the metals are precipitated, one after the other, in the inverse order of their solubility; and in the direct order they preserve each other from oxidation. In this respect, even insoluble reducing agents, such as charcoal, may be employed in the bath. The principal applications in the process are its adaptations, not only to the refining of lead and the extraction of silver by the zinc process from lead and argentiferous scoria, but the purification of argentiferous copper and old complex alloys; the treatment of ores of platinum, gold, silver, etc., of ores of chromium, etc.

The Industrial Exhibition.

J. H. Gilmore, special agent of the Ninth Industrial Exhibition of the Mechanics' Institute, expects to obtain a fine collection of California minerals belonging to Henry G. Hanks, for exhibition; also a number of well-arranged specimens of wood, native to the State, the property of Mr. Voy, at present in the State University Museum. A large collection of building stones has also been promised.

The Board of Managers have appointed the following Committees:

Building—A. R. Wells, J. P. Cartie and J. McDonald.

Antiquity—W. P. Stout, P. B. Cornwall and George Spaulding.

Power and Machine—C. Elliott, J. Speir, R. Snvage.

Printing and Advertising—G. Spaulding, R. Savage, W. P. Stout.

Rules, Regulations and Tickets—J. C. Patrick, P. B. Cornwall, A. R. Wells.

Music and Decoration—H. L. Davis, R. B. Woodward, C. Elliott.

Privileges—R. B. Woodward, P. B. Cornwall, G. Spaulding.

Police—P. B. Cornwall, H. L. Davis, R. Savage.

Circulars and Classifications—J. H. McDonald, J. B. Curtis, R. Savage.

Location—J. Speir, W. P. Stout, G. Spaulding.

The premium list of the Bay District Horticultural Society has been decided upon. The Board has ordered it to be printed for general distribution. The subscription up to date amounts to \$45,525.

LANTERNS of horn were used by both Greeks and Romans; they put lamps into them for the purpose of lighting themselves home on moonless nights. In England Alfred the Great made lanterns to guard his graduated candle for the wind. Guy Faux's lantern still exists in the Bodleian Library. At Oxford, also, we believe there is still to be seen a highly ornamented specimen of a lantern of brass, about ten inches high and five inches in diameter. It has a small door on one side. Light was emitted through five rows of holes, in each of which is set a piece of fine crystal. On the top is a large piece or knob of crystal, through which a handle, now broken off, was fixed to the cone.—*The Engineer*.

Coos Bay Coal.

A correspondent of the *Chronicle* writes as follows from Empire, Coos Bay, Oregon: The bay is reached easily in about 50 hours by well-appointed steamers plying between San Francisco and this place, the county seat of Coos county. Empire is a thriving town of some 600 inhabitants, possessing excellent hotel accommodation, fine stores, large saw and planing mill, shipbuilding yard, court-house, school-house, churches, etc., situated about six miles on the bay from the mouth of the harbor.

The next town of importance on the bay is Marshfield, some nine miles distant from Empire. This is also a live place, having one sawmill capable of turning out 40,000 feet of lumber daily; also an extensive shipbuilding concern, where the Messrs. Mattson are at present building a large ship for the coasting trade. Between the town of Empire and Marshfield the Messrs. Simpson of San Francisco have a sawmill and the most extensive shipbuilding establishment on the bay; it is called North Bend. The Messrs. Simpson have built here some nine or ten ships, and are, at present writing, completing the largest ship ever built on this coast. She will have a carrying capacity of 2,000 tons.

Of the coal mines already developed, I may mention the Eastport, owned by a company in San Francisco. The mine is located on the coalbank slough, about two miles from Marshfield, and but a short distance from the mine owned and worked by Messrs. Flanagan & Mann, called the Newport. Both of these mines are well developed and are under excellent management. The yield of the two mines is about 10,000 tons a month. The Eastport mine has paid regular dividends of two per cent. on the capital invested, and the Newport mine, still held in original owners' hands, has made them all rich.

Some nine miles from Marshfield, on the Isthmus slough, is located the property recently purchased by Jasper McDonald of San Francisco, upon which the Coos Bay (Oregon) Coal Company is formed. I have just learned that work is about to be commenced by this company, and regular shipments of coal may be looked for in about three months. Adjacent to this property I was shown a remarkably fine coal development on a tract of land claimed by a Mr. Darby, a lawyer of San Francisco, who has been here in the interests of capitalists. Whether he intends to commence operations soon I was not informed, but he has secured a property good enough to keep, and then be sure of enough to provide for all the rainy days he may ever experience in Oregon.

How to KILL TOBACCO WORMS.—A late issue of the *New York Tobacco Leaf* publishes a long article, from which this is condensed, on the use of cobalt and jimson (or Jamestown) weed as a certain exterminator of the tobacco fly, and earnestly recommends tobacco growers to use the remedy. The mode of using it is as follows:

Plant the jimson in spots through and around the field, three or four plants in a clump, about the time the tobacco plants are set out. When the jimson blooms, put two or three drops of cobalt solution in each bloom every evening; the fly will suck the poison, which is certain death. Cobalt can be procured from almost any drug store; dissolve one ounce in something more than a pint of water, put into a corked bottle, with a quill inserted in the cork. Every morning after using the solution, the bloomer charged the evening before should be pinched off, or the poison will reach the stalk and kill the weed. The *Tobacco Leaf* recommends that in every neighborhood, farmers club together and agree to use the remedy. The result will be, in a very few seasons, if faithfully used, that every such neighborhood will be comparatively free from the pest known as the tobacco worm. Tobacco planters in Kentucky, and the West generally, would do well to act on the suggestion. The idea is not new, having been earnestly recommended in 1869 by the Agricultural Bureau.

THE ELASTO AIR HAMMER.—The experiments of the past two weeks, by Wm. Manson, with his power hammer, have demonstrated that it can do all, and, in fact, a great deal more than was ever expected of it. As a quartz mill it is found to supersede the old style in time, from the fact that two stamps of this will crush as much, and probably more, than five of the old style. He has tried it as a drilling machine, through several hundred feet of small pipe, and finds that it loses less by friction than he expected. A patent for the principles involved has just been granted through Dewey & Co., of the MINING PRESS, covering the United States; and patents are granted or pending in the most of the civilized foreign countries. With the mill now on trial, Manson has succeeded in breaking in pieces several mortar bottoms; the last one tried, five inches thick, was broken in a short time into more than a dozen pieces. Work will be immediately commenced on a 200 pound hammer, for use in the blacksmith shop, connected with the machine department. The hammer will have a drop of 2½ to 3 feet, and will strike with a force of 1,000 pounds. It is to be used for heavy forging and working up scrap iron.—*Mountain Messenger*.

THERE are over fourteen and a half millions of children of the school age in this country. We spend annually for schools over \$95,000,000, and we employ 221,000 teachers.

NOTICE.

We certify that the partnership of Dewey & Co., doing business in San Francisco, California, is composed of Warren B. Ewer, George H. Strong and John L. Boone, all of whom reside in the city and County of San Francisco, and Alfred T. Dewey, who resides in Oakland, Alameda County, Cal.
San Francisco, Cal., June 3d, 1874.

WARREN B. EWER,
GEORGE H. STRONG,
JOHN L. BOONE,
ALFRED T. DEWEY.

STATE OF CALIFORNIA,
CITY AND COUNTY OF SAN FRANCISCO,

On this June 3d, 1874, before me, F. O. Wegener, a Notary Public in and for said City and County, personally appeared Warren B. Ewer, George H. Strong, John L. Boone and Alfred T. Dewey, known to me to be the persons whose names are subscribed to the within instrument, and acknowledged to me that they executed the same.

Filed June 5. W. HARNEY, County Clerk,
By W. STEVENSON, Deputy.
In witness whereof I have hereunto set my hand and affixed my official seal, the day and year first above written.
june 4t F. O. WEGENER, Notary Public.

WATER TANKS of any capacity, made entirely by machinery. Material the best in use; construction not excelled. Attention, dispatch, satisfaction. Cost less than elsewhere.

WELLS, RUSSELL & CO.,

Mechanics' Mills, Cor. Mission & Fremont Streets,
3v28-3m-sa

THE ONE-PLUNGER JIG,

Delivered on R. R. Car at Denver, Col., or St. Louis, Mo.,

CONTAINING SIX SIEVES, END TO END.

Separate in one and the same operation—1. galena and sulphide of silver; 2. pyrites or blende; 3. tailings, containing no valuable parts; or, 1. gold; 2. pyrites; 3. tailings (quartz, etc.) containing no valuable parts; or, 1. copper; 2. tailings, containing no valuable parts. The One-Plunger Jig can be combined with existing stamp-mills with highly important advantages, as after amalgamation it will recover completely all fine metals and all base ores and all mercury out of tailings. It concentrates all fine metal ores to such cleanliness that low grade ores can be shipped, after concentration, as first-class ores. Its feed and discharge are automatic. Its construction offers better guarantee against loss and repairs than any other apparatus in use. For particulars, apply to the inventor, F. CAZIN, Mining and Civil Engineer, Denver City, Col.
L. Box 2225. 13v28-1y

cisco, and 113 J St., Sacramento. m8-ly

Ground or Unground.

A question has arisen, and is even now assuming considerable importance, as to whether our export wheat shall not be shipped in the form of flour. The proposition seems to have had its origin on this side of the water; and as there is supposed to be two sides to this, as to most other bargains, perhaps it would be well to learn how our foreign customers prefer to receive our wheat; whether ground or unground.

Those who are most strenuous in urging the shipment of flour instead of wheat, do not propose to so far anticipate the desires of our customers as to send them a different article from that ordered; they consider, first, which would be the best for us to send, then, if they are satisfied with it, why of course we will ship it to them. But we fear that they will not be as well satisfied with the flour as with the wheat. Flour is far more susceptible to injury than wheat. Every mishap that could befall wheat would be at least equally injurious to flour; while much that would be harmless to the former would be ruinous to the latter. The shell of the unground wheat protects it from odors; while these are readily absorbed by flour. The most delicate taints are extremely damaging to flour; and the exposure to dampness and various offensive odors during its transportation is, in the estimation of many, a greater risk than we can afford to run. Flour, it is true, has been shipped to Liverpool from California in moderate quantities within the past two years, the results being moderately satisfactory; but however favorable the reports from a few cargoes may be, it must, we think, be admitted that the risks involved in shipping flour are greater than in shipping wheat.

From our present knowledge of the wants of our English customers, we are justified in supposing that they would prefer to grind the wheat for themselves. We might, it is true, vary the manufacture of our flour so as to satisfy their peculiar demands, so far as our wheat alone will admit; but we are assured that California wheat is not of itself sufficient to satisfy the demands of the bread-eaters of Great Britain. They can buy no wheat that produces a finer looking flour; but in gluten it is declared to be inferior to that imported from some other countries. The system of mixing wheat is largely practiced in England; and in compounding a flour that comes up to their standard they use the California wheat to secure a good, attractive color to their bread; but for strength they rely principally upon that of other countries—the Australian in particular. English bread is undoubtedly of a more uniform character than our own. "Family flour," which forms the great standard in this country, is comparatively unknown in England, even by name; for families there do not make their own bread. It is the baker to whom they look for bread, as they do to the dairyman for the cheese to eat with it; and we must bear in mind that it is the baker who is to decide as to what is wanted there—he, of course, speaking for his customers, whose wants he is better acquainted with than we can possibly be.

One of the advantages expected from this proposed change from wheat to flour exportation, is the bran, which would undoubtedly be of great value, if we could retain it and get as much for our wheat without the bran as with it, as some evidently suppose. But this is an unreasonable expectation; for the bran is quite as valuable to those who are expected to buy our wheat as to us; probably more so, as they do far more "stall-feeding" than ourselves.

If our flour would be as acceptable to England as our wheat, and the risks in transportation were equal, it would be to our advantage, most certainly, to ship our wheat ground—especially if we could retain the bran.

Even the erection and fitting up of mills capable of reducing this enormous amount of wheat, would of itself give a great impetus to our manufacturing interests, while milling, as a permanent business, would furnish employment for a vast amount of capital and labor. In the matter of sacks also the advantage would be decidedly in our favor. Flour would be shipped in cotton sacks. This material we can grow ourselves, and we can manufacture it into cloth; and from the cloth we can make it into sacks.

A contemporary of a neighboring city, in urging a radical change from wheat to flour shipment, manifests its impatience by already casting about for sites for the mills that are to be erected. The paper alluded to having located in a neighboring city, it was to be expected that San Francisco would be cut off from all the anticipated advantages growing out of this change. It accordingly declares that San Francisco is in no way capable of becoming the center of this great milling enterprise. Those, however, who are better informed as to what our city is doing, and capable of forming a more correct estimate of its further capacity, declare that San Francisco is peculiarly fitted, both by natural and acquired advantages, for reducing California wheat to California flour. As large as is the amount of flour which we have produced within the past year, even her present milling power has not been employed to more than two-thirds of its capacity.

The shipping of flour instead of wheat is certainly a consummation devoutly to be wished, and it may possibly be brought about in time; but we do not anticipate more than a gradual change. California flour has the difficult task

before it of achieving a reputation in Europe. This task may be made less difficult by furnishing them with a good article to begin with. By neglecting this, the exporters of American cheese suffered material loss in the early days of cheese exportation; and some of our particular, but not fastidious customers, doubted our ability to supply their wants; while others questioned our integrity. Probably the latter charge was most applicable to the case. Let us not be led into the same error in shipping flour.

Oregon Pig Iron in the Market.

It is with sincere pleasure that we note the appearance in our markets again of Pig Iron manufactured on the Pacific Coast. While we had to bring the raw material seventeen thousand miles over the ocean we could have little hope of doing anything beyond satisfying our own wants in the way of Machinery, etc. Now, however, Oregon steps in with iron of superior quality and that sells for a higher price in the market than any English or American that we know of. The last importation of one hundred tons sold for \$45, \$4 higher than the average quality of Eastern or English, and \$9 higher than some qualities of the latter. This is not the first time that Oregon has entered the market as a producer of Pig Iron, but owing to adverse circumstances the industry had for a while to be abandoned. It is now resumed again, and there is a company represented in this city by General Allen, and will be able to produce about one-third of the quantity that is needed to supply the San Francisco market yearly. No doubt, in due course of time, other companies both in Oregon and California, will enter the market, the cost of production will be decreased, and our iron founders will be able to beat all other competitors in the Machinery and Agricultural Implement trade on the shores of the Pacific. An opportunity will also be afforded for the manufacture of hardware, and in fact the impetus given by it to the manufacturing industries of the coast can at this moment be hardly realized. When we can command iron and coal of good quality, and in abundance, we shall start in the race of progress as highly favored by nature as Pennsylvania, or Great Britain, and much more so than New York or New England.

ONE of Cochran's automatic ore feeders has been put in operation at the Sierra Nevada mill.

The last weekly clean-up of the Eureka (Grass Valley) mine, was 425 ounces of gold amalgam.

A TOTAL of 110,000 pounds of hullion was shipped from Eureka on June 17th.

PATENTS & INVENTIONS.

A Weekly List of U. S. Patents Issued to Pacific Coast Inventors.

[FROM OFFICIAL REPORTS FOR THE MINING AND SCIENTIFIC PRESS, DEWEY & CO., PUBLISHERS AND U. S. AND FOREIGN PATENT AGENTS.]

By Special Dispatch, Dated Washington, D. C., June 23d, 1874.

FOR WEEK ENDING JUNE 9, 1874.

FURNACE FOR REDUCING LEAD ORES.—Ebenzer Bassett, Hamilton, Nevada.

ELECTRIC SIGNAL APPARATUS FOR FIRE HOSE.—Joseph Buchtel, Portland, Oregon.

HARVESTER.—Melzar W. Coon, Plainfield, Cal.

NECK YOKE.—George C. McMullen, Suisun, Cal.

PROCESS FOR THE PRODUCTION OF LEAD PAINTS.—Charles C. Rueger, S. F., Cal.

MACHINE FOR PULLING COTTON STALKS.—James Sampson, S. F., Cal.

OIL-CAN FAUCET.—Frank Spinning, Steilacoom, Washington Territory.

CAR WHEEL.—James Pearson, Sacramento, Cal.

APPARATUS FOR PRESERVING FOOD.—John P. Schmitz, S. F., Cal.

TRADE-MARK.

MEDICINE.—John M. Connell, S. F., Cal.

"The patents are not ready for delivery by the Patent Office until some 14 days after the date of issue. Note.—Copies of U. S. and Foreign Patents furnished by DEWEY & CO., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest time possible.

A COMPLIMENT.

PLAINSBURG, MERCED CO., CAL., June 22, 1874.

DEWEY & CO.—Gentlemen: I herewith tender my grateful acknowledgments for the energy, promptness and efficiency which you have displayed in procuring my patent.

Although you were entire strangers to me when I first communicated with you, I soon felt satisfied you were gentlemen of integrity, and shall always be happy to represent you as such. Very truly yours,

H. W. RUCKER, M. D.

A Good Binder for \$1.50.

Subscribers for this journal can obtain our Patent Elastic Newspaper File Holder and Binder for \$1.50—containing full title of the paper on the cover. It preserves the papers completely and in such shape that they may be quickly fastened and retained in book form at the end of the volume, and the binder (which is very durable) used continuously for subsequent volumes. Paid, 25 cts. extra. It can be used for Harper's Weekly and other papers of similar size. If not entered, please, purchasers may return them within 30 days. Just the thing for libraries and reading rooms, and all who wish to file the Press.

The Mining and Scientific Press Marching Onward.

Our careful system of compiling, judiciously condensing, and conveniently arranging into regular departments, has been heartily endorsed. It renders the paper worth more to readers, who can find handily the which interests them most.

The weekly issues of the Press will contain reliable

Information for Practical Miners,

Treating on the Opening of Mines; Mining of Ores; Milling of Ores; Smelting of Ores; Separation and Roasting of Ores; Amalgamation; Saving of Gold and all precious Metals; New Processes of Metallurgy; New Discoveries of Mines; Mining Engineering and Hydraulics.

For Inventors, Mechanics and Manufacturers.

All new and important developments in Scientific and Mechanical Progress; Patents and Inventions of the Pacific States; Progress of Home Industries; Hints for Local Manufacturers; Illustrations of New Machinery; Reports of Popular Scientific and Industrial Lectures.

Our Mining Summary

Gives the progress of mining work from week to week in the various counties and districts throughout the principal mining regions of the United States, arranged in alphabetical order. It is the most extensive record of mining operations published in the world. It affords the intelligent miner a rare opportunity to know and profit by the work and experience of his neighbors. Miners have few sources of practical information in their calling, and should embrace every reliable means for improvement. Mining Operators and Shareholders, at home and abroad, weekly examine our Summary with increased interest and profit.

Our "Domestic Economy"

embraces new and important facts which should be known in every cabin and household. Short and interesting—the articles under this heading are freely read and practiced with profit and improvement to the readers.

The Press is not strictly a "paper for professional, scientific men," but rather a

Liberal and Popular Scientific Journal,

Well calculated to make practically scientific men from our intelligent masses. This is our stronghold for accomplishing good. Plain, correct and pleasing language, easily comprehended by all, confined mostly to short articles, is our endeavor.

For Self-Improvement,

Every issue of the Press abounds with articles of an elevating character, tending to the higher virtues and natures and progressive intellects of both men and women.

Hundreds of Dollars

Are often times saved to the readers of this paper by a single hint or article of information in its columns. Such instances have been repeatedly reported to the editors and proprietors during their long connection with the Press. Our paper presents

The New and Novel Developments

In the progress of this comparatively new section of the Union (but recently settled and now rapidly increasing with a population of the most intelligent and venturesome people, attracted from nearly every quarter and clime on the globe), enable us, with due enterprise, to display vigor and freshness in our columns not met with in similar journals elsewhere. The same circumstances also render such a paper more especially valuable to its readers in a new, and to a certain measure, untrodden field, where the best methods and processes of industry are not so well established or traditionally known as in older communities. Published experiences often save costly experiments and disastrous results.

A Great Variety of Industrial Information,

In brief and fresh form, suited to the wants and tastes of the readers of this coast, which is not obtainable otherwise so timely, or in so cheap and convenient form. As an industrial publication, meeting the wants of so many kindred industries, this journal stands pre-eminent and without a precedent.

Subscriptions payable in advance—\$4 per annum Single copies, post paid, 10 cents. Address

DEWEY & CO.,

MINING AND SCIENTIFIC PRESS AND PACIFIC RURAL PRESS OFFICE, 338 Montgomery St., S. F.

SECOND EDITION—REVISED AND ENLARGED.

The Explorers', Miners' and Metallurgists' Companion.

Comprising a Practical Exposition of the Various Departments of Exploration, Mining, Engineering, Assaying, and Metallurgy.

Containing 672 Pages and 83 Engravings BY J. S. PHILLIPS, M. E., Of California, a Practical Operator for Thirty-four Years; Explorer, and Resident in the Pacific States and Territories for the past Eight Years.

PRICE, bound in cloth, \$10.50; in leather, \$12. Forwarded by mail for 50c. extra, at the MINING AND SCIENTIFIC PRESS Office, by

DEWEY & CO.

HINTS FOR We will send on receipt of stamp for postage, FREE, our 32-page Circulars containing 112 Illustrated Mechanical Movements; a digest of PATENT LAWS; information how to obtain patents, and about the rights and privileges of inventors and patentees; list of Government fees, practical hints, etc. Address DEWEY & CO., Publishers and Patent Agents, San Francisco.

The Pacific Rural Press,
NOW IN ITS FOURTH YEAR.

ITS ISSUES CONTAIN

Sixteen well filled pages.
Original and Choice Engravings.
Editorials on Home Industries.
On various kinds of Stock-raising.
On Horticulture and Gardening.
Correspondence from Farming Districts.
Answers and hints to Correspondents about Local Farming.
Good Health and Useful Information.
Reports from Granges and Farming Clubs.
Mechanical and Scientific progress.
Agricultural Notes from all quarters.
Domestic Produce Markets.
Home Circle.
Domestic Economy.
Mechanical Hints and Domestic Receipts.
Home and Farm Matters.

Affording, in all, more of real instructive and profitable matter for general readers than any other weekly on this side of the Continent.

BROWELL'S PATENT CHIMNEYS.

Fire and Earthquake Proof, can be placed in any part of the house with perfect safety. Light and strong, so substantially put up as to render them impossible to be shaken down by earthquakes; can be used as Heaters and Ventilators, and are unquestionably superior to anything of the kind invented in the United States. Are recommended by all architects and Fire Insurance Companies.

J. BROWELL,
442 Jackson St., N. E. Cor. of Montgomery.

NONPAREIL OIL.

140 Degrees Fire Test, for Family Use.

OWNERS OF MILLS AND MANUFACTORIES, your attention is particularly called to this beautiful and safe ILLUMINATING OIL. Its use is urgently recommended by the New York Fire Commissioners and Insurance Companies. For sale to the trade in lots to suit.

A. HAYWARD, 224 California St.
19v23-3m

GIANT POWDER.

Patented May 26, 1868.

THE ONLY SAFE BLASTING POWDER IN USE.

GIANT POWDER, NO. 1.
For hard and wet Rock, Iron, Copper, etc., and Submarine Blasting.

GIANT POWDER, NO. 2.
For medium and sandy Rock, Lime, Marble, Sulphur, Coal, Pipe Clay and Gravel Bank Blasting, Wood, etc.

Its EXCLUSIVE use saves from 30 to 60 per cent. in expenses, besides doing the work in half the time required for black powder.

The only Blasting Powder used in Europe and the Eastern States.

BANDMANN, NIELSEN & CO.,
General Agents, No. 210 Front Street.

Designing

and

Engraving

at

This Office.

We are prepared to do fine Wood Engraving for illustrating Landscape Scenery, Buildings, Machinery, Works of Art, Manufactured Articles, Trade Marks, Seals, Etc. We have a first-class

Machine for Engraving

A portion of the work, which can be finished thereby more perfectly than by the eye and hand alone. Our patrons can depend upon first-class work always, and at reasonable prices. Samples can be seen at our office.

DEWEY & CO.

Our Agents.

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.

L. P. McCARTY—General Agent.
A. O. KNOX, City Soliciting and Collecting Agent.
W. H. RATTENBERRY—California.
CHAS. W. ORR—Solano County.
C. M. DALY—Colusa County.
ONAS. P. BELL—Alameda, Santa Clara and Santa Cruz Counties.
J. D. CARY—Sonoma County.
J. W. ANDERSON—Orange and Santa Ana, In Los Angeles County, Cal.
HOB. ALSTON—San Luis Obispo, San Bernardino and San Diego Counties.

To Mining Secretaries.

An amendment to Section 336 of the California Code, taking effect July 1st, 1874, provides that in addition to the regular publication of the assessment and sale notices as heretofore,

PERSONAL NOTICE

Must be served as provided in the following quotation from the law:

"The notice must be personally served upon each stockholder, or in lieu of personal service, must be sent through the mail, addressed to each stockholder at his place of residence, if known, and if not known, at the place where the principal office of the Corporation is situated."

The above refers to the ASSESSMENT NOTICE only. Advertisers in the MINING AND SCIENTIFIC PRESS will be furnished with copies of assessment notices printed on slips suitable for serving personal notice under this law at short notice.

DEWEY & CO., Publishers.

June, 1874.

Mining and Other Companies.

Order to the time necessary to mail the present latest edition of the M. & S. Press, we are obliged to go to press on the Friday evening which is the very latest hour we can receive advertisements.

Calaveras Gold Mining Company—Location of principal place of business, San Francisco, State of California.

PARKE & LACY,

Sole Agents for States and Territories west of the Rocky Mountains, 108 1/2 Leidesdorff street, Hayward's Building, San Francisco, Cal. 21v23-3m-hd14p

OVER \$3,500 PER MONTH SAVED

BY THE USE OF

HENDY'S IMPROVED CONCENTRATOR.

Can be seen at the Manufactory, 32 Fremont Street, San Francisco.

JOSHUA HENDY, Esq.—Dear Sir:—As a practical miner and millman, I take pleasure in recommending the use of your Concentrators in all mills where gold or silver ores are reduced. No mills should be without them for the following reasons:

1st. They are good sizers (no perfect concentration in pulverized ores can be effected without first sizing).
2d. The best Concentrator I have ever known—(the concentrated stuff only containing 5 per cent. of sand).
3d. They are good amalgamators, light (feathery) particles of amalgam and particles of coated gold, by attraction are brightened, and from their specific gravity and the action of the pan, fall to the bottom and adhere.

4th. They require but little power and attention to run them, and with ordinary care will last for years. I have been familiar with the workings of your Concentrators for four years past; have run them myself in the North Star Mine, Grass Valley; am familiar with their practical workings on the Empire Mine, Grass Valley; St. Patrick, Placer Co.; St. Lawrence, El Dorado Co.; Oaks and Reese, Mariposa Co., and most cheerfully give you this testimonial. For further information you are at liberty to refer to,

Yours respectfully,

JAS. H. CROSSMAN, M. E.

409 California street, or Cosmopolitan Hotel.

SAN FRANCISCO, April 27, 1872.

OFFICE SUPERINTENDENT OF KEYSTONE CON. M. CO., AMADOR COUNTY.

MR. J. HENDY—Dear Sir:—In answer to your inquiries as to your concentrators furnished our company last July, I would say that I am more than pleased with them; and the saving to the company has been over \$3,500 per month more than with the blankets and huddles formerly in use.

References:

Reference is made to the following mills, some of which have had HENDY'S CONCENTRATORS in use for over four years:

EMPIRE MILL. (8 Concentrators).....	Grass Valley, Nevada County.
NORTH STAR M. & M. CO. (8 Concentrators).....	Grass Valley, Nevada County.
VULTURE CO. (8 Concentrators).....	Prescott, Arizona.
NOY'S & CO'S MILL. (2 Concentrators).....	Prescott, Arizona.
LUCY MINING CO. (3 Concentrators).....	Owyhee District, Idaho
EL PASO CO. (3 Concentrators).....	Sonora, Mexico
ST. LAWRENCE MILL.....	Georgetown, El Dorado Co.
ST. PATRICK MILL.....	Newcastle, Placer Co.
JULIAN MILL.....	Newcastle, Placer Co.
VIRGIL MILL.....	Grass Valley, Nevada County.
KEYSTONE MILL. (22 Concentrators).....	Amador Co.

CAUTION—All of HENDY'S PATENT CONCENTRATORS are marked thus: "J. HENDY, Patented April 17th, 1866, and May 19th, 1868."

For full description send for Circular. Orders or letters of enquiry, address,

Office and Works, 32 Fremont street.

Mining District and Vicinity,

Showing the location of some 400 mines and tunnel sites, together with the mines surveyed for U. S. Patent. Price \$3. For sale and mailed to any part of the globe, on receipt of price, by A. L. BANCROFT & CO.,

A. ROMAN & CO., and LECOUNT BROS. & MANSUR, San Francisco. 10v26-1f

Machinery.

THE

AMERICAN TURBINE WATER WHEEL.

Recently improved and submitted to thorough scientific tests by James Emerson, showing the following useful effect of the power of the water utilized, being

THE HIGHEST RESULTS EVER KNOWN.

Percentage of part gate, 1/4 50.08; 1/2 69.64; 3/4 78.73; 1 82.53; 3/2 82.90. Percentage of whole gate, 83.14.

Mr. Emerson says: "These are the best average results ever given by any Turbine Wheel in my experience."

A splendidly illustrated descriptive catalogue, or any further information desired, furnished on application to

TREADWELL & CO.,
SAN FRANCISCO, CAL.

Sole Agents for the Pacific States and Territories.
ap15-1f

TO HYDRAULIC MINERS.

I warn Hydraulic Miners not to be misled by the advertisement of Mr. F. H. Fisher. Said Fisher has been heard in every suit to which he has been a party (respecting Patent Rights on Hydraulic Machines), whether as plaintiff or defendant.

His patrons have already paid over Five Thousand Dollars for license to use machines purchased of the self styled

"Only Reliable Party in the Business Who Protects His Customers."

Fisher's Machine is worthless unless the discharge pipe is furnished with appliances, the patent for which is owned by Messrs. CRAIG, and which Fisher is enjoined from making.

The Machine itself is also an infringement on another patent owned by the same parties.

All persons infringing on either of these patents

WILL BE PROMPTLY PROSECUTED.

I am sole LICENSEE to sell Machines manufactured under Craig's, Rice's, Macey's and Hoskin's patents.

I Guarantee Full Indemnity to all my Customers.

Machines of all sizes always on hand.

If you want a Machine that will give satisfaction, and do not want to pay for it twice over, buy an Improved LITTLE GIANT.

For further particulars apply to
